
**A NUMERICAL MODEL
FOR THE SPATIO-TEMPORAL PROGRAM OF DNA REPLICATION
IN *XENOPUS* EARLY EMBRYOS**

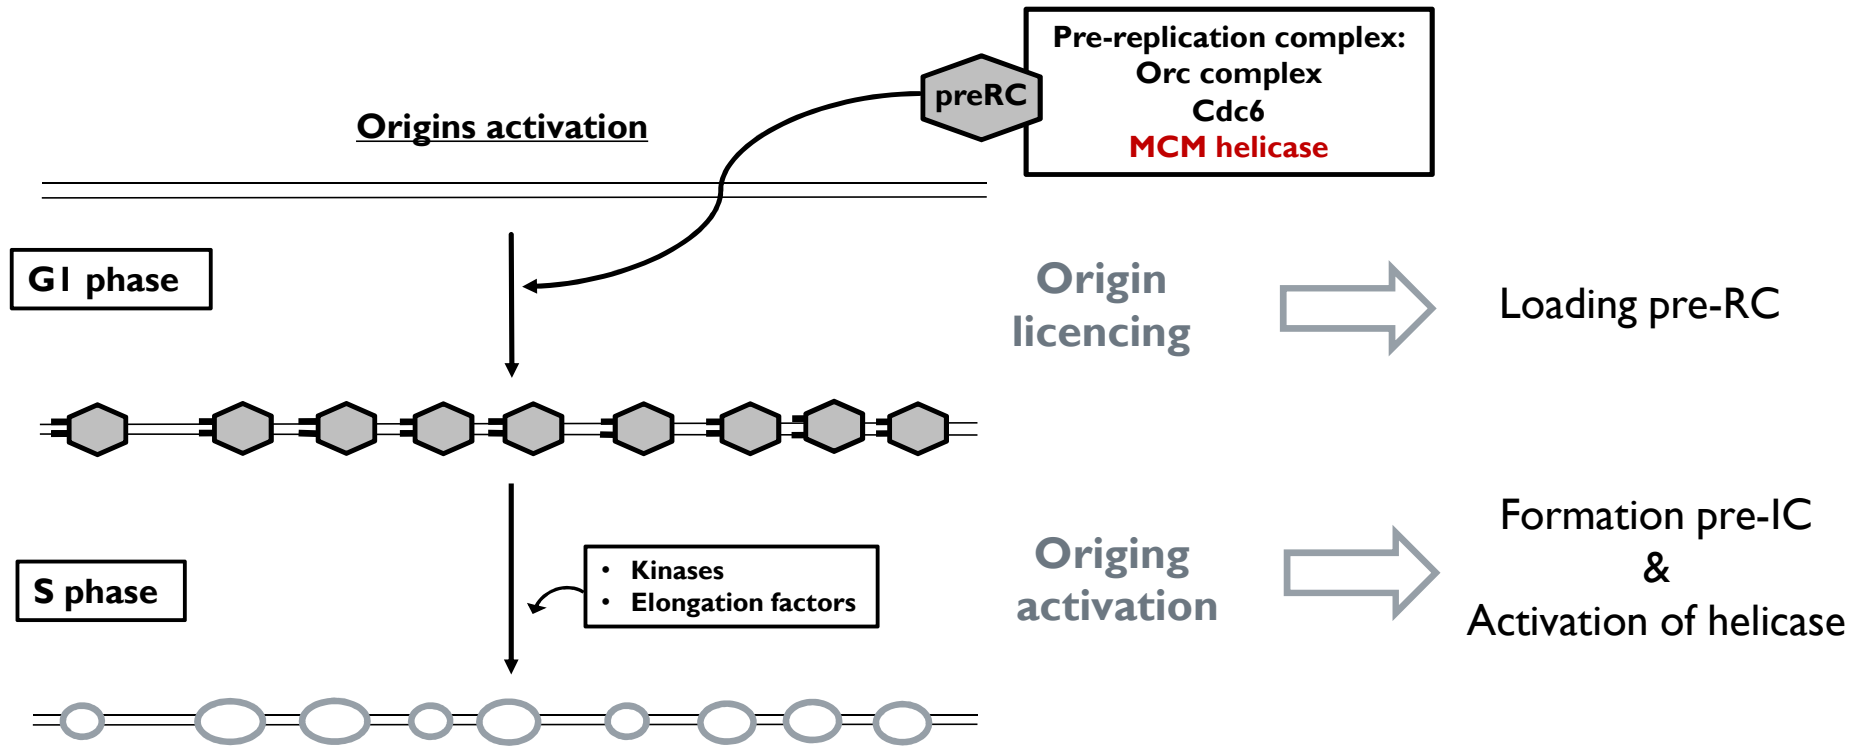

DILETTA CIARDO

SUPERVISORS: KATHRIN MARHEINEKE ,ARACH GOLDAR

**Department of Genome Biology,
Institute for Integrative Biology of the Cell (I2BC)
CNRS, CEA, Paris South University, Gif sur Yvette, France**

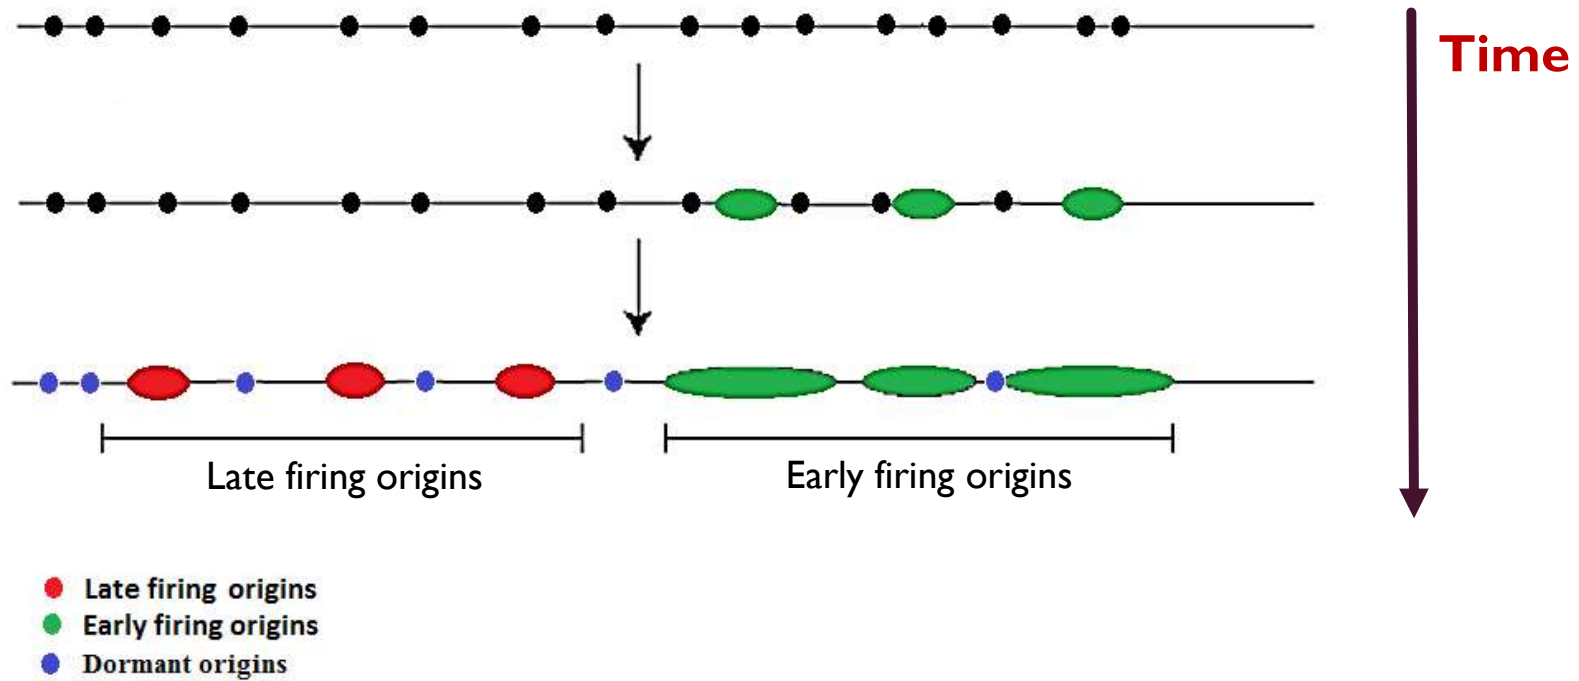

Initiation of DNA Replication origins in eukaryotes:

- Thousands of origins
- No clear consensus sequence for pre-RC binding

Spatio-temporal program of replication:

- Origins grouped in clusters
- Different times of firing

Intra-S phase checkpoint and the spatio-temporal program of replication:

- Activated in response to stalled forks
- Inhibits activation of late origins and delay mitosis entry.
- Hypothesis: Plk1 inhibits Chk1 action also in absence of exogenous replication stress?

Marheineke
&Hyrien (2004)

Trenz et al. (2008)

Platel et al. (2015)

Experimental system:

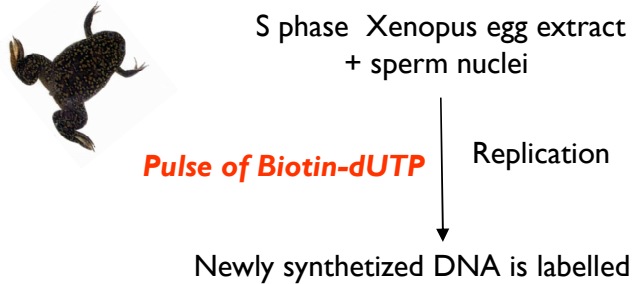

Xenopus laevis in vitro replication system

- Mimics the S phase in early *Xenopus* development
- 100 % replication
- Synchronous S phase entry
- Initiation is sequence independent
- Random initiation
- No trascription

Visualisation of replication origins by DNA combing in the *Xenopus* in vitro system:

1. DNA labelling *in vitro*

2. DNA fiber stretching

Replication parameters:

Replication fraction:

$$f(t) = \frac{\sum_i l_i}{l_{TOT}}$$

Fork density:

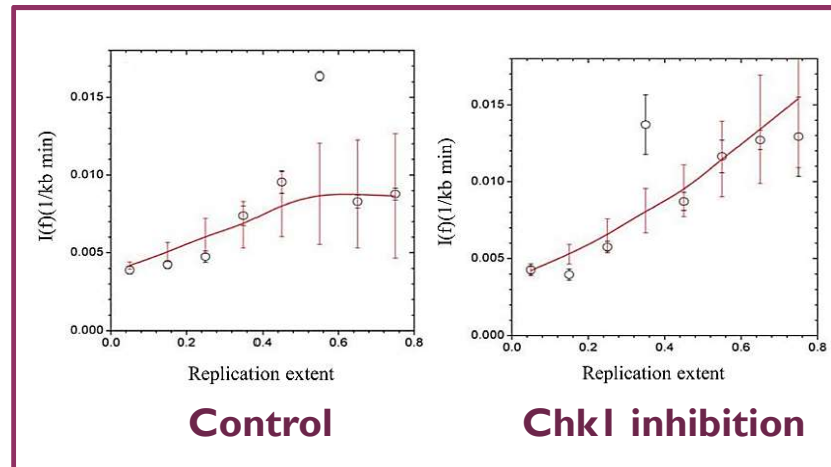

$$N_f(t) = \frac{N_{fork}}{l_{fiber}}$$

Frequency of initiation:

$$I(t) = \frac{N_{origins}}{(1 - f(t)) * l_{fiber} * \Delta t}$$

Analysis of temporal program of replication in *Xenopus* early embryos:

Temporal program:
(Monte Carlo numerical simulations with simplex optimization algorithm)

Platel et al. (2015)

Result:
Inhibition of late firing origins in late clusters, but not in already active clusters

Limiting factor

P_0

P_{polo} : Probability of action of Plk I
 P_{chk1} : Probability of action of Chk I
 P_{init} : Probability of action of limiting factor
 d_{polo} : Distance of action of Plk I

Number of Chk I and Plk I exactly equal to the number of forks

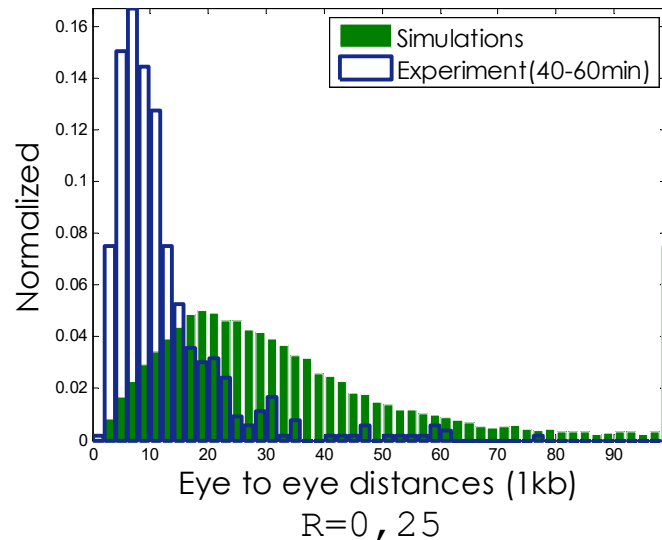

Objectives:

- Understand if the model can reproduce the **spatial program of DNA replication** in *Xenopus* early embryos
 - Comparison of numerical and experimental eye-to-eye distance (ETED) distributions

Previous model does not reproduce the special program of replication:

Extraction of the ETED distribution using the previous model (Monte Carlo simulations):

Parameters:

No: 1	d _{polo} : 45000
J: 4/120	N _{Chkl} : 1
P ₀ : 0.01	%Chkl : 1
P _{Chkl} : 0.99	P _{Polo} : 0.01

- Old parameters
- Old scenario
- New code

Analysis of the **spatial** and temporal replication program in *Xenopus early embryos*:

- Consider both spatial and temporal program (ETED considered)
- Length of simulated genome comparable to real length
- Experimental procedure reproduced in simulations
- Time points considered separately

Strategy:

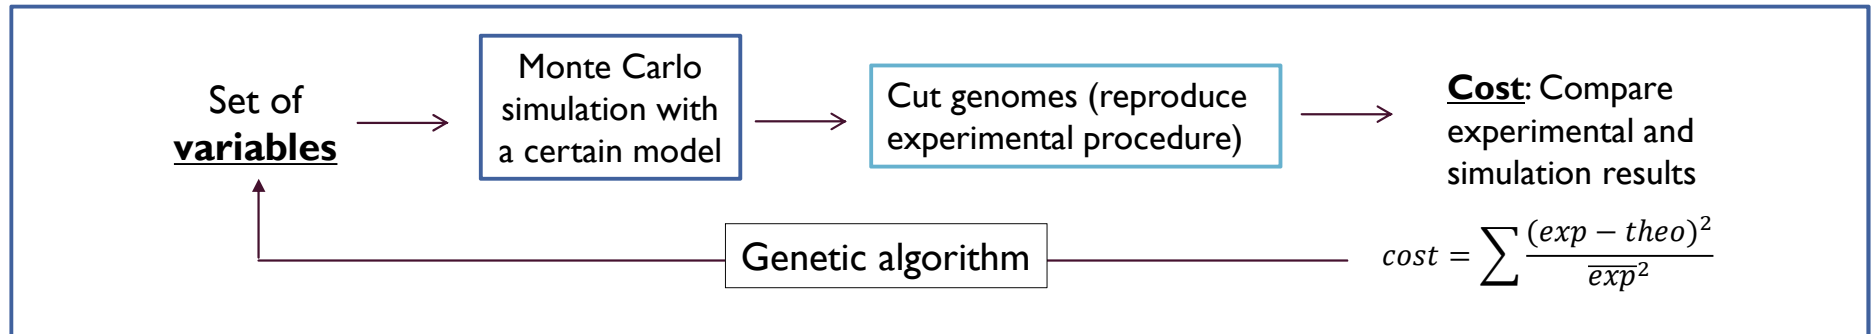

OBJECTIVE: Find a model that describes the experimental data in presence or absence of ChkI inhibition

HOW? Suppose a model and optimize the fit of replication parameters

ALGORITHM:

RESULT: Family of sets of variables of a given model that better describe the experimental data

Dynamic Monte Carlo:

► Initiation

0.51	0.69	0.12	0.35	0.48	0.80	0.94	0.32	0.09	0.55	0.61	0.70	0.41
------	------	------	------	------	------	------	-----	-----	-----	------	------	------	------	------	------

Limiting factor

Select positions with probability lower than a chosen value P_0 (for example 0,15)

0	0	1	0	0	0	0	0	1	0	0	0	0
---	---	---	---	---	---	---	-----	-----	-----	---	---	---	---	---	---

► Elongation

0	1	1	1	0	0	0	1	1	1	0	0	0
---	---	---	---	---	---	---	-----	-----	-----	---	---	---	---	---	---

► Termination/merger

0	1	1	1	0	1	1	1	1	1	0	0	0	0	0	0	0
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

Free one particle of limiting factor

Optimization of different models with genetic algorithm:

Number of variables (k)	Model	Lowest score (cost/(N-k-1))
9		0,1
10	 Forks with action of PlkI chosen randomly at each step	0,14
10	Same as above, but action of PlkI remain on forks until they merges	0,13
10	NO ChkI; higher initiation probability 	0,04
9		0,16
8		0,14

Legend:

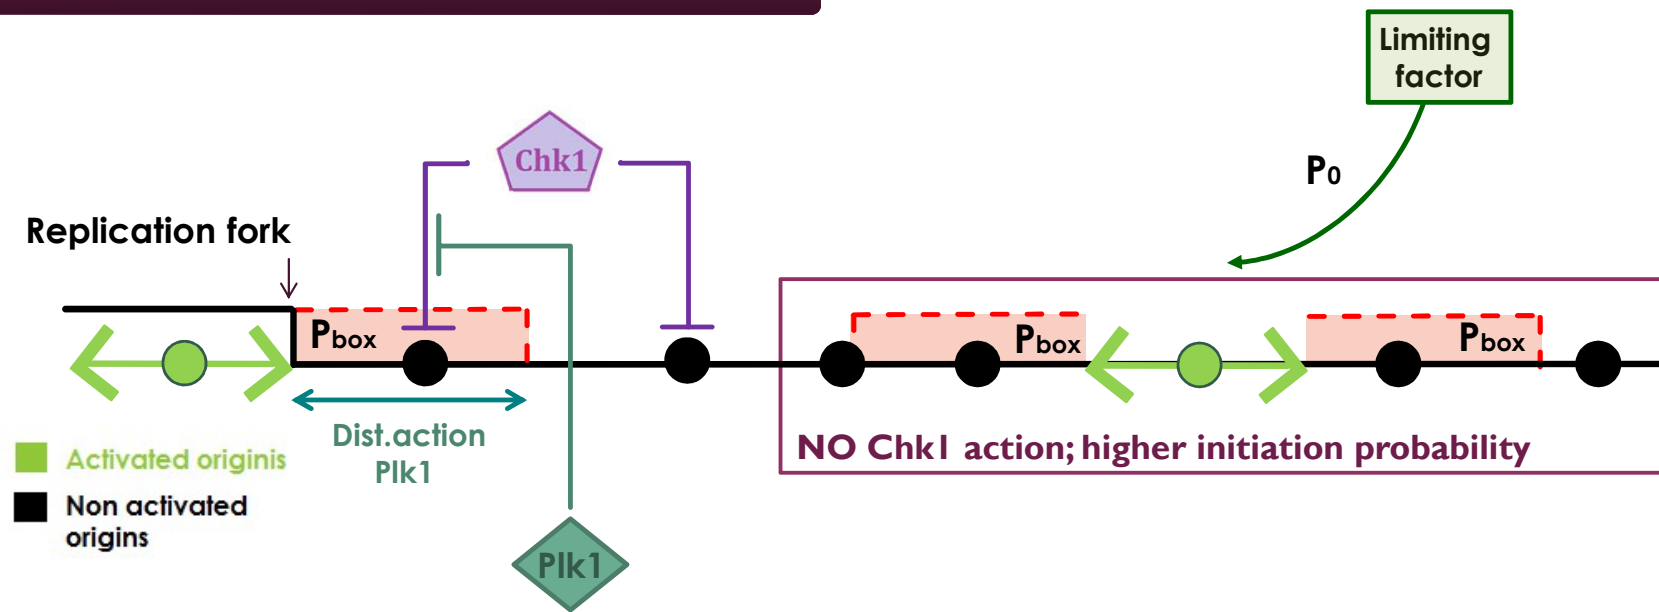

- Origin
- ▶ Fork
- ⋯ Action PlkI and Pbox

N=87 Num. of fitted points
K Num. of variables

Not limited number of potential origins

Limited number of potential origins

Elements of the model:

Parameters:

- N_0 :** initial number of limiting factor
- J :** Rate of import of limiting factor (s^{-1})
- P_0 :** Initial probability of initiation
- P_{Chk1} :** Probability of inhibition by Chk1
- P_{box} :** Increased prob. close to replication forks

- d_{box} :** Distance of action of P_{box} and $Plk1$ (kb)
- $N_{regions}$:** Number of regions
- $D_{regions}$:** Half of the length of regions (kb)
- P_{Plk1} :** Prob. of action of $Plk1$

Results from best model (Absence of ChkI inhibition):

Analysis of early S phase:

Parameters:

N_0 : initial number of limiting factor

J : Rate of import of limiting factor (s^{-1})

P_0 : Initial probability of initiation

P_{ChkI} : Probability of inhibition by ChkI

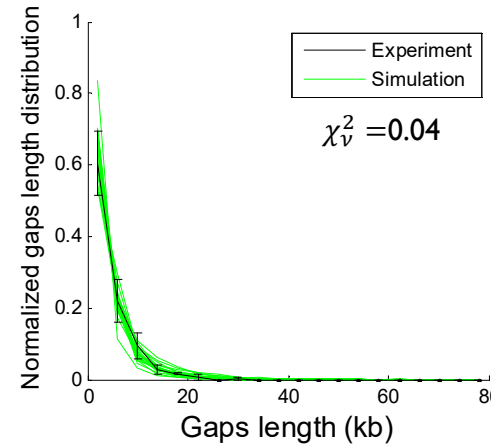

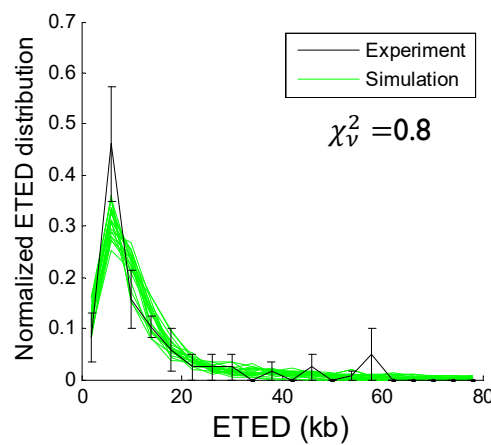

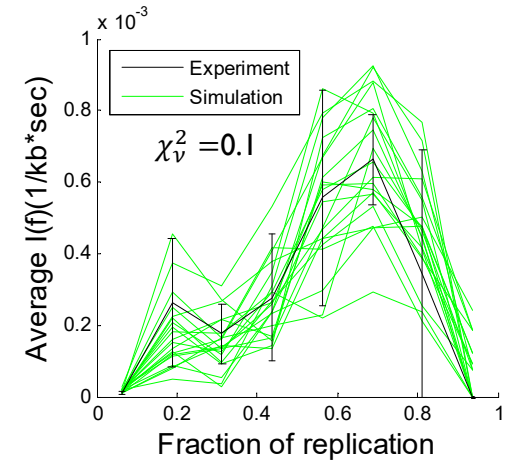

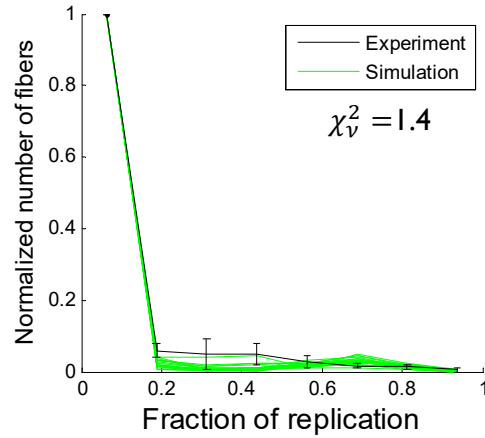

P_{box} : Increased prob. close to replication forks

d_{box} : Distace of action of P_{box} and PlkI (kb)

$N_{regions}$: Number of regions

$D_{regions}$: Half of the length of regions (kb)

P_{Polo} : Prob. of action of PlkI

Results from best model (ChkI inhibition):

Analysis of early S phase:

Parameters:

N_0 : initial number of limiting factor

J : Rate of import of limiting factor (s^{-1})

P_0 : Initial probability of initiation

P_{ChkI} : Probability of inhibition by ChkI

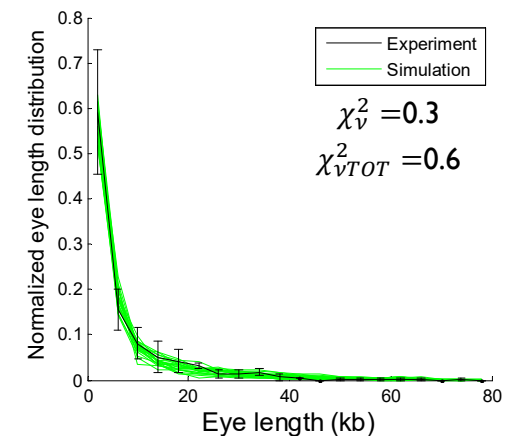

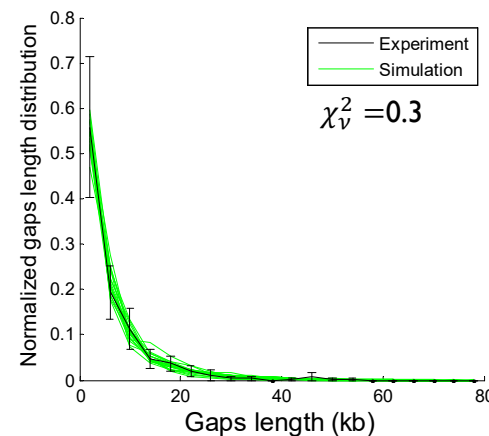

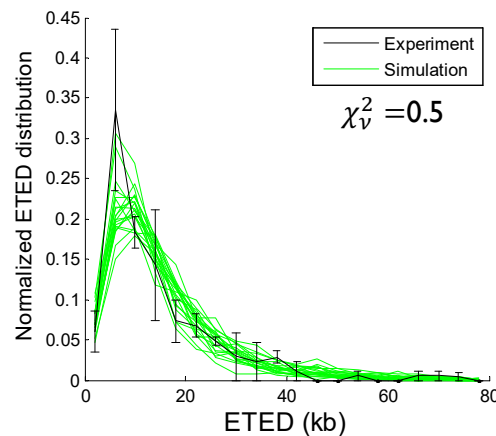

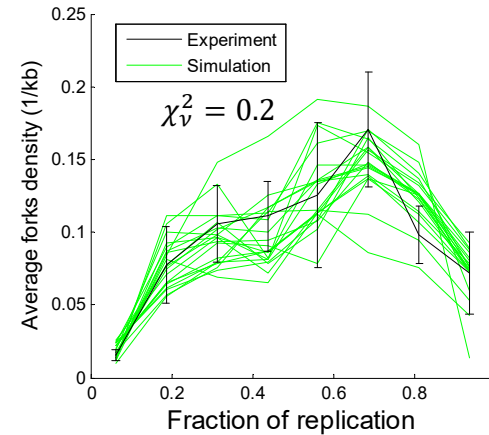

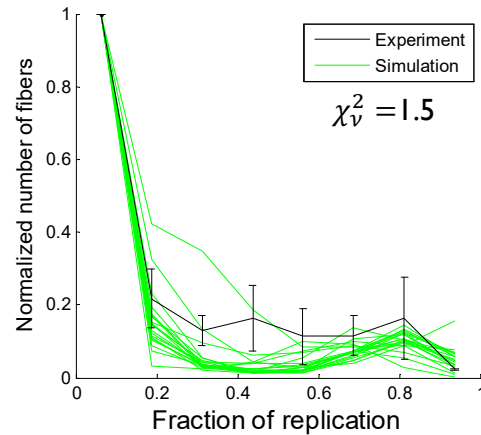

P_{box} : Increased prob. close to replication forks

d_{box} : Distace of action of P_{box} and PlkI (kb)

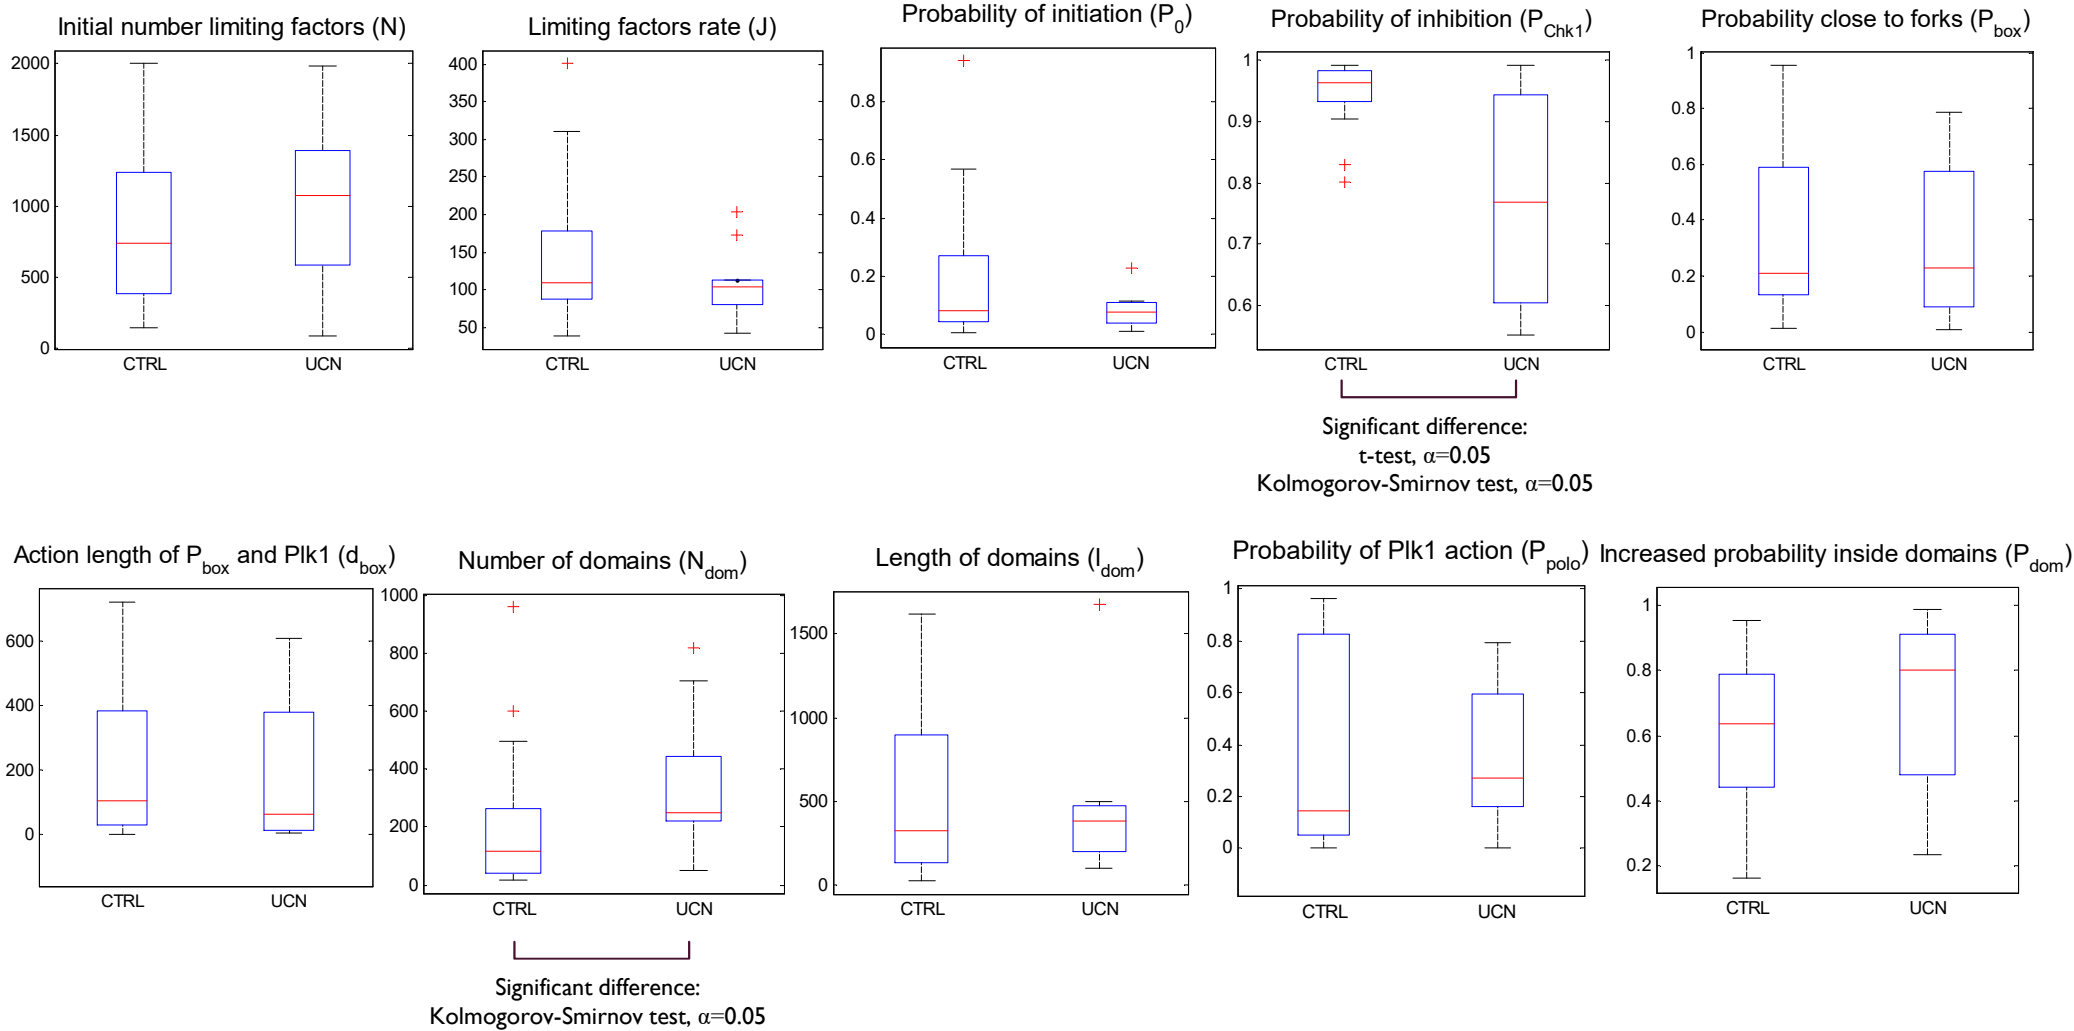

$N_{regions}$: Number of regions

$D_{regions}$: Half of the length of regions (kb)

P_{Polo} : Prob. of action of PlkI

Comparison family of sets in absence and presence of Chk1 inhibition:

Best model:

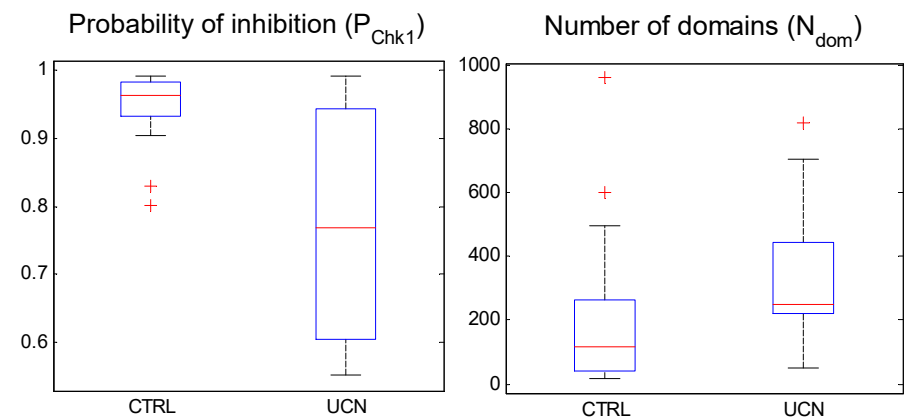

Random initiation by limiting factor with inhomogeneous inhibition of initiation by Chk1

Conclusions:

- Limiting factor interacting with probability P_0 everywhere
- Probability increase close to replication forks (Pbox) (Guilbaud et al. (2011), Lob et al. (2016))
- Strong inhibition of origin initiation by Chk1
- Inhibition of Chk1 action by Plk1 close to active forks
- Regions without action of Chk1, with high probability of origins initiation (Initiated early in S phase)
- Length of domains:

$$\bar{l}_{CTRL} = 1030 \pm 220kb, \quad \bar{l}_{UCN} = 911 \pm 201kb$$

Formation and activation of DNA Replication origins in eucaryotes:

A two step process:

1. Origin licencing

Loading pre-RC

2. Oring activation

Formation pre-IC

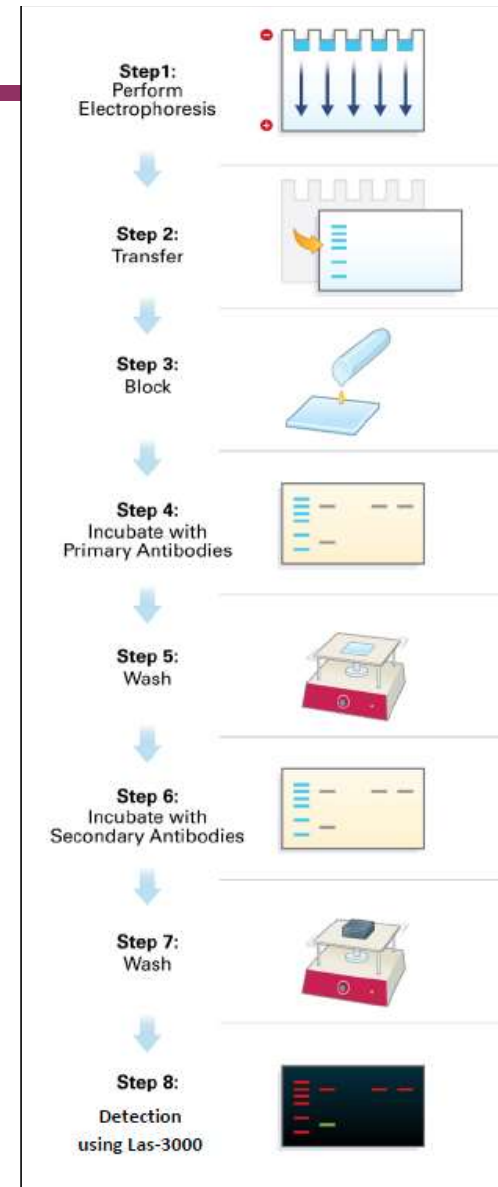

Activation of helicase

SDS-PAGE (Sodium Dodecyl Sulphate-Polyacrylamide gel electrophoresis) and Western Blot

- The SDS-PAGE gel electrophoresis separate the proteins by size;
- SDS is applied to protein samples to linearize proteins and to impart a negative charge (uniform distribution of charge per unit mass);
- The protein of interest interacts with a specific antibody (primary antibody);
- A second antibody (linked to the horseradish peroxidase) binds to the primary and allows the detection by the use of a Chemiluminescence kit.

The enzyme horseradish peroxidase (HRP) catalyses the oxidation of luminol. The reaction is accompanied by emission of light.

DNA combing technique:

- Replication can be followed by the incorporation of Biotin-dUTP;
- The pH dependent interaction between DNA and the hydrophobic coverslip and the air-solution meniscus allows the stretching of the fibers across the glass surface;
- The biotin labelling is realized by a succession of five incubations alternating between Streptavidin Alexa Fluor 594 and biotinylated anti-Streptavidin antibodies;
- Totality of DNA is labelled with human anti-DNA antibody followed by Alexa Fluor 488 anti-mouse and anti-rabbit .

1. DNA labelling *in vitro*

2. DNA fiber stretching

3. DNA labelling

Causes of replication stress:

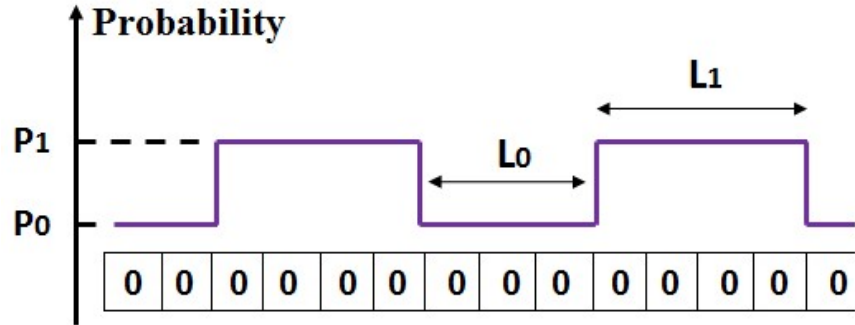

Internal replication stress is generally present in the replication process:

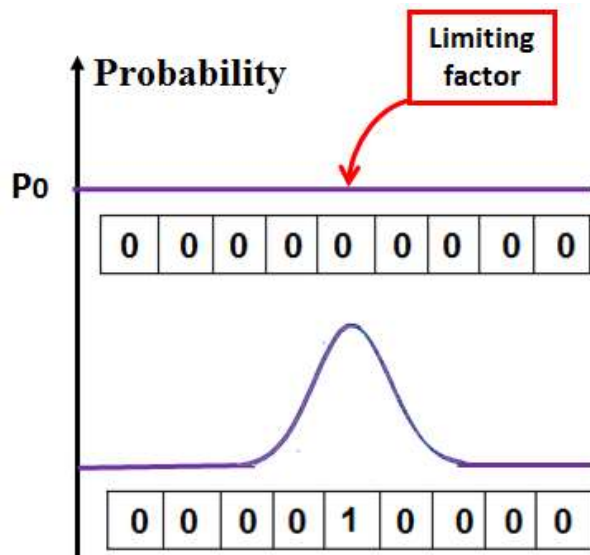

Scenario: Random initiation by limiting factor

Scenario: Random initiation by limiting factor on preferential genomic loci

Scenario: Random initiation by limiting factor whose number is enhanced near activated origins

GENETIC ALGORITHM

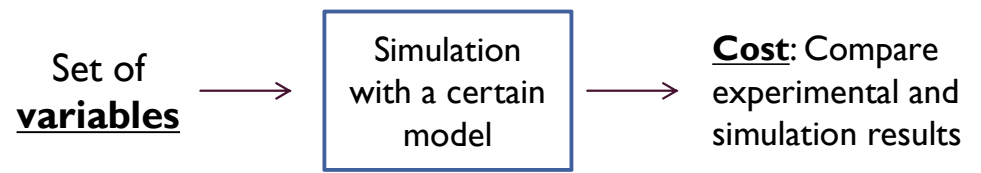

It is an optimization and search technique based on the principles of genetic recombination and natural selection.

EXAMPLE:
Optimization of a two variables problem.

Variables: $[x,y]$
Cost function: $1.1x\sin(2x) + y\sin(4y)$

OBJECTIVE:
Find the set of variables that minimize the cost.

$$cost = \sum \frac{(exp - theo)^2}{exp^2}$$

GENETIC ALGORITHM

Define cost function, cost, variables
Select GA parameters

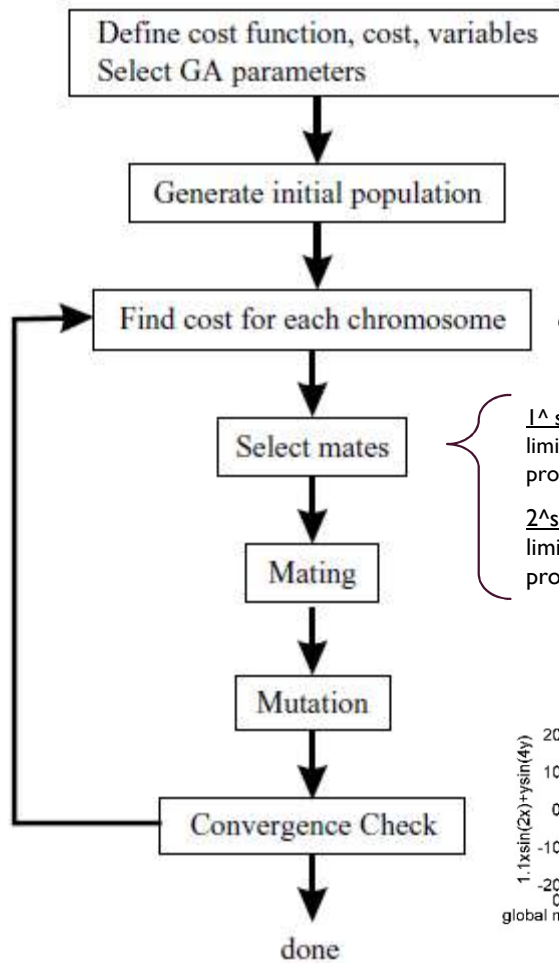

Generate initial population

Set of 11 variables (**chromosome**):

limitfactor max:788375, ratej:2870.327, prob init:0.39965, perc probinit:0.8825, initn chk1:575553,
perc chk1:6.761, prob pchk1:0.046096, prob box:0.88395, dist box:14, prob polo:0.40167, perc polo:0.45698

GENETIC ALGORITHM

$$cost = f(chromosome) = \sum \frac{(exp - theo)^2}{exp^2}$$

1^set of variables:

limitfactor max:788375, ratej:2870.327, prob init:0.39965, perc probinit:0.8825, initn chk1:575553, perc chk1:6.761, prob pchk1:0.046096, prob box:0.88395, dist box:14, prob polo:0.40167, perc polo:0.45698

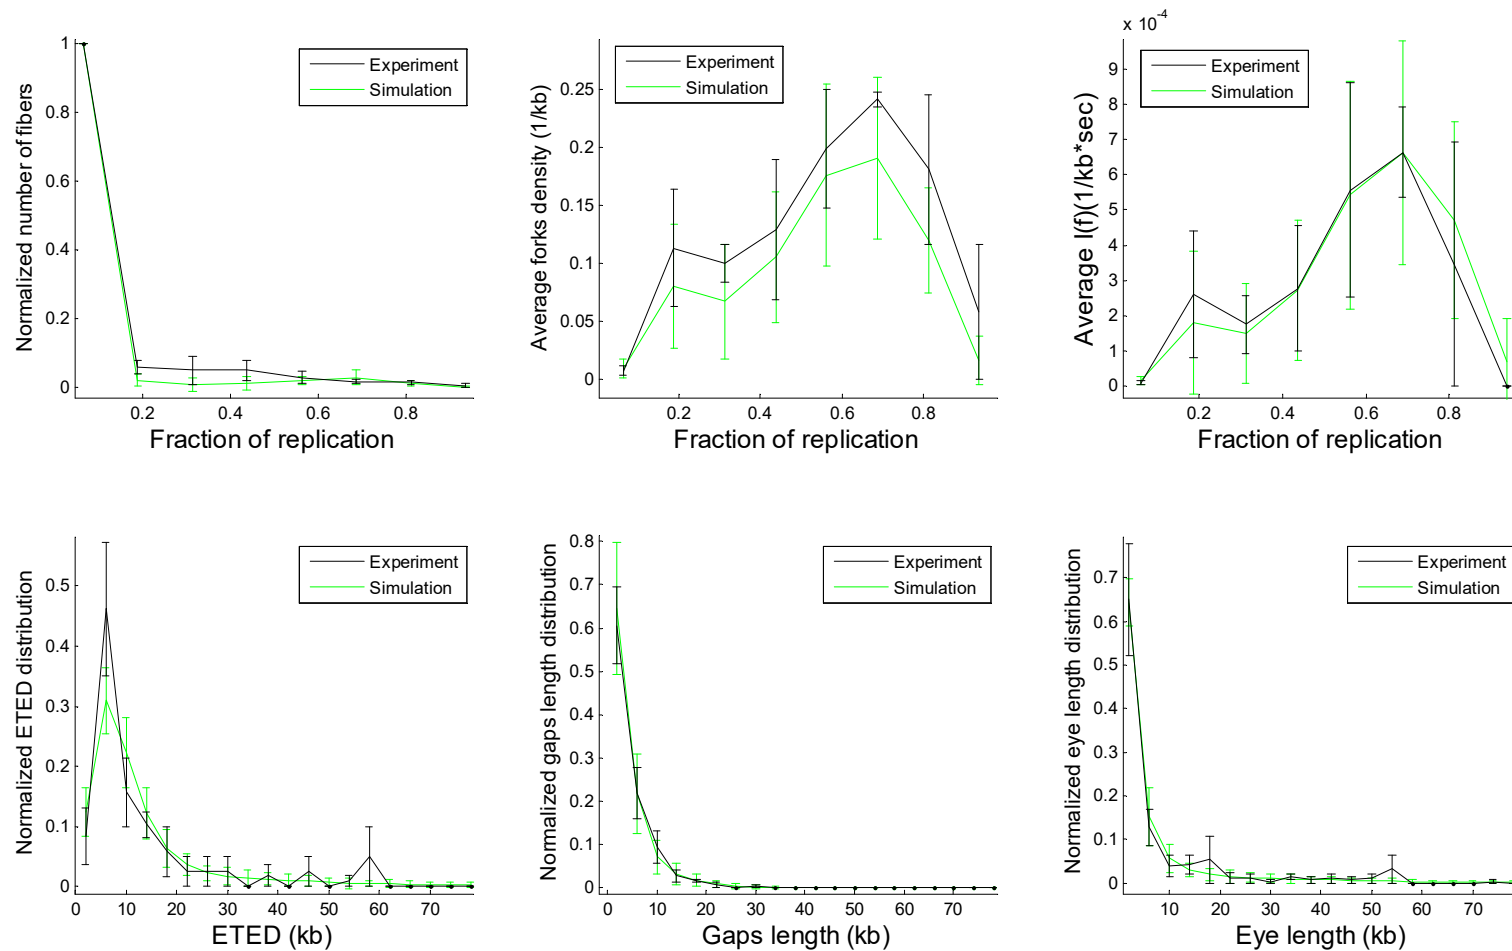

2^set of variables:

limitfactor max:415006, ratej:261.8735, prob init:0.018647, initn chk1:944780, perc chk1:3.0418, prob pchk1:0.99047, prob box:0.84097, dist box:52, prob polo:0.97729, perc polo:0.076676
