

SUSY searches with the ATLAS detector

Jeanette Lorenz

Ludwig-Maximilians-Universität München
Excellence Cluster Universe

12.12.2014 / GDR Terascale@Heidelberg

Supersymmetry (SUSY)

Supersymmetry: symmetry relating fermions and bosons

- Only possible extension of Poincare space-time symmetry.
- **Minimal Supersymmetric Standard Model (MSSM)**: each Standard Model particle receive a supersymmetric partner.
- Extended Higgs sector required.

Motivations for Supersymmetry (selection):

Can provide a dark matter candidate.

Solves hierarchy problem if masses of SUSY particles not too high.

Unification of gauge couplings

Production of supersymmetric particles at the LHC

[Prospino, http://www.thphys.uni-heidelberg.de/~plehn/includes/prospino/prospino_lhc8.eps]

Strong production of quarks (1st and 2nd generation) and gluinos

→ high cross section if masses not too high

→ Expected limits ~ 1.2 (0.7) TeV for gluinos (squarks)

Strong production of third generation squarks

→ Expected limits up to 0.7 TeV.

Electroweak production of sleptons and electroweakinos

→ might be most copiously produced at the LHC if squarks and gluinos heavy but electroweakinos light.

→ Expected limits $\sim 0.2 - 0.5$ TeV

Categorization of SUSY events

R-parity

→ Forbid baryon and lepton number violation by requiring *R*-parity conservation:

$$R\text{-parity} = (-1)^{3(B-L)+2S} = \begin{cases} +1 & \text{for Standard Model particles} \\ -1 & \text{for SUSY particles} \end{cases}$$

B: baryon number, *L*: lepton number, *S*: spin

→ Distinguish different categories: *R*-parity conserved, *R*-parity violated and long lived scenarios

If *R*-parity conserved:

- SUSY particles produced in pairs and decay until lightest supersymmetric particle (LSP) reached.
- LSP stable, only weakly interacting, neutral → dark matter candidate.
- LSP escapes detection → (large) E_T^{miss} .

ATLAS search strategy

Prompt					Long-Lived
R-Parity-Conserving			R-Parity Violation		Various ranges of lifetime
Strong 1 st , 2 nd gen. squarks, gluinos	3 rd gen. stop, sbottom	Weak EWK- inos, sleptons	RPC prod. RPV decays	RPV prod. RPV decays	

[<https://indico.cern.ch/event/352689/material/slides/0.pdf>]

Searches for strong production

⇒ Final states with (many) jets, possibly leptons and a (more or less) high E_T^{miss}

Analyses (selection):

- 0-lepton + 2-6 jets [JHEP 09 (2014) 176]
- 0 or 1-lepton + 3 b-jets [JHEP 10 (2014) 024]
- 2 same-sign leptons/3-leptons [JHEP 06 (2014) 035]
- 1 or 2 soft or hard lepton(s) + jets (to be published soon,
<https://indico.cern.ch/event/352689/>)
- ...

All searches use the full 2012 statistics of $\sim 20 \text{ fb}^{-1}$ collected by the ATLAS detector in pp collisions at 8 TeV.

[JHEP 09 (2014) 176]

Searches in final states with one or two leptons

<https://indico.cern.ch/event/352689/>

Four different analyses, requiring 1 or 2 electrons or muons:

- A 'soft' lepton ($6/7 < p_T(e/\mu) < 25$ GeV)
→ compressed scenarios
- A 'hard' lepton ($p_T > 25$ GeV)
→ medium to large mass splittings
- Two hard leptons
→ longer decay chains
- Two soft muons
→ specialized to minimal Universal Extra Dimensions

Signal discriminated wrt background by requirements on jet multiplicity, m_T , E_T^{miss} , m_{eff}

(Example from the soft 1-lepton analysis)

Major backgrounds ($t\bar{t}$, W +jets, Z +jets) estimated by:

- Defining control regions dominated by backgrounds to be estimated.
- Fit background model simultaneously to data in all control regions.
- Extrapolation to validation and signal regions.

Searches in final states with one or two leptons

<https://indico.cern.ch/event/352689/>

Results in agreement with Standard Model expectations.

Results interpreted in multiple supersymmetric models (both simplified and phenomenological).

Signal regions/analyses statistically combined to increase sensitivity.

Gluino masses $\gtrsim 1.2$ TeV/squark masses $\gtrsim 700$ GeV excluded for massless LSP, independently of the specific model.

Interpretations in cMSSM/MSUGRA

Interpretations also provided in full phenomenological models, e.g. in cMSSM/MSUGRA (4 parameters plus 1 sign):

- m_0 (unified scalar mass at M_{GUT})
- $m_{1/2}$ (unified gaugino mass at M_{GUT})
- $\tan \beta$
- A_0 (unified tri-linear coupling at M_{GUT})
- sign of μ

Gluino masses below 1.3 TeV excluded for all m_0 values.

→ Analyses nicely complementary.

Gluino mediated stop quark production

In 'natural' SUSY models: stop masses to be below ~ 1 TeV and gluino masses below ~ 2 -3 TeV.

(If stops and gluinos heavier, significant fine-tuning required and SUSY cannot provide a full solution to the hierarchy problem.)

→ Search for direct and gluino-mediated stop production.

Gluino-mediated stop production: Busy final state with four top quarks and E_T^{miss}

→ Four b-jets in the final state.

→ Analyses requiring b-jets particularly sensitive - as the analysis (in turquoise) requiring 3 b-jets in final states with 0 or 1 lepton.

$m_{\tilde{t}} > m_{\tilde{g}}$: Gluino masses up to 1.4 TeV excluded (depending on the LSP mass).

Searches for direct stop production

Often long and complicated decay chains.

Usually final states with many b-jets

Compressed scenarios:

- mono-jet searches
- soft lepton analyses

Can exploit final states with 0- 2 leptons

- Usage of complex discriminating variables
- e.g. exploit boosted topology to reject top background

Two examples for stop searches

Search for stops in final states with 1 lepton + 3-4 jets + E_T^{miss}

JHEP11 (2014) 118

- 15 signal regions covering many topologies: direct stop to LSP decay, 3- and 4-body decays,...
- Using a large collection of dedicated variables, including soft leptons and boosted jets.
- Sensitivity to stop masses up to 650 GeV.

Constraints from precision measurements of the $t\bar{t}$ cross section on light stops

Eur.Phys.J.C74 (2014) 3109

- Most searches have no sensitivity to stop masses close to the top mass.
- Can access this region through precision measurement of the $t\bar{t}$ cross section.
- Exclude stop masses below 180 GeV.

Summary on stop searches

Various analyses to cover gaps at top (and W) mass (difficult to access):

- $t\bar{t}$ cross section measurements.
- Search for \tilde{t}_2 with Z in final state. →
Eur.Phys.J.C (2014) 74:2883
- Measurement of spin correlation in $t\bar{t}$ events. →
ATLAS-CONF-2014-056

→ Searches sensitive up to stop masses of $\sim 700 \text{ GeV}$

Searches for directly produced electroweakinos

→ Direct chargino/neutralino/slepton production can dominate at the LHC if squarks/gluinos much heavier.

Clean signatures with: leptons (including taus), W/Z bosons and Higgs bosons + E_T^{miss} , low jet multiplicity

E.g. searches in:

- 3 leptons (e, μ, τ) + E_T^{miss} [JHEP 04 (2014) 169]
- 2 leptons (e, μ) + E_T^{miss} [JHEP 05 (2014) 071]
- 2 taus + E_T^{miss} [JHEP 10 (2014) 096]
- 4 leptons + E_T^{miss} [Phys.Rev.D.90, 052001]

Searches for electroweak SUSY with a Higgs boson

[ATLAS-CONF-2014-062]

Searches in 3 different channels:

- 1-lepton + 2 b-jets
- 2 same-sign leptons
- 1-lepton + 2 photons

Discriminating variables:

Combining the three searches + 3-lepton search:

Limits up to 250 GeV on the electroweakino mass for massless LSP

Status of searches for electroweakinos

- If decays are mediated by sleptons: limits up to 720 GeV.
- If via WZ: limits up to \sim 450 GeV.
- Little or now sensitivity to compressed scenarios.

(Be aware that in this plot many different simplified models are shown together.)

R-parity violating Supersymmetry

If R -parity violated:

- Condition: either lepton or baryon number conserved.
- LSP can decay (thus no dark matter candidate).
- No large E_T^{miss} as signature, but usually high object multiplicities.

4-leptons

Phys.Rev.D. 90, 052001 (2014)

- Analysis requiring 4 leptons, Z-veto and high m_{eff} .
- Backgrounds depending on τ -multiplicity in final state:
 - ▶ Irreducible for 0 τ : ZZ, VVV, $t\bar{t}Z$, Higgs
 - ▶ Reducible for 1-2 τ : Z+jets, $t\bar{t}$, WZ
- Limits reaching up to ~ 1.4 TeV in the gluino mass \rightarrow comparable to RPC searches.

Searches for long-lived particles

Long-lived particles appear in different cases, e.g.:

- Small RPV couplings.
- RPC: compressed scenarios.
- RPC: meta-stable and long-lived gluinos due to heavy squarks.
- RPC: long-lived sleptons/neutralinos due to small coupling to gravitino.

Result in distinctive signatures depending on lifetime:

- Displaced vertices, disappearing or kinked tracks.
- Leptons/photons not pointing to the primary vertex.
- Delayed decays of massive particles, ...

Heavy long-lived particles

[arXiv:1411.6795]

- Predicted by Split SUSY, GMSB, LeptoSUSY etc.
 - Long-lived sleptons, gluinos, squarks and charginos in the final state.
 - Significantly slower than light.
- $m = p/\beta\gamma$ used as discriminating variable.
- Main background: high p_T mismeasured muons.

ATLAS SUSY Searches* - 95% CL Lower Limits

Status: ICHEP 2014

ATLAS Preliminary

$\sqrt{s} = 7, 8 \text{ TeV}$

Limits on:

- Gluinos: $\sim 1.2 - 1.3 \text{ TeV}$
- First two generation squarks: $\sim 800 \text{ GeV}$
- Stops: $\sim 700 \text{ GeV}$
- Electroweakinos: $\sim 400 - 700 \text{ GeV}$.

... in the most extreme cases only!

Limits much weaker in certain scenarios:
Compressed models,...

Model	$\epsilon, \mu, \tau, \gamma$	Jets	$E_{\text{min}}^{\text{jet}}$	$[\mathcal{L} \cdot dt(\text{fb}^{-1})]$	Mass limit	Reference

WIMP interaction (DS, Disc χ)	0	mono-jet	Yes	10.5	100 GeV	$m(\tilde{t}) \geq 80 \text{ GeV}$, $m(\tilde{t}^*) \geq 80 \text{ GeV}$	ATLAS-COMP-2012-147	

*Only a selection of the available mass limits on new states or phenomena is shown. All limits quoted are observed minus 1 σ theoretical signal cross section uncertainty.

Expectations for Run 2 and the HL-LHC

Extrapolations to 13/14 TeV

→ Expect to be sensitive to yet unexplored SUSY territory with few fb^{-1} !

HL-LHC

[ATL-PHYS-PUB-2014-010]

→ Discovery reach up to 2.5-3 TeV

Looking forward to Run 2!

Backup

ATLAS detector

Also exploit the longitudinal information of an event.

- Both particles are pair-produced, the initial heavy particles are assumed here to have the same masses or to be at the same mass scale
- Both decay chains are symmetric if going into the frame where the initial heavy particle is at rest
- Can group all visible particles of one decay chain into a mega-jet; both mega-jets should have the same energy

Variables to benefit from this configuration:

- **Characteristic mass of the event:**

$$M'_R = \sqrt{(j_{1,E} + j_{2,E})^2 - (j_{1,L} + j_{2,L})^2}$$

(E : energy, L : longitudinal component, j_1 and j_2 : four-vectors of the two mega-jets)

- **Transverse information of the event:**

$$M_T^R = \sqrt{\frac{|\vec{E}_T^{\text{miss}}|(|\vec{j}_{1,T}| + |\vec{j}_{2,T}|) + \vec{E}_T^{\text{miss}} \cdot (\vec{j}_{1,T} + \vec{j}_{2,T})}{2}}$$

- **Razor:**

$$R = \frac{M_T^R}{M'_R}$$

- Effective mass: $m_{\text{eff}}^{\text{incl}} = \sum p_{\text{T}}^{\text{jet}} + p_{\text{T}}^{\text{lepton}} + E_{\text{T}}^{\text{miss}}$

- Transverse mass:

$$m_{\text{T}} = \sqrt{2 \cdot E_{\text{T}}^{\text{miss}} \cdot p_{\text{T}}(\text{lepton}) \cdot (1 - \cos \Delta\phi(\vec{E}_{\text{T}}^{\text{miss}}, \vec{p}_{\text{T}}(\text{lepton})))}$$

- Cotransverse mass: $m_{\text{CT}} = \sqrt{(E_{\text{T}}^{b_1} + E_{\text{T}}^{b_2})^2 - (\vec{p}_{\text{T}}^{b_1} - \vec{p}_{\text{T}}^{b_2})^2}$

- $E_{\text{T}}^{\text{miss,rel}} = \begin{cases} E_{\text{T}}^{\text{miss}} & \Delta\phi > \pi/2 \\ E_{\text{T}}^{\text{miss}} \sin \Delta\phi & \Delta\phi < \pi/2 \end{cases}$

Gauge Mediated SUSY Breaking

→ Further possibility to break SUSY.

GMSB:

- Breaking of SUSY via messenger interactions.
- SM flavor symmetry naturally protected.
- Gravitino lightest supersymmetric particle.
- Detector signature determined by nature of NLSP (can be $\tilde{\chi}_1^0$, $\tilde{\tau}$, \tilde{l}_R)
- NLSP decays to LSP (\tilde{G}) and the SM superpartner of the NLSP.
- Parameters for minimal GMSB: Λ (SUSY breaking scale), N_5 (# messenger fields), $\tan \beta$, sign of μ , C_{grav} (G mass scale factor), M_{mes} .

General Gauge Mediation (GGM):

- No specific SUSY mass hierarchy for (un)colored states → any MSSM sparticle can be the NLSP.
- Nature of neutralino depends on M_1 , M_2 , μ and $\tan \beta$.

Natural Gauge Mediation:

- All sparticles not related to fine-tuning of Higgs sector decoupled.
- Stop and gluino only light colored sparticles.

Selected results in GGM models

4-leptons

[Phys.Rev.D. 90, 052001 (2014)]

The RPV 4-lepton analysis also interprets in GGM models.

Diphoton+ E_T^{miss}

[ATLAS-CONF-2014-001]

- Analysis specifically designed for GGM models.
- Event selection based on high E_T^{miss} , m_{eff} or H_T , and by cutting on minimal angles ϕ between photons/jets and E_T^{miss} .

Events with only a mono-photon appear in various scenarios:

- Large extra spatial dimensions.
- Direct production of weakly interacting massive particles through interaction with quarks via a heavy mediator.
- Very compressed SUSY scenarios, e.g. with pair-wise produced squarks and direct decay to LSPs. (Masses of squarks and LSPs then very close.)

Interpretations
