Summary : LHC di-photon searches

Search for di-photon resonances in the mass range from 150 to 850 GeV in pp collisions at

$\sqrt{s} = 8 \text{ TeV}$

The CMS Collaboration (1506.02301)

Abstract

Results are presented of a search for heavy particles decaying into two photons. The analysis is based on a 19.7 fb^{-1} sample of proton-proton collisions at $\sqrt{s} = 8 \text{ TeV}$ collected with the CMS detector at the CERN LHC. The diphoton mass spectrum from 150 to 850 GeV is used to search for an excess of events over the background. The search is extended to new resonances with natural widths of up to 10% of the mass value. No evidence for new particle production is observed and limits at 95% confidence level on the production cross section times branching fraction to diphotons are determined. These limits are interpreted in terms of two-Higgs-doublet model parameters.

Search for di-photon resonances in the mass range from 150 to 850 GeV in pp collisions at

$\sqrt{s} = 8 \text{ TeV}$

The CMS Collaboration (1506.02301)

Figure 7: Exclusion limit at 95% CL on the cross section times branching fraction of a new, spin-0 resonance decaying into two photons as a function of the resonance mass hypothesis, combining the four classes of events. The results for a narrow resonance hypothesis ($\Gamma_X = 0.1 \text{ GeV}$) (left) and for a wide resonance hypothesis ($\Gamma_X = 0.1 m_X$) (right) are shown.

Search for High-Mass Diphoton Resonances in pp Collisions at $\sqrt{s} = 8$ TeV with the CMS Detector

The CMS Collaboration

Abstract

A search for high-mass diphoton resonances is performed in proton-proton collisions at $\sqrt{s} = 8$ TeV, with data corresponding to an integrated luminosity of 19.5 fb^{-1} , collected by the CMS detector at the CERN Large Hadron Collider. Such a diphoton resonance could be a signature of an excited state of the graviton in the Randall-Sundrum scenario with a warped extra dimension of space. The background to this signal comes from real standard model diphoton production, and from photon+jet or dijet processes where one or two jets produce a fake photon signature in the detector. The observed diphoton mass distribution is compared to the background prediction, and no significant excess of events over the background is found. 95% confidence level limits are set in the parameter space of the Randall-Sundrum model: masses below 1450 – 2780 GeV are excluded for the first excited state of the Randall-Sundrum graviton, for values of the coupling parameter k/M_{Pl} in the range $0.01 \leq k/M_{\text{Pl}} \leq 0.1$.

Search for Scalar Diphoton Resonances in the Mass Range 65–600 GeV with the ATLAS Detector in pp Collision Data at $\sqrt{s} = 8$ TeV

ATLAS Collaboration

A search for scalar particles decaying via narrow resonances into two photons in the mass range 65–600 GeV is performed using 20.3 fb^{-1} of $\sqrt{s} = 8$ TeV pp collision data collected with the ATLAS detector at the Large Hadron Collider. The recently discovered Higgs boson is treated as a background. No significant evidence for an additional signal is observed. The results are presented as limits at the 95% confidence level on the production cross-section of a scalar boson times branching ratio into two photons, in a fiducial volume where the reconstruction efficiency is approximately independent of the event topology. The upper limits set extend over a considerably wider mass range than previous searches.

Search for high-mass diphoton resonances in pp collisions at $\sqrt{s} = 8$ TeV with the ATLAS detector

The ATLAS Collaboration. [[arXiv:1504.05511](#)]

Abstract

This article describes a search for high-mass resonances decaying to a pair of photons using a sample of 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV recorded with the ATLAS detector at the Large Hadron Collider. The data are found to be in agreement with the Standard Model prediction, and limits are reported in the framework of the Randall-Sundrum model. This theory leads to the prediction of graviton states, the lightest of which could be observed at the Large Hadron Collider. A lower limit of 2.66 (1.41) TeV at 95% confidence level is set on the mass of the lightest graviton for couplings of $k/\overline{M}_{\text{Pl}} = 0.1$ (0.01).

Search for high-mass diphoton resonances in pp collisions at $\sqrt{s} = 8$ TeV with the ATLAS detector

The ATLAS Collaboration • [arXiv:1504.05511]

Figure 4: Expected and observed upper limits on $\sigma \times BR(G^* \rightarrow \gamma\gamma)$ expressed at 95% CL, as a function of the graviton mass. At large m_{G^*} , the -1σ and -2σ variations of the expected limit tend to be particularly close to the expected limit. This is expected, since signals with high m_{G^*} would appear in regions of $m_{\gamma\gamma}$ where the background expectation is small and the Poissonian fluctuations around the mean expected background are highly asymmetric. The curves show the RS model prediction for given values of $k/\overline{M}_{Pl}$ as a function of m_{G^*} . They are obtained using the PYTHIA generator plus a K -factor to account for NLO corrections (see text). The thickness of the theory curve for $k/\overline{M}_{Pl} = 0.1$ illustrates the PDF uncertainties expressed at 90% CL.

Summary : LHC di-photon searches

Search for new physics in high mass diphoton events in proton-proton collisions at

$\sqrt{s} = 13 \text{ TeV}$

The CMS Collaboration (CMS PAS EXO-15-004)

Abstract

We report on a search for new physics using high mass diphoton events. The search employs 2.6 fb^{-1} of pp collision data collected by the CMS experiment in 2015 at a center-of-mass energy of 13 TeV and it is aimed at extradimensional models leading to resonant production of two photons. Limits on the production cross section of Randall-Sundrum gravitons decaying to two photons are obtained in the range 500-4500 GeV.

Search for resonances decaying to photon pairs in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13 \text{ TeV}$ with the ATLAS detector

The ATLAS Collaboration

Abstract

This note describes a search for new resonances decaying to two photons, with invariant mass larger than 200 GeV. The search is optimized for scalars such as those expected, for example, in models with an extended Higgs sector. The dataset consists of 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13 \text{ TeV}$ recorded with the ATLAS detector at the Large Hadron Collider. The data are consistent with the expected background in most of the mass range. The most significant deviation in the observed diphoton invariant mass spectrum is found around 750 GeV, with a global significance of about 2 standard deviations. A limit is reported on the fiducial production cross section of a narrow scalar boson times its decay branching ratio into two photons, for masses ranging from 200 GeV to 1.7 TeV.

Search for resonances decaying to photon pairs in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13 \text{ TeV}$ with the ATLAS detector

cross-section scales like Parton luminosities

gg s-channel = 4.7

qq s-channel = 2.7

Compatibility 8 TeV $\leftrightarrow$ 13 TeV (gg hypothesis): 1.2σ

Compatibility 8 TeV $\leftrightarrow$ 13 TeV (qq hypothesis): 2.1σ

Spin 2

8 TeV data: no excess in the region of interest

Compatibility 8 TeV $\leftrightarrow$ 13 TeV (gg hypothesis): 2.7σ

Compatibility 8 TeV $\leftrightarrow$ 13 TeV (qq hypothesis): 3.6σ

Standard RS type model can not explain, no peak in di-lepton
distributions

Width

1601.04751(M R. Buckley)

1. Explaining the anomaly through a spin-0 resonance is preferred over a spin-2 mediator, though this preference is less than 1σ in most cases.
2. The cross sections needed for the ATLAS13 and CMS13 data sets are incompatible at the one sigma level, though they agree in mass.
3. When considering only the 13 TeV data, the CMS13 data does not share the ATLAS13 preference for a 45 GeV width. I find that the “wide” interpretation of the resonance has a statistical significance in the COMBO13 data set which is approximately 0.5σ less likely than the “narrow” interpretation.

Reducible vs irreducible backgrounds

Mostly irreducible

diphoton bkg estimation and fitting

Background fitting function

$$\text{ATLAS8/13} : f(m_{\gamma\gamma}; a_0, b) = \left(1 - \left(\frac{m_{\gamma\gamma}}{\sqrt{s}} \right)^{1/3} \right)^b \left(\frac{m_{\gamma\gamma}}{\sqrt{s}} \right)^{a_0},$$

$$\text{CMS13} : f(m_{\gamma\gamma}; a, b) = m_{\gamma\gamma}^{a+b \log m_{\gamma\gamma}},$$

$$\text{CMS8} : f(m_{\gamma\gamma}; p_1, p_2) = e^{-p_1 m_{\gamma\gamma}} m_{\gamma\gamma}^{-p_2}.$$

Figure 1: Invariant mass distribution of the selected diphoton events. Residual number of events with fit result are shown in the bottom pane. The first two bins in the lower pane are outside the vertical plot

diphoton bkg estimation: Theory vs data

Figure 7. The invariant mass of the photon pair $m_{\gamma\gamma}$ at NLO and NNLO, compared with the CMS data from ref. [15]. The pure NNLO prediction is shown in the left panel, while the result that also includes $gg n_F$ contributions that enter at N³LO is depicted in the right panel. The lower panels present the ratio of the data and NNLO scale variations to the NNLO theory prediction obtained with the central scale.

diphoton bkg estimation: Theory vs data

Figure 11. The rate-normalized shapes of the $m_{\gamma\gamma}$ distribution from the ATLAS collaboration and the MCFM NNLO prediction for $\mu = m_{\gamma\gamma}$. The lower panel indicates the ratio of the data to the NNLO prediction.

Conclusion : We found that the shape of our NNLO prediction does a good job of describing the experimental data, and simultaneously has a good agreement with the fitting function used by the ATLAS collaboration. We therefore do not expect further data at high energies to dramatically alter the form of the fit used by the collaboration. Furthermore, we do not believe that the excess is due to the use of a fitting function that underestimates the prediction of the SM at high invariant masses.

		19 (IM7) [30]	15	5	1.5	0.5

Table 1. Extrapolations of experimental limits relevant for the 750 GeV diphoton. The models are constrained by the strongest of the 8 TeV and 13 TeV observed limits. The inclusive regions SR7 (for the mono-jet (MET+ j) 8 TeV search) and IM5 (for the corresponding 13 TeV results) are characterized by $E_T^{\text{miss}} > 500$ GeV. The inclusive region IM7 for the 13 TeV search is defined by $E_T^{\text{miss}} > 700$ GeV. For the ZZ and $t\bar{t}$ searches the expected limit at 3.2 fb^{-1} is extrapolated from the 8 TeV expected bound (see text).

The “vanilla” model (where the scalar resonance is coupled only to SM gauge bosons with dimension five operators) : almost completely covered by associated signals in di-bosons with 3000 ifb.

S is a portal to a dark sector: mono-jet searches are able to corner the model with as little as 30 ifb

scalar resonance couples to SM quarks: the signature in the $t\bar{t}$ final state could provide a handle on distinguishing such scenarios from the “vanilla” model. However, in order for the signal in $t\bar{t}$ to be accessible, sizeable couplings of quarks to S are required, as well as integrated luminosity of at least 300 ifb

diphoton bkg estimation and fitting

1601.03153(J H. Davis, M. Fairbairn, J Heal and P. Tunney)

FIG. 1. Comparison of empirical functions for the continuum diphoton background which best fit to the data. We consider the fit function used by the ATLAS collaboration with and without the $\log x$ exponent, and also our own empirical function.

Background function	Free width	NWA
$y = (1 - x^{1/3})^b x^{a_0}$	3.9σ	3.6σ
$y = (1 - x^{1/3})^b x^{a_0+a_1 \log x}$	2.9σ	2.6σ
$y = (1 - x^{1/3})^b (x^{c_0} + x^{a_0+a_1 \log x})$	2.0σ	2.0σ

TABLE I. Local significance for a resonance-like signal at $m_{\gamma\gamma} \sim 750$ GeV under different assumptions for the functional dependence of the smooth background. The first function is the one used by ATLAS in their analysis. We either allow the width of the resonance to vary freely, or keep it fixed in the case of the Narrow Width Approximation (NWA).

Background function	NWA	Free-width
Fixed normalisation		
$k = 0$	4.2σ	4.9σ
$k = 1$	3.4σ	3.7σ
$k = 2$	3.4σ	3.7σ
Free normalisation		
$k = 0^\dagger$	3.4σ	3.6σ
$k = 1$	3.5σ	3.8σ
$k = 2$	3.4σ	3.6σ
ATLAS reported	3.6σ	3.9σ

TABLE III. Estimated local significance of the ATLAS 750 GeV diphoton excess obtained in this work using each of the background functions described in Eq. [2], assuming a freely varying resonance width (free-width) and under the narrow width approximation (NWA). The background function used by the ATLAS collaboration in Ref. [1] is marked with a dagger. For comparison, we also give the local significance reported by the ATLAS collaboration.

It is of course necessary to point out that the significances we report are only estimates and care must be taken when comparing with the official ATLAS analysis. In particular, the results reported by ATLAS use the full unbinned data set, while we consider here only binned data. Furthermore, this data was obtained by digitising the results released in Ref. [1]. However, we have investigated the possible impact of digitisation error on our analysis. In order to do this, we added random noise to the first 10 bins in $m_{\gamma\gamma}$ (distributed uniformly between -3% and $+3\%$ of the number of events in each bin) in order to simulate digitisation errors.³ Ten such ‘randomised’ datasets were generated and the peak significance for each was calculated assuming the $k = 0$, free- $\mathcal{N}$ background. The resulting local significances were in the range:

$$\begin{aligned} \text{NWA:} & \quad 3.3\sigma\text{--}3.5\sigma \\ \text{Free-width:} & \quad 3.5\sigma\text{--}3.8\sigma. \end{aligned} \tag{6}$$

These tests indicate that digitisation could have induced an error of order 0.2σ in the analysis, and may also explain some of the discrepancy between our results and those reported by ATLAS.
