**Towards the European Coordination of the CMB programme  
Villa Finaly, Firenze, 6th -8th Septemeber, 2017**

<https://indico.in2p3.fr/event/14661/>

# Stratospheric Balloons:

- Near-space carriers able to:
  - Reach 40 km (3 mbar)
  - Stay there for up to 40 days
  - Lift heavy (2 tons) large payloads (larger than what we can reasonably fly on satellites)
  - Cost roughly 1/100 of a satellite mission
  - Allow for recovery and reflly of the payload
- Important for the CMB community:
  - **To carry out sensitive observations at high frequency, high resolution, and at the largest angular scales**
  - To qualify instrumentation in preparation of satellites
  - To educate young experimentalists !

# Photon noise from the local environment for CMB observations

# Future balloon borne CMB experiments

## Worked Sensitivity Example: **Ground-based**

# Future balloon borne CMB experiments

## Worked Sensitivity Example

- In absolute terms, a large array of photon-noise limited detectors on a ultra-long-duration balloon is able to reach cosmic variance limits at all interesting angular scales.
- The comparison to the theoretical sensitivity of ground-based experiments is interesting because defines the frequency range where the balloon advantage is larger.
- In the absence of atmospheric turbulence:
  - one day of integration on a balloon equals:
    - 12 days of operation on the ground at 220 GHz
    - 34 days of operation on the ground at 270 GHz
    - 198 days of operation on the ground at 340 GHz
    - 1390 days of operation on the ground at 480 GHz
  - At these high frequencies, the advantage of a balloon mission is going to improve if atmospheric turbulence is taken into account.

# Future balloon borne CMB experiments

## Atmospheric Effects: absolute brightness

# Long Duration Ballooning

## Flight Options

- Antarctic Long Duration Balloon (LDB) : 10 – 30 days / 3 tons
- Wanaka Super Pressure Balloon (SPB) : 30 – 100 days / 1 ton
- Polar Night Flights : ~ 10 days
- Conventional Flight (Ft. Sumner, Palestine, Timmons) : 1 day

## Flight Parameters

- 33-37 km altitude
- 1 km altitude stability (200 m for SPB)
- Annual flight windows
  - January (LDB, Svalbard), April (SPB, Wanaka), June (Palestine), September (Ft. Sumner)

Great progress with super-pressure balloons: COSI payload flown by CSBF in may 2016 for 47 days at altitudes between 33 km and 21 km, with a with a 0.5Mm<sup>3</sup> SPB

<https://blogs.nasa.gov/superpressureballoon/>

# Polar Night Flights

# Stratospheric Balloons:

## Disadvantages:

- Stringent limits on mass, power
- Complexity of automation
- Insane integration schedule
- Narrow, and scarce, flight windows
- Risky recovery

# CMB-related science from balloons

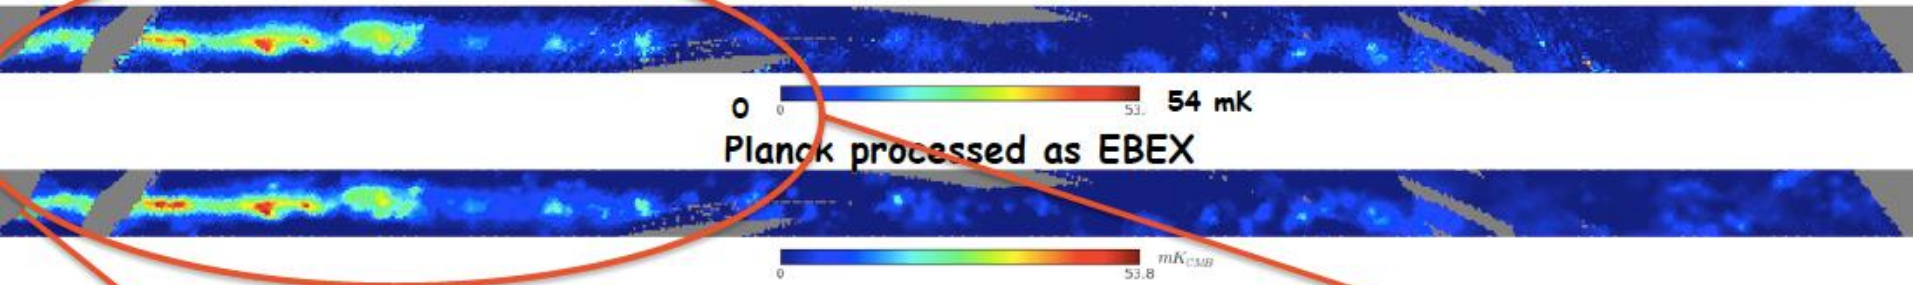

(with large advantage wrt ground-based experiments)

- Dust-cleaned polarization & Dust-cleaned inflationary and lensing B-modes
- CMB Polarization at very large angular scales
- Spectral measurements of the SZ
- Spectral measurements of CIB anisotropy
- Precision measurements of CMB spectrum (at selected frequencies)

ORIGINAL ARTICLE

**PILOT: a balloon-borne experiment to  
the polarized FIR emission of dust grain  
in the interstellar medium**

**Table 1** Key characteristics and performance of the *PILOT* instrument in its nominal configuration. The last lines gives the expected  $3\sigma$  performance in the two extreme observing modes corresponding to deep ( $5^\square/\text{hour}$ ) and large ( $150^\square/\text{hour}$ ) surveys respectively, where the  $\square$  symbol stands for square degree. Our estimated polarization sensitivity assumes a dust polarization fraction of 10 %

Primary mirror diameter [mm]	730	
Equivalent focal length [mm]	1800	
Numerical aperture	$F/2.5$	
Detector temperature [mK]	300	
Mapping speed [ $\square/\text{h}$ ]	[5-150]	
FOV [ $^\circ$ ]	$1.0 \times 0.8$	
	SW Band	LW Band
$\lambda_0$ [ $\mu\text{m}$ ]	240	550
$\nu_0$ [GHz]	1250	545
$\Delta\nu/\nu$	0.27	0.31
Tr(dust)	0.025	0.136
beam FWHM [ $'$ ]	1.9	3.29
Number of Detectors	1024	1024
background [pW/pix]	5.7	4.0
$\text{NEP}_{Det}$ [ $W/\sqrt{Hz}$ ]	$2.0 \cdot 10^{-16}$	$2.0 \cdot 10^{-16}$
$\text{NEP}_{Phot}$ [ $W/\sqrt{Hz}$ ]	$9.8 \cdot 10^{-17}$	$6.0 \cdot 10^{-17}$
$\text{NEP}_{Tot}$ [ $W/\sqrt{Hz}$ ]	$2.2 \cdot 10^{-16}$	$2.1 \cdot 10^{-16}$
Sensitivity ( $3\sigma$ in $3.5'$ )		
Intensity [MJy/sr]	[0.98-6.28]	[0.33-2.13]
$A_v$ [mag]	[0.05-0.30]	[0.12-0.75]
$A_v$ polar [mag]	[0.47-2.99]	[1.17-7.48]

# BFORE

# BSIDE

A balloon project to map dust polarization with the accuracy required to search for primordial B-modes down to a tensor-to-scalar ratio  $r = 0.01$

# B-SIDE Requirements

**Table 2 : Main instrumental requirements**

Primary mirror diameter [mm]	700	
Equivalent focal length [mm]	1800	
Detector temperature [mK]	150 mK (goal) & 220 mK (spec)	
Polarisation modulation [Hz]	40 (goal) & 10 (spec)	
Total transmission	40 % (goal) & 20 % (spec)	
	LF band	HF band
Central Frequency [GHz]	450	600
Bandwidth [GHz]	150	200
Number of detectors	1900 (goal) & 980 (spec)	1900 (goal) & 980 (spec)
Fraction of good pixels	250	250
Multiplexing ratio	90 % (goal) & 70 % (spec)	90 % (goal) & 70 % (spec)
Pixel size	From 2.3x2.3 to 3.2x3.2 mm <sup>2</sup>	From 2.3x2.3 to 3.2x3.2 mm <sup>2</sup>
Resolution [arcmin]	5 (goal) & 7 (spec)	5 (goal) & 7 (spec)
Field of View [degrees]	3	3
NEP [ $10^{-17}$ W.s <sup>1/2</sup> ]	13	17
Observing time	72 hours (goal) & 20 hours (spec)	
Observed area	2000 deg <sup>2</sup>	

- ▶ B-SIDE data to be combined with ground-based observations at 95, 150, 220 GHz and Planck 353 GHz
- ▶ We are discussing a joint data analysis with the BICEP/Keck and the Polarbear/Simons array teams

# Bside datasheet

## OPTICS:

- M1 = 0.8 m
- M2 and M3 at 50K
- FoV = 3 deg
- Angular resolution (540 GHz) ~ 3 arc-min

## DETECTORS:

- Baseline (2018):  $493 \times 2 = 986$  KID
- Angular resolution (baseline) ~ **7 arc-min**
- Electronics power consumption < 150 W
- Cryostat cabled for 2000 KID at the beginning
- Angular resolution (2000 KID) ~ 5 arc-min
- Pixels 23 times bigger than PILOT !!
- Roughly 50-100 pW per pixel
- > **Goal NEP of the order of  $2 \cdot 10^{-16}$  W/Hz<sup>0.5</sup>**

## BANDS:

- Baseline: single band 450-630 GHz
- PlanB will be compatible with **two bands**, e.g. Band 1: 450-630 GHz, Band 2: as-you-like
- My choice: Band 1: 450-630GHz, Band 2: 390-540GHz

***NO NEED TO DECIDE NOW !!!***

# LSPE in a nutshell

- The Large-Scale Polarization Explorer is :
  - an instrument to measure the polarization of the Cosmic Microwave Background at large angular scales
  - The SWIPE instrument uses *a spinning stratospheric balloon payload* to avoid atmospheric noise, flying *long-duration, in the polar night*
  - uses a *polarization modulator* to achieve high stability
- Frequency coverage: 40 – 250 GHz (5 channels, 2 instruments: **STRIP** & **SWIPE**)
- Angular resolution:  $1.3^\circ$  FWHM
- Sky coverage: 20-25% of the sky per flight / year
- Combined sensitivity:  $10 \mu\text{K arcmin}$  per flight

STRIP 45	27%	20%
STRIP 30	33%	24%

## STRIP

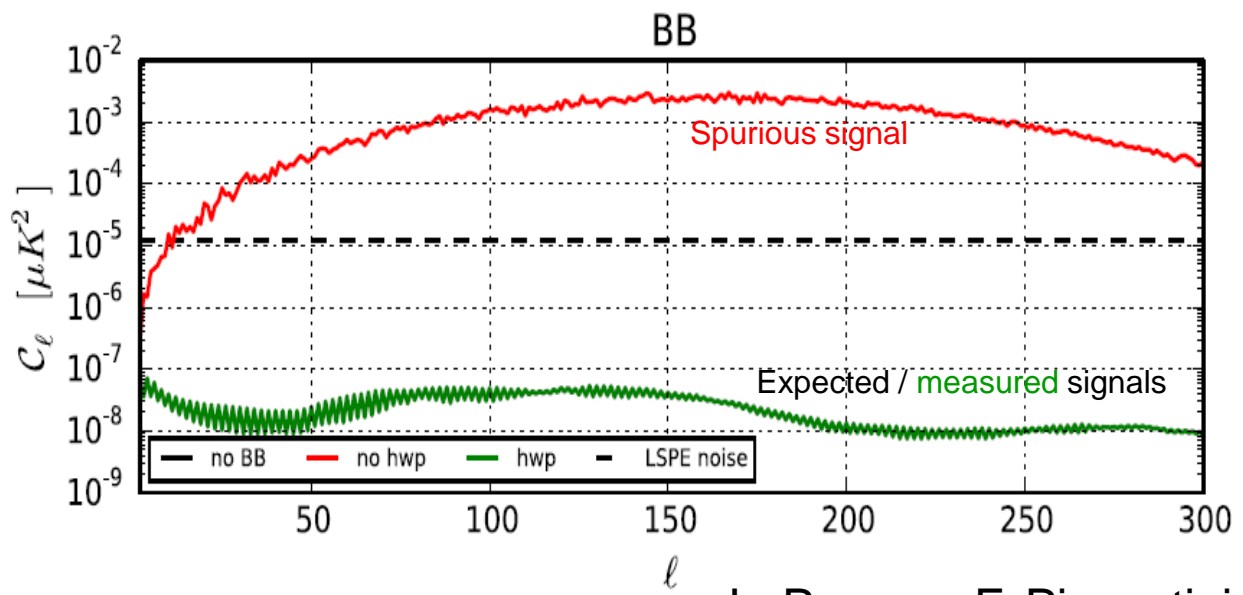

## SWIPE

Source	Culmination (deg)	S/N per sample at 44 GHz	S/N per sample at 90 GHz	S/N per sample at 145 GHz	S/N per sample at 245 GHz
Moon	30	37500	200000	700000	2000000
Crab	34	20	18	23	28
<del>Mars</del>	0	0.30	1.6	5.6	18
Jupiter	27	15	80	275	850
<del>Saturn</del>	-6	1.4	7	24	70
<del>Uranus</del>	16	0.05	0.24	0.8	2.5

Sources culmination angle, and expected S/N per sample. Sampling rate is set at 60 Hz. We assume full Moon, as it is when it is observable by LSPE. The Crab flux is based on the free-free spectrum reported in Macías-Pérez, et al. Ap. J., 711, 417 (2010)

# Performance Forecast

- The presence of the HWP allows to fully exploit the sensitivity of LSPE-SWIPE.
- Realistic simulations to assess systematic effects (mainly beam asymmetries) which become irrelevant if the HWP is used.
- The final sensitivity target for  $r$  is  $< 0.01$

L. Pagano, F. Piacentini

# SWIPE Performance Forecast (1<sup>st</sup> flight)

# Current Status

- LSPE is fully funded by ASI and INFN
- STRIP will operate from the ground (Tenerife) covering the same sky as SWIPE
- STRIP and SWIPE in due course of development, consistent with a 1st launch opportunity from Svalbard (78°N) in Winter 2018/19 for SWIPE and start of data taking in 2018 for STRIP.
- Baseline science expected from (one flight + 1 year) is competitive with current gen B-mode experiments – and contributions to polarized foreground science will provide a great complement the CMB science.

- The OLIMPO experiment is a first attempt at spectroscopic measurements of CMB anisotropy.
- A large balloon-borne telescope with a 4-bands photometric array and a plug-in room temperature spectrometer
- see <http://planck.roma1.infn.it/olimpo> for a collaborators list and full details on the mission
- **Main scientific targets:**
  - **SZ effect in clusters → unbiased estimates of cluster parameters**
  - **Spectrum of CMB anisotropy → anisotropic spectral distortions**

## ABSTRACT

*Context.* The Sunyaev-Zel'dovich (SZ) effect is a powerful tool for studying clusters of galaxies and cosmology. Large mm-wave telescopes are now routinely detecting and mapping the SZ effect in a number of clusters, measure their comptonisation parameter and use them as probes of the large-scale structure and evolution of the universe.

*Aims.* We show that estimates of the physical parameters of clusters (optical depth, plasma temperature, peculiar velocity, non-thermal components etc.) obtained from ground-based multi-band SZ photometry can be significantly biased, owing to the reduced frequency coverage, to the degeneracy between the parameters and to the presence of a number of independent components larger than the number of frequencies measured. We demonstrate that low-resolution spectroscopic measurements of the SZ effect that also cover frequencies  $>270$  GHz are effective in removing the degeneracy.

*Methods.* We used accurate simulations of observations with lines-of-sight through clusters of galaxies with different experimental configurations (4-band photometers, 6-band photometer, multi-range differential spectrometer, full coverage spectrometers) and dif-

A Differential Fourier Transform Spectrometer (DFTS). Similar to COBE-FIRAS but... .. rather than measuring the brightness difference between the sky and an internal blackbody, it measures the **brightness difference between two directions in the sky**

# Olimpo Telescope

- The instrument is based on a double Martin Puplett Interferometer configuration to avoid the loss of half of the signal.

- A wedge mirror splits the sky image in two halves  $I_a$  and  $I_b$ , used as input signals for both inputs of the two FTS's.

- In the FTSs the beam to be analyzed is split in two halves, and a variable optical path difference is introduced.

See Schillaci et al. A&A 565, A125, 2014 for a detailed description of the instrument. The output brightness is

$$I_L = \frac{1}{2}(I_a + I_b) + \frac{1}{2}(I_a - I_b) \cos(\delta)$$

$\delta$  = variable phase shift, introduced by the variable optical path difference.

Only the *difference* between the two input brightnesses is modulated by the variable optical path difference.

## ABSTRACT

*Context.* Precision measurements of the Sunyaev-Zel'dovich effect in clusters of galaxies require excellent rejection of common-mode signals and wide frequency coverage.

*Aims.* We describe an imaging, efficient, differential Fourier transform spectrometer (FTS), optimized for measurements of faint brightness gradients at millimeter wavelengths.

*Methods.* Our instrument is based on a Martin-Puplett interferometer (MPI) configuration. We combined two MPIs working synchronously to use the whole input power. In our implementation the observed sky field is divided into two halves along the meridian, and each half-field corresponds to one of the two input ports of the MPI. In this way, each detector in the FTS focal planes measures the difference in brightness between two sky pixels, symmetrically located with respect to the meridian. Exploiting the high common-mode rejection of the MPI, we can measure low sky brightness gradients over a high isotropic background.

*Results.* The instrument works in the range  $\sim 1\text{--}20\text{ cm}^{-1}$  (30–600 GHz), has a maximum spectral resolution  $1/(2\text{ OPD}) = 0.063\text{ cm}^{-1}$  (1.9 GHz), and an unvignetted throughput of  $2.3\text{ cm}^2\text{sr}$ . It occupies a volume of  $0.7 \times 0.7 \times 0.33\text{ m}^3$  and has a weight of 70 kg. This design can be implemented as a cryogenic unit to be used in space, as well as a room-temperature unit working at the focus of suborbital and ground-based mm-wave telescopes. The first in-flight test of the instrument is with the OLIMPO experiment on a stratospheric balloon; a larger implementation is being prepared for the Sardinia radio telescope.

**Key words.** cosmic background radiation – instrumentation: spectrographs – techniques: spectroscopic – galaxies: clusters: general

The real thing.....  
and measured interferograms

# CMRR

- The differential signal (SZ) is much smaller than the common mode, which is CMB + instrument emissivity (a few %) + residual atmosphere.
- We have measured the common-mode rejection ratio of the FTS using custom temperature-controlled blackbody sources at the two entrance ports of the FTS.
- It turns out that the CMRR of our DFTS is  $< -55\text{dB}$
- This means that the offset is less than the SZ signal in OLIMPO, and will be much less than the SZ signal in a cryogenic/space implementation.

Telescope / primary mirror

DFTS

cryostat / detectors arrays

Main components of OLIMPO integrated on the payload

## Expected performance for OLIMPO (photon noise limited)

### OLIMPO performance: spectrometer configurations, single detector of each array

Band (GHz)	125-175	190-315 (wide)	200-225 (narrow)	330-365	450-500
FWHM (arcmin)	5	3.5	3.5	2	2
Throughput (m <sup>2</sup> sr)	6.3x10 <sup>-6</sup>	3.1x10 <sup>-6</sup>	3.1x10 <sup>-6</sup>	1.0x10 <sup>-6</sup>	1.0x10 <sup>-6</sup>
Background (pW)	36	122	17	20	54
Optical NEP (aW/sqrt(Hz))	200	400	140	170	290
Number of 6 GHz bins in band	9	21	4	5	8
Error per 6 GHz bin (1 sigma, 3 hours) in kJy/sr	3	12	5	16	28

### OLIMPO performance: photometer configurations, single detector of each array

Band (GHz)	125-175	190-315 (wide)	200-225 (narrow)	330-365	450-500
FWHM (arcmin)	5	3.5	3.5	2	2
Throughput (m <sup>2</sup> sr)	6.3x10 <sup>-6</sup>	3.1x10 <sup>-6</sup>	3.1x10 <sup>-6</sup>	1.0x10 <sup>-6</sup>	1.0x10 <sup>-6</sup>
Background (pW)	11	35	5	6	15
Optical NEP (aW/sqrt(Hz))	100	200	70	85	150
NET <sub>CMB</sub> (μK/sqrt(Hz))	80	115	200	780	2500

In a FTS the spectral resolution can be changed (changing the path of the moving mirror). Mind the noise, however: it is proportional to the inverse of the spectral bin-width. In the case of OLIMPO, with a spectrometer at 250K, photon noise is important.

1.8 GHz resolution: About 110 independent spectral bins, within optimized bands.

6 GHz resolution: About 34 independent spectral bins, within the same bands.

OLIMPO calibration  
night (Rome,  
25/4/2014)

$T_{\text{atm}}(350\text{GHz})=0.001$  !!

# The Payload

The OLIMPO payload prepared for a long-duration stratospheric flight, at the airport of Longyearbyen (Svalbard) on July 3rd, 2014.

# Observation Program

- In a circumpolar summer long duration flight (>200h) we plan to observe 40 selected clusters and to perform a blind deep integration on a clean sky region
- We have optimized the observation plan distributing the integration time among the different targets according to their brightness and diurnal elevation.

# Polar flights

- We have flown long duration stratospheric balloons around the North Pole launching from **Longyearbyen** (Svalbard) both in the summer (heavy lift payloads) and in winter (pathfinders) [see Peterzen, S., Masi, S., et al., Mem. S. A. It., 79, 792-798 (2008), and PdB+SM Proc. of the I.A.U., 8, 208-213 (2013) ]
- In this way CMB experiments can access most of the northern sky in a single flight,
  - within a cold and very stable environment
  - Accumulating more than 10 days of integration at float (38 km altitude).

**Top:** Ground path of a flight performed in June 2007. **Bottom left:** Launch of a heavy-lift balloon from the Longyearbyen airport (Svalbard Islands, latitude 78°N).

- OLIMPO will have its first flight in the Arctic (2016?) and the second one from Antarctica (2018 if recovered well)

- The OLIMPO spectrometer is the prototype for a similar Differential Fourier Transform Spectrometer to be flown on the Millimetron space mission ....
- So, once again, stratospheric balloons are effectively used as pathfinders for satellite experiments.

# РадиоАстрон

# Millimetron ASC Moscow ROSCOSMOS

- Antenna diameter: 10 m
- Range of wavelengths: 0.01 – 20 mm
- Bolometric sensitivity ( $\lambda$ 0.3mm, 1h integration):  $5 \times 10^{-9}$  Jy
- Interferometry sensitivity ( $\lambda$ 0.5mm, 300s integration, 16GHz bw) :  $10^{-4}$  Jy
- Interferometer beam:  $10^{-9}$  arcsec

3 hours of observations of a rich cluster with a DFTS on Millimetron  
Absolutely outstanding. **USING A PHOTON NOISE LIMITED BOLOMETER IN THE  
COLD ENVIRONMENT OF L2 WITH A 4K TELESCOPE**

# Conclusions

- Balloons offer a great deal of opportunities for CMB research.
- They will add reliability to ground based B-modes measurements (waiting for a final space mission, for which they should be used to qualify instruments / detectors / methods)
- Original/new satellite-based science can and should be first implemented using balloon-borne experiments.
