$b \to s$ transitions workshop
6-10-2015 | Marseille

Outline

1. $g_\mu - 2$ and $b \to s\mu\mu$ anomalies ⟹ DM
2. a toy model for muon-philic DM
3. DM relic density
4. collider signatures

First signs of DM in B physics?*

**non-gravitational*

$B \to (K, K^*, \phi) + \mu^+\mu^-$ anomalies

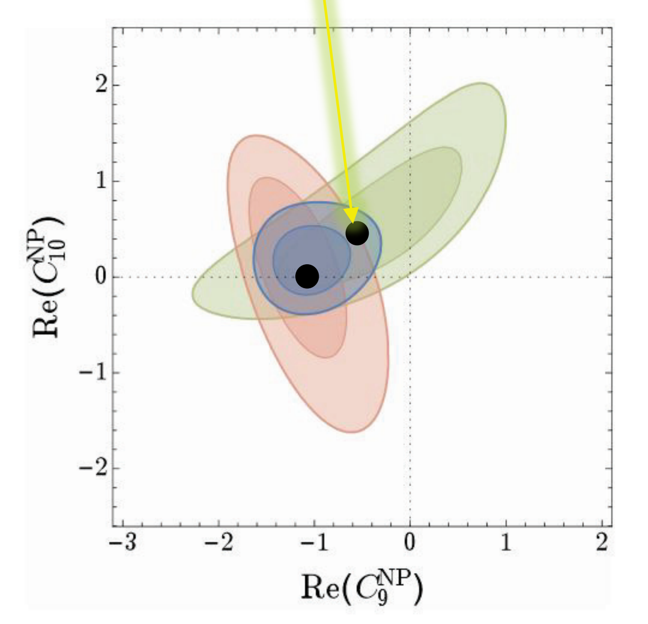
Decay	obs.	q^2 bin	SM pred.	measurement		pull
$\bar{B}^0 \to \bar{K}^{*0}\mu^+\mu^-$	F_L	$[2, 4.3]$	0.81 ± 0.02	0.26 ± 0.19	ATLAS	$+2.9$
$\bar{B}^0 \to \bar{K}^{*0}\mu^+\mu^-$	F_L	$[4, 6]$	0.74 ± 0.04	0.61 ± 0.06	LHCb	$+1.9$
$\bar{B}^0 \to \bar{K}^{*0}\mu^+\mu^-$	S_5	$[4, 6]$	-0.33 ± 0.03	-0.15 ± 0.08	LHCb	-2.2
$\bar{B}^0 \to \bar{K}^{*0}\mu^+\mu^-$	P_5'	$[1.1, 6]$	-0.44 ± 0.08	-0.05 ± 0.11	LHCb	-2.9
$\bar{B}^0 \to \bar{K}^{*0}\mu^+\mu^-$	P_5'	$[4, 6]$	-0.77 ± 0.06	-0.30 ± 0.16	LHCb	-2.8
$B^- \to K^{*-}\mu^+\mu^-$	$10^7\ \frac{dBR}{dq^2}$	$[4, 6]$	0.54 ± 0.08	0.26 ± 0.10	LHCb	$+2.1$
$\bar{B}^0 \to \bar{K}^0\mu^+\mu^-$	$10^8\ \frac{dBR}{dq^2}$	$[0.1, 2]$	2.71 ± 0.50	1.26 ± 0.56	LHCb	$+1.9$
$\bar{B}^0 \to \bar{K}^0\mu^+\mu^-$	$10^8\ \frac{dBR}{dq^2}$	$[16, 23]$	0.93 ± 0.12	0.37 ± 0.22	CDF	$+2.2$
$B_s \to \phi\mu^+\mu^-$	$10^7\ \frac{dBR}{dq^2}$	$[1, 6]$	0.48 ± 0.06	0.23 ± 0.05	LHCb	$+3.1$

2 favored simple NP structure:

$C_9 \simeq -1, C_{10} = C'_{9,10} = 0$

or TH favored

$C_{10} = -C_9 \simeq 0.5, C'_{9,10} = 0$



$$\mathcal{H}_{\rm eff}^{\rm NP} = -\frac{\alpha G_F}{2\sqrt{2}\pi} V_{tb} V_{ts}^* \sum_i C_i \mathcal{O}_i + \text{h.c.}$$

$$\mathcal{O}_9^\ell \equiv \bar{b}\gamma_\rho(1-\gamma_5)s\ \bar{\ell}\gamma^\rho\ell$$
$$\mathcal{O}_{10}^\ell \equiv \bar{b}\gamma_\rho(1-\gamma_5)s\ \bar{\ell}\gamma^\rho\gamma_5\ell$$

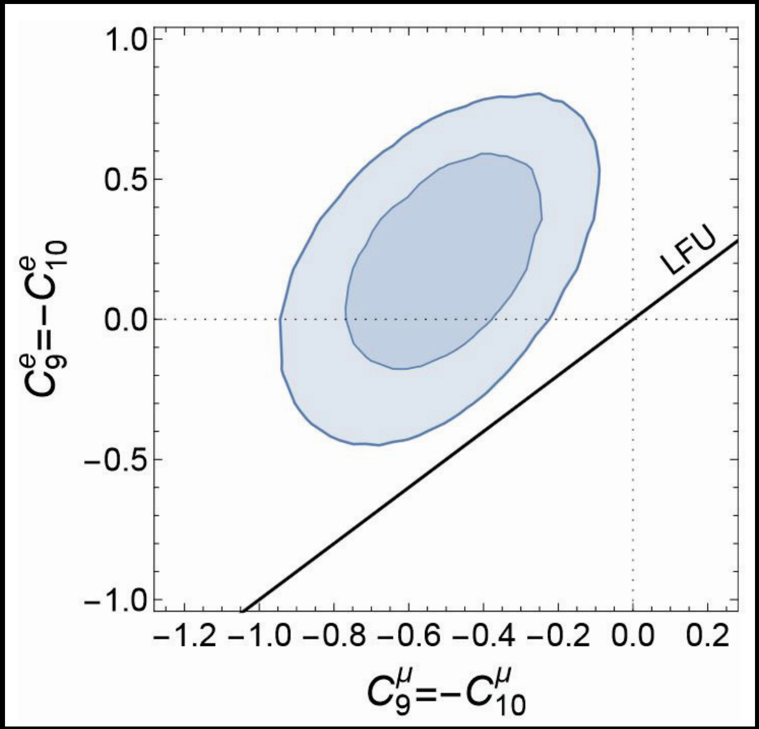
R_K anomaly

Adding electron data, in particular

$$R_K \equiv \frac{\mathrm{BR}(\mathrm{B} \to \mathrm{K}\mu^+\mu^-)_{[1,6]}}{\mathrm{BR}(\mathrm{B} \to \mathrm{K}e^+e^-)_{[1,6]}} = 0.745^{+0.090}_{-0.074} \pm 0.036 \lesssim 1$$

global fits indicate violation of Lepton Flavor Universality

$$C^e_{9,10} \ll C^\mu_{9,10}$$



$g_\mu - 2$ anomaly

Long story with many bounces between TH and EXP,
But current status still anomalous: $\left(a_\mu \equiv \frac{g_\mu - 2}{2}\right)$

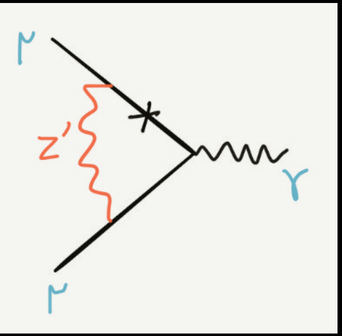
$$\Delta a_\mu \equiv a_\mu^{\rm exp} - a_\mu^{\rm SM} = (287 \pm 80) \times 10^{-11}$$

If discrepancy originates from one-loop new physics,
weak scale/coupling are favored

$$a_\mu^{\rm BSM} \sim \frac{g^2 m_\mu^2}{16\pi^2 M^2} \sim 3 \times 10^{-9} \left(\frac{g}{0.6}\right)^2 \left(\frac{100\,{\rm GeV}}{M}\right)^2$$

A hint for DM

- Tree-level explanations of $b \to s$ typically yields a too small contribution to $g_\mu - 2$:



$$\to a_\mu^{Z'} \sim \mathcal{O}(10^{-11}) \left(\frac{1\,\mathrm{TeV}}{m_{Z'}}\right)^2$$

- If $b \to s$ arises at one-loop, $g_\mu - 2$ in the right ballpark.
- A simple way with a Z' : seclude it from SM, break $\mathrm{U}(1)_X \to Z_2$ ➡ DM candidate

A toy model
for loop-induced Z’
couplings to muons

The simplest toy model

$$\mathcal{L} = \mathcal{L}_{\text{SM}} + \mathcal{L}_{\text{dark}} + \mathcal{L}_{\text{portal}}$$

Dark $\text{U}(1)_X$ field, SM carry no X charge,

Dark sector fields:

		spin	$SU(3)_c$	$SU(2)_L$	$U(1)_Y$	$U(1)_X$
mediators to SM fermions	$L,\ L^c$	$1/2$	$\mathbf{1}$	$\mathbf{2}$	$-1/2$	1
	$Q,\ Q^c$	$1/2$	$\mathbf{3}$	$\mathbf{2}$	$1/6$	-2
U(1) breaking	ϕ	0	$\mathbf{1}$	$\mathbf{1}$	0	2
Dark Matter	χ	0	$\mathbf{1}$	$\mathbf{1}$	0	-1

The simplest toy model

$$\mathcal{L} = \mathcal{L}_{\rm SM} + \mathcal{L}_{\rm dark} + \mathcal{L}_{\rm portal}$$

hypercharge portal *Higgs portal*

$$\mathcal{L}_{\rm portal} = \epsilon B \cdots {}^{\mu\nu} - \lambda_{\chi H}|\chi|^2|H|^2 - \lambda_{\phi H}|\phi|^2|H|^2$$

~closed ~closed

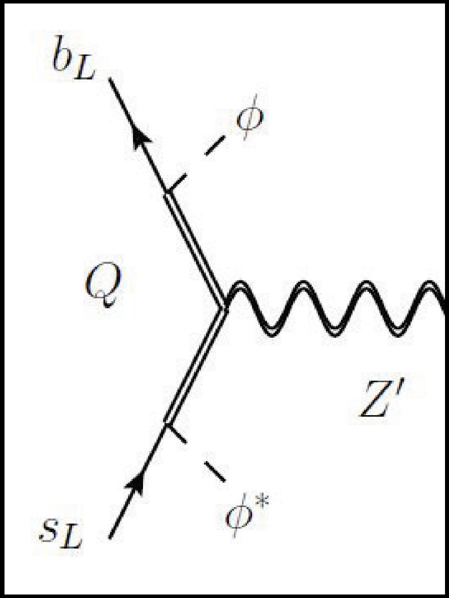
$$-y\,(\bar{l}L)\chi - w\,(\bar{q}Q)\phi + \text{h.c.}$$

'Yukawa' portal *mass mixing = "partial darkness"*

The X charge assignment forbids tree-level $Z'\bar{l}l$ coupling, makes DM leptophilic, explaining direct detection null results

Z' coupling to SM fermions

- Quarks: partial darkness $w(\bar{q}Q)\langle\phi\rangle + \text{h.c.}$



switch on only $\bar{b}_L s_L$ coupling

motivated by LHCb anomalies

(not much changes with also $\bar{s}_L s_L$)

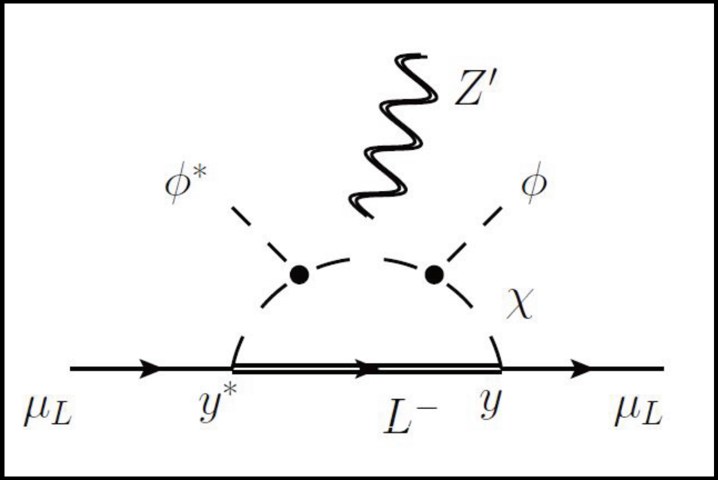
$B-\bar{B}$ mixing constraint*:

$$g_{bs}^L \lesssim 2.4\times 10^{-3}\left(\frac{m_{Z'}/g_X}{300\,\text{GeV}}\right)$$

*NP<0.1SM

Z' coupling to SM fermions

- Leptons: $(\bar{l}L)\phi$ not allowed ⟶ one-loop



$$g^L_{\mu\mu} = \frac{|y|^2}{32\pi^2} F(\tau, \delta)$$

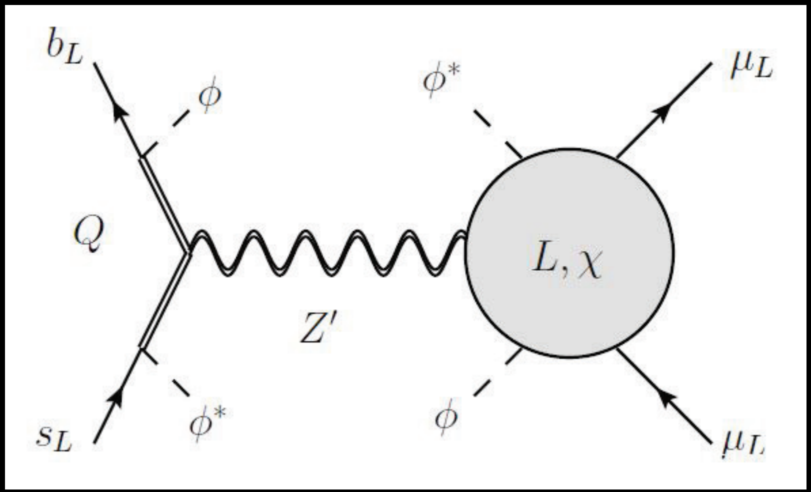
$$\tau \equiv \frac{m_L^2}{m_\chi^2}\,,\ \delta \equiv \frac{m_{\chi'}^2}{m_\chi^2} - 1$$

For $\delta \to 0$, $g^L_{\mu\mu}(q^2 = 0) = 0$, $\langle\phi\rangle$-insertion needed

$(\phi^* D_\rho \phi \bar{\mu}_L \gamma^\rho \mu_L)$

⟹ significant DM-DM' splitting

Explaining $b \to s\mu\mu$ anomalies



$$C^{\mu}_{10,-9} = \frac{g_X^2 \Lambda_{\rm SM}^2}{m_{Z'}^2} \frac{|V_{ts}^* V_{tb}|}{V_{ts}^* V_{tb}} g^L_{bs} g^L_{\mu\mu}$$

$$\Lambda_{\rm SM} \equiv [2\sqrt{2}\pi/(\alpha G_F |V_{ts}^* V_{tb}|)]^{1/2} \simeq 50 \text{ TeV}$$

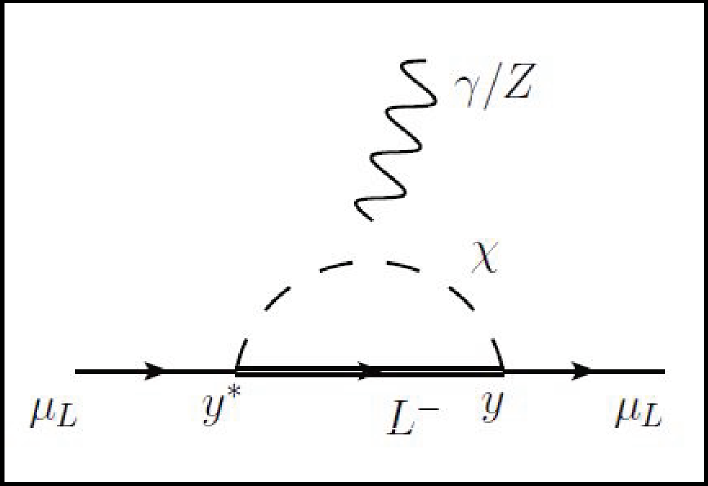
Under $B - \bar{B}$ constraint, explaining LHCb requires:

$$g^L_{\mu\mu} \gtrsim 0.03 \left(\frac{m_{Z'}/g_X}{300\,\text{GeV}} \right)$$

In turns, one needs: $y \gg 1, \ \delta \gg 1$, a light Z' and $\tau \simeq [1, \delta]$

Accomodating Δa_μ sets DM mass

$g_\mu - 2$ further constrains the parameter space:



$$\Delta a_\mu = \frac{|y|^2 m_\mu^2}{32\pi^2 m_\chi^2} G(\tau, \delta)$$

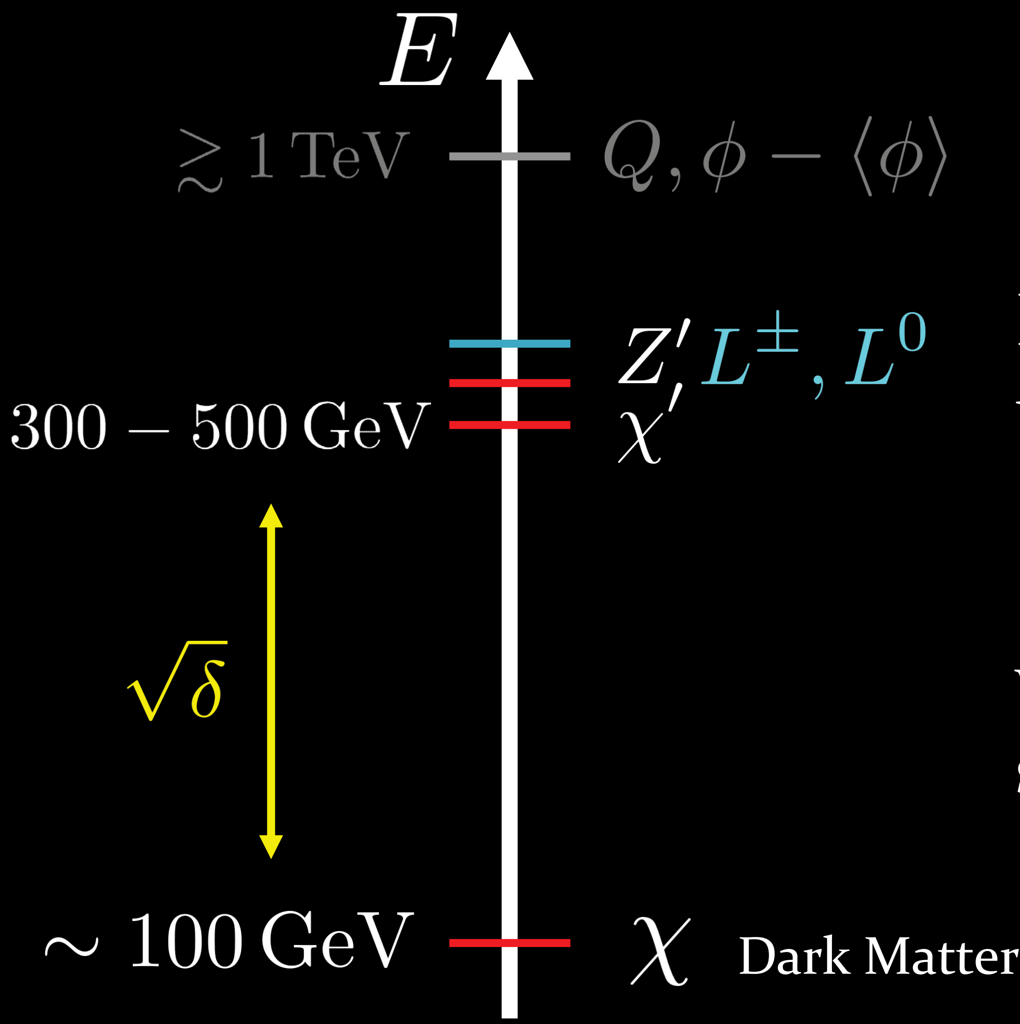
$$\tau \equiv \frac{m_L^2}{m_\chi^2}, \; \delta \equiv \frac{m_{\chi'}^2}{m_\chi^2} - 1$$

2 limiting scenarios:

$$\tau \simeq 1 \longrightarrow m_\chi \simeq 30|y|(1 + 2/\delta)\ \text{GeV}$$

$$\tau \simeq \delta \longrightarrow m_\chi \simeq 55 \frac{|y|}{\sqrt{\delta}}\ \text{GeV}$$

So, muon anomalies favors:



Large δ needs tuning in the dark scalar potential:

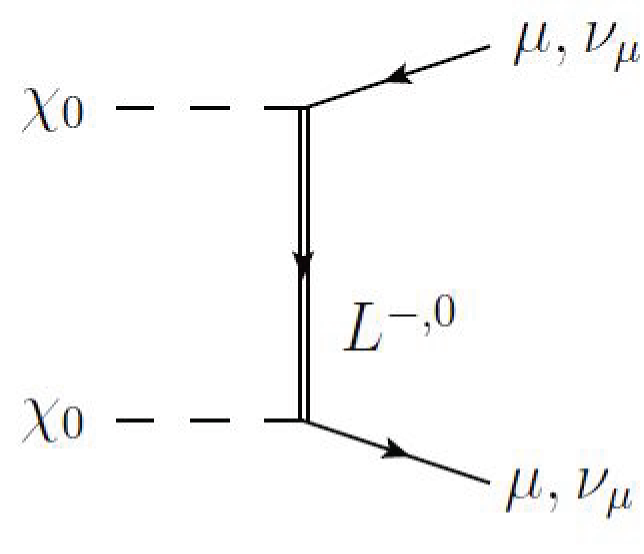
$$\delta \sim \mathcal{O}(10)$$

which guarantees DM is scalar (see relic later)

DM relic prediction from muon anomalies

Scalar DM annihilation

- At freeze-out dominant process is d-wave:



$$\langle \sigma v \rangle = \frac{|y|^4 x^{-2}}{2\pi(1+\tau)^4 m_\chi^2}$$

$$\langle v^2 \rangle^{-1} \sim x \equiv \frac{m_\chi}{T} \simeq 25$$

- Thus DM relic also favors large y ,

  for weak scale m_χ

Relic density prediction

- Note that: $\Delta a_\mu \propto \frac{|y|^2}{m_\chi^2}$, $C_{9,-10} \propto |y|^2$

Hence: $\Omega_\chi \sim \int_T \langle \sigma v \rangle^{-1} \propto \Delta a_\mu^{-1} \times C_{9,-10}^{-1}$
and

$$\Omega_\chi h^2 \simeq 0.01 R(\tau,\delta) \times \left(\frac{x}{25}\right)^3 \left(\frac{100\,\mathrm{GeV}}{m_{Z'}/g_X}\right)$$

with

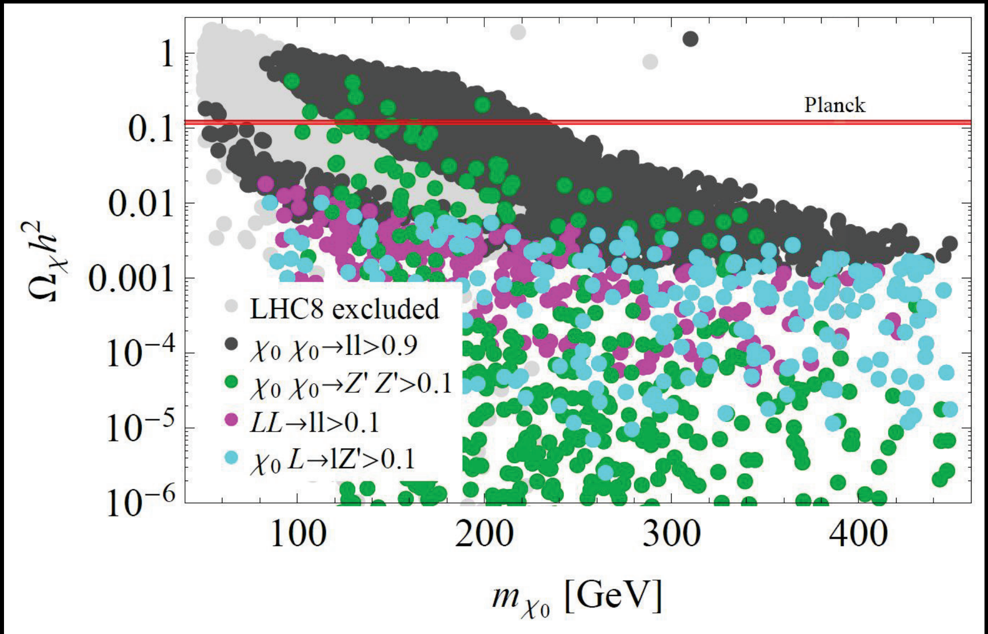
$$R(\tau,\delta) \equiv F(\tau,\delta) G(\tau,\delta)(1+\tau)^4 \sim \mathcal{O}(10)$$

Muon anomalies yields DM relic
in the right ballpark!

$\Omega_{\mathrm{DM}}^{\mathrm{CMB}} h^2 \simeq 0.11$

Is Relic prediction robust?

Sniffing around the parameter space with micrOMEGAs, under the anomalies constraints ⟶



Relatively robust, except in peculiar corners with:

1) strong coannihilation $m_L \gtrsim m_\chi$

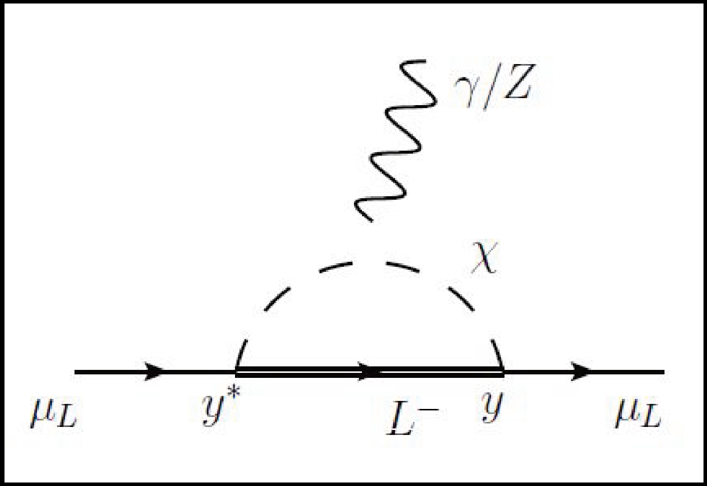
and/or

2) open Z' channel $m_{Z'} < m_\chi$

Tests at colliders and DM detection experiments

EW Precision test

- The $Z\bar{\mu}\mu$ coupling is shifted at one-loop:



corrects R_μ and $A_{\rm FB}^\mu$

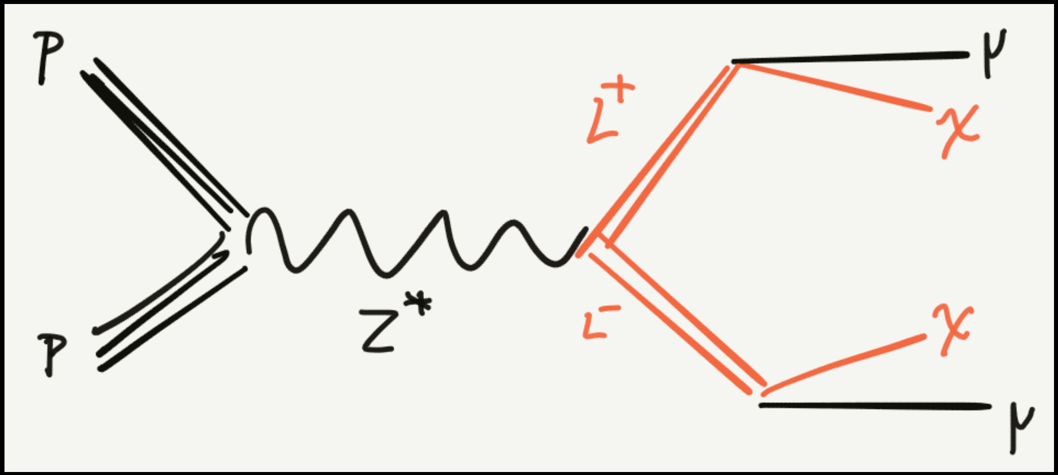
$$\frac{\delta g^Z_{\mu_L}}{g_{\rm SM}} \simeq (1-3)\times 10^{-3}$$

- Mild tension with LEP data: $\delta g^Z_{\mu_L}/g_{\rm SM} \lesssim 10^{-3}$

- May-be solved in complete model?

Heavy lepton searches at LHC

- $pp \to Z^* \to LL \to \mu\mu + \not{E}_T$



- Recasting SUSY searches for smuons:

$m_L \gtrsim 450\,\mathrm{GeV}$

unless $\tau \simeq 1$

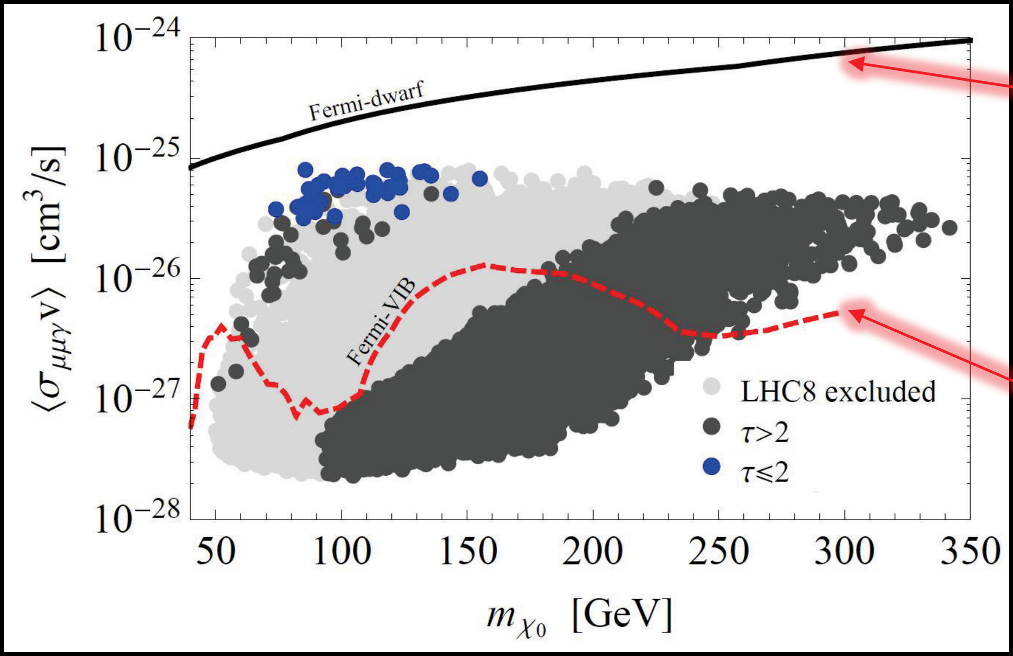
where missing E_T is missing

Dimuons from resonnant Z'

- LHC bound on Z' with Z-like fermions couplings are rather strong: $m_{Z'_{\mathrm{SSM}}} \gtrsim 3\,\mathrm{TeV}$
- Here Z' produced through $\bar{b}s + \bar{s}b$ with $\mathrm{BR}(Z' \to \mu\mu) \sim \mathcal{O}(50\%)$, so one finds $\sigma(pp \to Z' \to \mu\mu) \sim \mathcal{O}(\mathrm{fb})$ for $m_{Z'} = 300\,\mathrm{GeV}$
- LHC8 sensitivity $\sim 10\,\mathrm{fb}$, it's not clear the low mass region will improve at 13-14TeV…

Indirect DM detection

- Today $v_{\mathrm{halo}} \sim 10^{-3}$: 2 body ann. suppressed
- Dominant process $= \chi\chi \to \mu\mu\gamma$ (s-wave)
- Could give gamma-ray signals at FERMI:



continuum in nearby dwarves

line search from galactic center

Wrapping up

Conclusions

- Loop-induced Z' couplings to SM allow to simultaneously address $g_\mu - 2$ and $b \to s\mu\mu$
- The symmetry forbidding tree-level couplings typically breaks to a discrete subgroup yielding (leptophilic) DM!
- The same interaction controlling the muon anomalies drives DM annihilation in the early Universe, giving $\Omega_\chi \simeq 0.1$!

Beauty in the sky with muons

Direct detection below ν-bkg
