

Search for $t\bar{t}$ resonance in ATLAS

William BARBE

Laboratoire de Physique de Clermont

Thursday, April 25th 2019

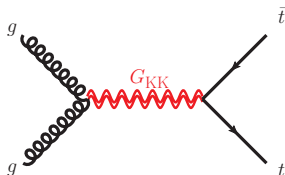

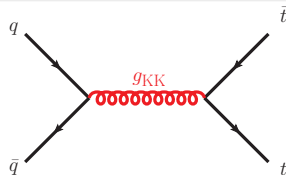

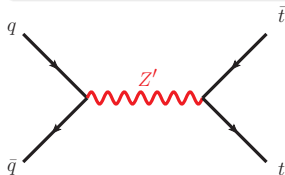

- 1 Introduction
- 2 Results with partial run 2 with 36.1 fb^{-1} data
- 3 Functional decomposition
- 4 Strategy to validate FD
- 5 Summary

$t\bar{t}$ + jets analysis in a nutshell

Search for new resonance decaying into a top quark pair

- ★ Search for resonances in the $t\bar{t}$ mass spectrum predicted by BSM theories (Z' , KK gluon, KK graviton ...)
- ★ 1 lepton top-antitop final state $t\bar{t} \rightarrow WbWb \rightarrow l\nu bqq'b$
- ★ Signature with high p_T lepton, large MET and hadronic jets

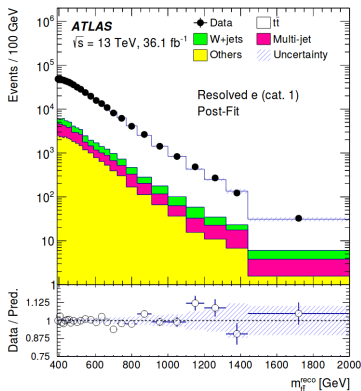

Analysis presented in the last Top LHC France

I will just give a summary of the results using partial run 2 data (36.1 fb^{-1}) and then show the methods that are being investigated for bkg estimation using full run 2 data

Results with partial run 2 data (36.1 fb^{-1})

Type	Yields			
	Boosted e	Boosted μ	Resolved e	Resolved μ
$t\bar{t}$	$28\,500 \pm 500$	$26\,000 \pm 400$	$231\,100 \pm 1900$	$225\,300 \pm 1700$
W+jets	2200 ± 240	2200 ± 180	9400 ± 1100	$10\,300 \pm 800$
Multi-jet	2000 ± 400	780 ± 200	8200 ± 1400	7400 ± 1400
Others	2880 ± 230	2420 ± 180	$13\,000 \pm 600$	$12\,000 \pm 500$
Total	$35\,600 \pm 500$	$31\,300 \pm 300$	$262\,200 \pm 1200$	$254\,600 \pm 1100$
Data	35612	31188	261554	254277

★ Search for excesses in the top-antitop mass spectrum

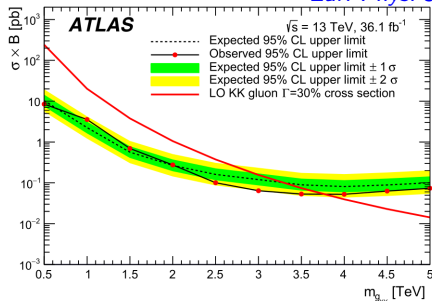

- **good agreement** in all the 12 signal regions
- **exclusion limits** set on benchmark models

<https://arxiv.org/abs/1804.10823>
Eur. Phys. J. C 78 (2018) 565

Results with partial run 2 data (36.1 fb⁻¹)

★ Limits are set on benchmark model productions cross-sections :

→ Z', KK gluon (g_{KK}), KK graviton <https://arxiv.org/abs/1804.10823>
Eur. Phys. J. C 78 (2018) 565

Summary of 95 % Confidence Level mass exclusion ranges on benchmark models

Model	Observed excluded mass [TeV]	Expected excluded mass [TeV]
Z'_{TC2} (1% width)	< 3.0	< 2.6
$Z'_{\text{DM,ax}}$	< 1.2	< 1.4
$Z'_{\text{DM,vec}}$	< 1.4	< 1.6
G_{KK}	$[0.45, 0.65]$	$[0.45, 0.65]$
g_{KK} (15% width)	< 3.8	< 3.5
g_{KK} (30% width)	< 3.7	< 3.2

From 36.1 to 150 fb⁻¹

- ★ 36.1 fb⁻¹ analysis : backgrounds mostly from MC samples
- ★ W + jets and multijet contributions were estimated **from data** :
 - W + jets → **scale factors** derived from data, applied to correct the normalization given by MC simulation
 - multijet → estimated using the **matrix method** (trickier and trickier when the trigger isolation get close to the analysis one)
- ★ O(100) systematics, 12 channels with O(20) bins and large statistic
 - ⇒ profiling is very challenging
 - ⇒ more than 6 months to tune the fit
- ★ For full run 2 data : try data-driven bkg estimate → **Functional Decomposition (FD)**
 - avoid all the above issues
 - using (almost) only the data (MC needed only for the signal and tests)

Functional decomposition (FD)

- ★ Method to fit falling smooth background
- ★ Decompose data into moments : use first few moments for bkg estimation
- ★ Higher moments used to estimate the resonants contributions
- ★ FD's paper : <https://arxiv.org/pdf/1805.04536.pdf>

Advantages

- ★ No fake estimate
- ★ no more need to spend months to tune the fit
- ★ Using (almost) only the data (MC needed only for the signal and to validate the method)
- ★ Can in principle represent any shape
- ★ Model full spectra

Basics of FD

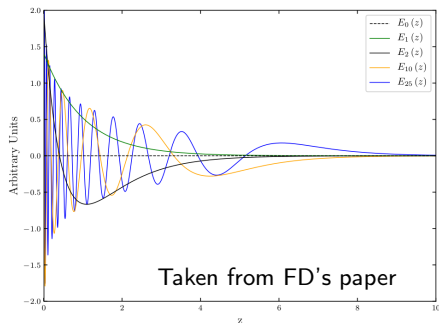

- ★ Based on a set of complete, orthonormal functions
 - orthonormalize $F_n(z) = \sqrt{2}e^{-nz}$
 - Solution :

$$\phi_n = \sqrt{1 - \frac{1}{n^2}}$$

$$E_1(z) = \sqrt{2}e^{-z}$$

$$E_{n+1}(z) = \left(4e^{-z} - \frac{2}{\phi_{2n}^2}\right) \frac{E_n(z)}{\phi_{2n+1}} + \phi_{2n-1} \frac{E_{n-1}(z)}{\phi_{2n+1}}$$

- ★ Recursion relations \rightarrow fast evaluation of $E_n(z)$

Coordinate transform

- ★ We need to ensure that the **tail is well modeled** :
 - all orthonormal exponentials approach e^{-z} as $z \rightarrow \infty$
 - hyperparameters adjust the shape of the tail
- ★ To do that, a coordinate transform is used :

$$z = \left(\frac{x - x_0}{\lambda} \right)^\alpha$$

- x is the variable of interest ($m_{t\bar{t}}$)
 - z is the corresponding dimensionless variable
 - **dataset** $\{x_m\} \Leftrightarrow \{z_m\}$
- ★ Hyperparameters :
 - x_0 : lower mass cut (offset)
 - λ : mass scale
 - α : dimensionless exponent

Choice of hyperparameters crucial for FD's efficiency

Hyperparameters optimization

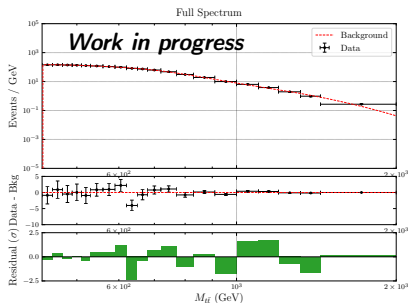

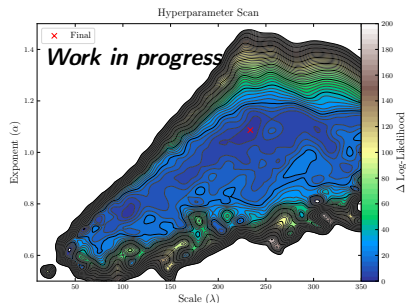

- ★ Selection of λ and α can **greatly affect** the number of terms \mathcal{N} needed to model the background
- ★ Hyperparameters are chosen in order to **minimize** :

$$\mathcal{L} = \text{LogP}(\text{Data}, \text{Model}) + \ln\left(\frac{M}{\mathcal{N}_e}\right)$$

- LogP : represents the amount of information to **encode the data** given the model (ie the compatibility of the data with the model)
- Penalty term : amount of information to **encode the model**

Fit on $m_{t\bar{t}}$

- ★ Dataset $\{z_m\}$ of M unbinned datapoints : $\Omega(z) = \sum_{n=0}^{\mathcal{N}-1} f_n E_n(z)$
 - f_n : coefficients of the background distribution
 - $E_n(z)$: the orthonormal exponentials
- ★ Fit on $m_{t\bar{t}}$: pseudo-data made of $t\bar{t}$ and W+jets MC samples
- ★ FD searches for the best (λ, α) :
 - test various number of moment \mathcal{N} for bkg modeling
 - the couple (λ, α) and \mathcal{N} that give the **minimal** \mathcal{L} are chosen

In all the presentation : FD is used on **pseudo-datas**

Including signal contributions

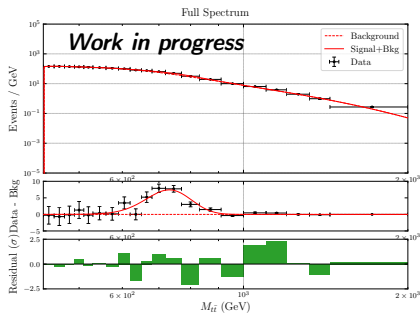

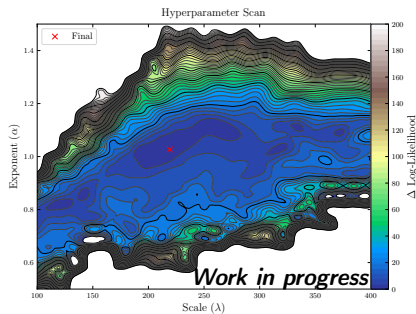

- ★ Dataset $\{z_m\}$ of M unbinned datapoints :

$$\Omega(z) = \sum_{n=0}^{\mathcal{N}-1} c_n E_n(z) + \sum_{m=0}^{N_s} s_m S_m(z)$$

- c_n : coefficients of the background distribution
 - $E_n(z)$: the orthonormal exponentials
 - s_m : signal normalization
 - $S_m(z)$: number of N_s resonant contributions
- ★ First few \mathcal{N} moments are enough to describe the bkg
 - $c_n = 0$ if $n \geq \mathcal{N}$
 - ★ Estimating c_n and s_m with the **method of the moments**
 - decompose the data into moments \tilde{f}_n
 - extract the signal contributions
 - bkg coefficients : $c_n = \tilde{f}_n - s_m \tilde{S}_{(m)n}$, $n < \mathcal{N}$

Fit on $m_{t\bar{t}} + Z'$

- ★ Fit on $m_{t\bar{t}}$:
 - same pseudo-data as before ($t\bar{t}$ and W+jets)
 - a Z' of 750 GeV has been injected in the pseudo-data
- ★ Knowing where the signal is, possible to fit it (here assuming a gaussian shape for the signal)
- ★ FD searches for the best (λ, α)

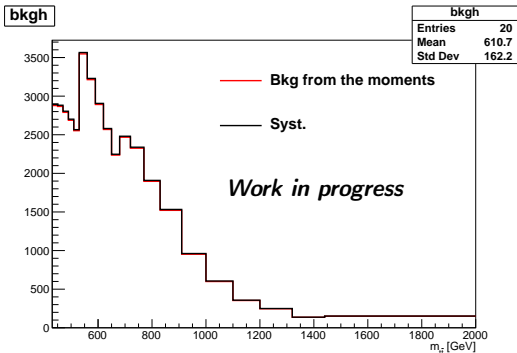

In all the presentation : FD is used on **pseudo-datas**

Possible to extract the syst. on the fit (cf slide 14)

Errors on the fit

- ★ Errors on the fit are accessible
 - covariance matrix computed by FD
- ★ These errors can be used as systematics when running BH

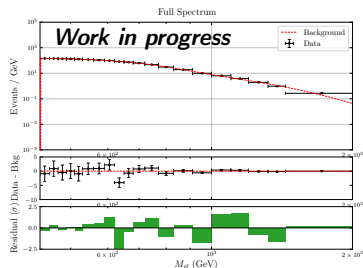

Strategy to validate FD

- ★ Check FD does not produce **spurious signal** :
 - generate many pseudo-data under B-only hypothesis → estimate bkg shape from FD
 - search for the **most significant bump**, and evaluate its significance
- ★ Check FD does not **absorb the signal** in the fit
 - inject various signal (mass, width, strength)
 - compare FD's performances with MC based analysis

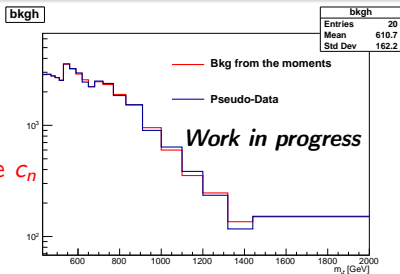

Strategy for the spurious signal study (1)

Get the bkg estimate from FD

- ★ Idea : FD + *BumpHunter*
- ★ First, **run FD** on pseudo-data
- ★ Get the **moments c_n** used by FD to model the bkg
- ★ Reconstruct the background estimate from the fit
- ★ Convert it in histogram

⇒
get the c_n

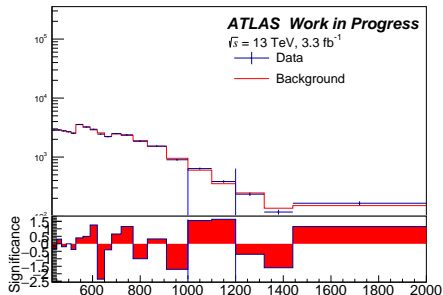

Strategy for the spurious signal study (2)

- ★ We have the bkg estimate and the pseudo-data
- ★ Run *BumpHunter* with the bkg estimate from FD (as we would do in the analysis)

BumpHunter returns the intervall with the most significant excess/deficit with a global p-value

Repeat the procedure for several pseudo-data sets

⇒ *distribution* of global p-values

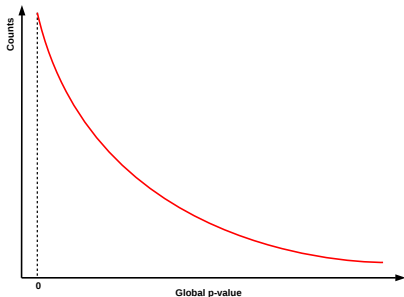

$$p\text{-val}^{local} = 0.013$$

$$p\text{-val}^{global} = 0.205$$

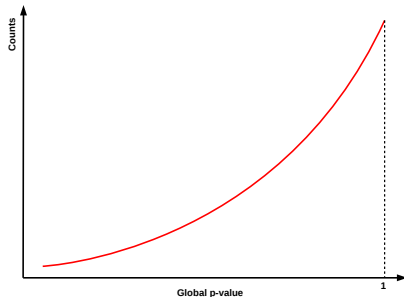

Strategy for the spurious signal study (3)

- ★ The shape of the distribution tell us if the fit is creating spurious signal
- ★ If the distribution is **bias toward 0** → **spurious signal !!**
- ★ If the distribution is **bias toward 1** → FD is **fitting the fluctuations** (and potentially the **signal !!**)

distribution bias toward 0

→ *BumpHunter* found a **large discrepancy** for a large fraction of pseudo-data

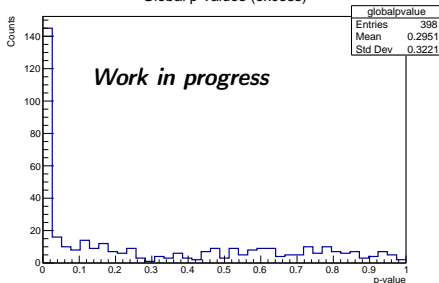

distribution bias toward 1

→ FD is probably using **too much moments** for bkg estimate

Distributions of global p-values

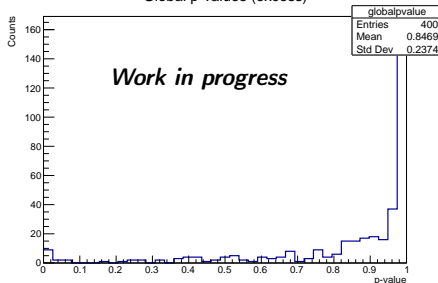

Using old FD

Global p-values (excess)

Using new FD

Global p-values (excess)

★ Peak at 0 for the old FD :

- BH see large discrepancies
- the old FD creates spurious signal

★ Peak at 1 for the new FD :

- the new FD is **more able** to adjust the data when there is **no signal**
- but when there is a signal, fit it as bkg

Old and New FD → 2 ways of defining the likelihood used for the hyperparameters optimization

Signal injection studies

- ★ Check FD does not **absorb the signal** in the fit
 - inject various signal (mass, width, strength)
 - compare FD's performances with MC based analysis

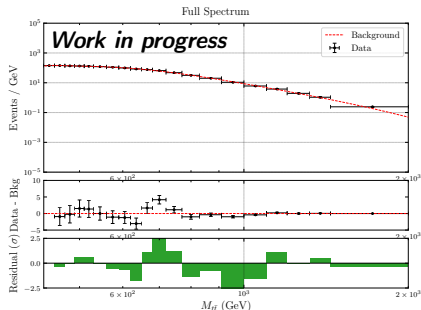

Compare limit sensitivity : MC vs FD

- ★ Compare exclusion upper limit MC vs FD
 - 1) pseudo-data from MC samples → “data”
 - 2) Bkg is either :
 - $t\bar{t}$ and W+jets MC samples
 - FD's bkg estimate

⇒ expected and observed limits for MC and FD
- ★ 2 scenarios for the “data” :
 - SM only
 - SM+ Z' signal
- ★ Compare the 2 versions of FD (old and new)

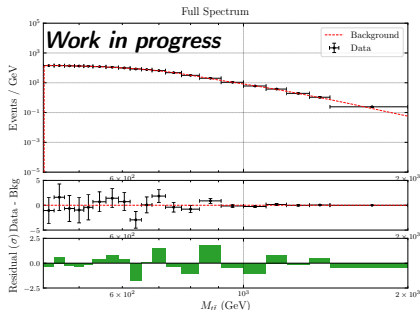

Old vs new FD : fit examples, resolved muon, btag category 3 + Z' of 750 GeV

Old FD

- ★ Excess around 700 GeV ?
- ★ Wave structure in the fit :
 - the signal is perturbing the fit

New FD

- ★ No excess in the fit
- ★ New FD is fitting the signal as bkg

Likelihood definition affect the capability of FD to see or not a signal

Some remarks on FD so far

- ★ Old FD is creating spurious signal
- ★ The new FD **fit the signal as bkg** :
 - more difficult to **find a minimum** (valley less clear in the hyperparameter scan)
 - new FD is more able to adjust the data (good to model the turn-on)
 - **high risk to hide the signal**
- ★ Now working on a **better** definition for the **likelihood**

Summary

- ★ Results with $36.1 \text{ fb}^{-1} \rightarrow$ **no new physics** discovered
 - results were used to set limits on benchmark models production cross-section
- ★ Classical ways for bkg modeling are becoming more and more **difficult** to use with the increase of statistics
- ★ Need to find new ways to model the bkg

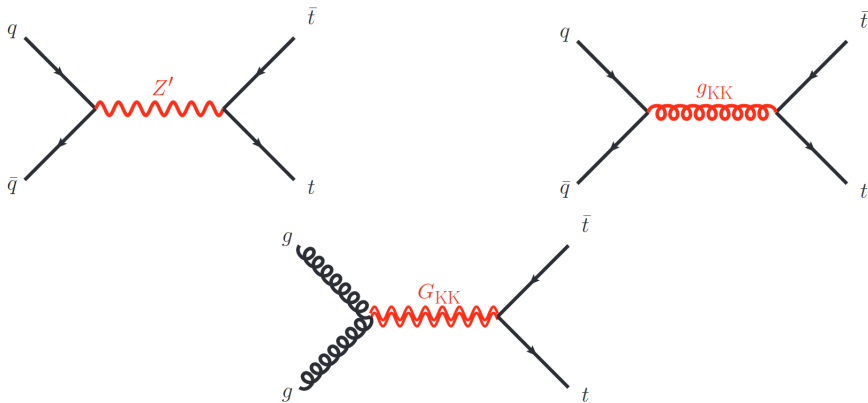

Functional Decomposition

- ★ FD is a tool to fit data and search for new particles
- ★ FD has several **pros** :
 - use only the data
 - can in principle represent any shape
 - no need for MC (except for signal modelization)
- ★ Currently testing FD in $t\bar{t} \text{ l+jets}$:
 - spurious signals
 - signal injection tests

BACK-UP

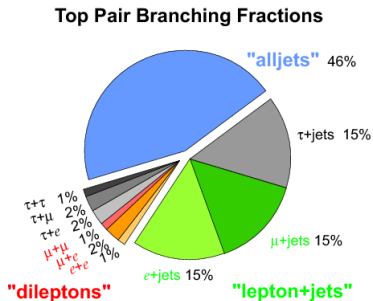

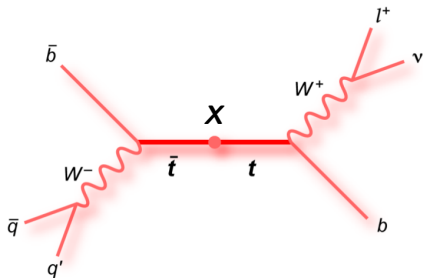

$t\bar{t}$ analysis

- ★ Search for resonances in the $t\bar{t}$ mass spectrum
 - Particles predicted by BSM theories (Z' , KK gluon, KK graviton, 2HDM ...)

$t\bar{t}$ analysis

- ★ Focus on **semi-leptonic** top-antitop final state $t\bar{t} \rightarrow WbWb \rightarrow l\nu bq' b$
 - signature with high transverse momentum lepton, large MET and hadronic jets
- ★ 36.1 fb^{-1} of data at 13 TeV (2015+2016)

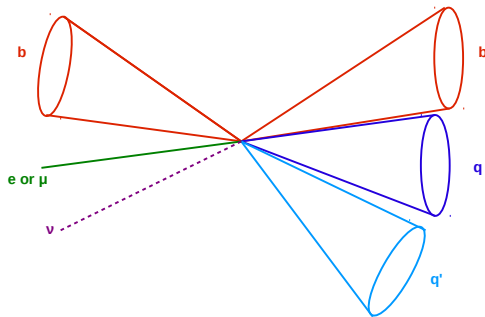

Event selection

- ★ Exactly one electron or muon
- ★ Missing transverse energy (MET)
- ★ At least 1 jet identified as a jet from a b quark (b-tagged)

Resolved selection

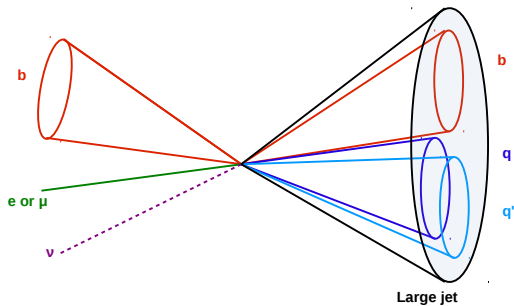

- ★ ≥ 4 small jets

Event selection

Boosted selection

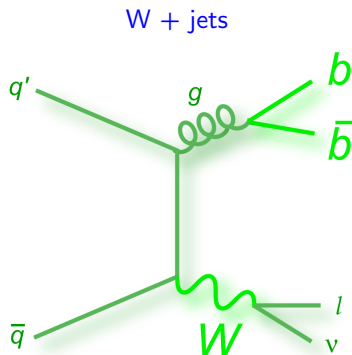

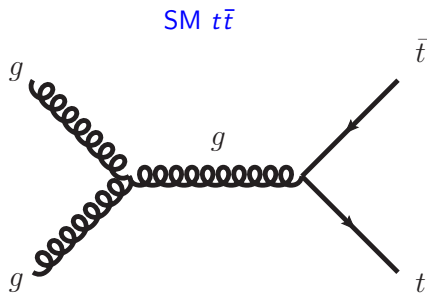

- ★ One large-R jet identified as a jet from a top decay (top boosted \rightarrow decay collimated)

Analysis backgrounds

★ Background contribution to the analysis :

- SM $t\bar{t}$ → dominant contribution
- W + jets
- **Multijet**
- + other backgrounds

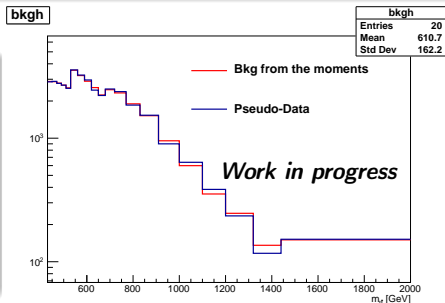

W + jets → events with 1 **isolated lepton** and 1 **neutrino** from W boson decay

BumpHunter

★ Software to search for excess/deficit in a spectrum :

- no signal assumption
- removes the *Look eslwhere Effect*

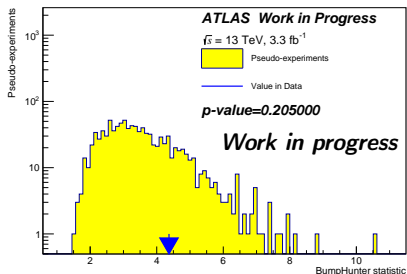

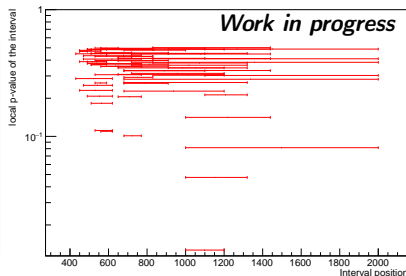

- ★ Consider all possible windows (position and width)
- ★ Count data d_i and bkg b_i in all windows
- ★ Compute the probability that the bkg has fluctuated
→ **local p-value**

BumpHunter

- ★ Distribution of **local p-value**
- ★ Lowest **local p-value** is used to compute BH test statistic :

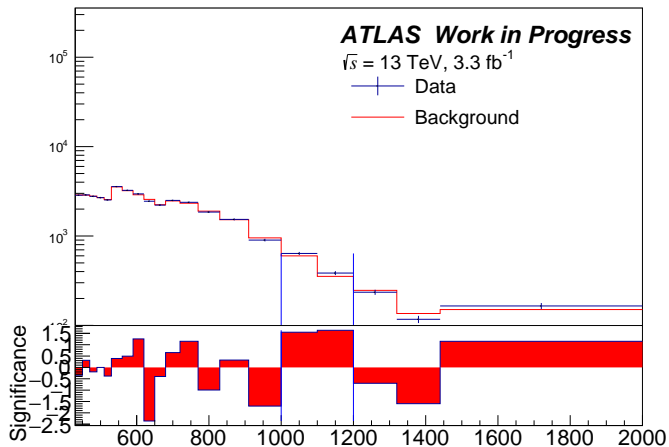

$$t = -\log(\text{p-val}^{\min})$$
- ★ Observed test statistic compatible with bkg hypothesis?

- ★ Pseudo-experiments (PE) generated by MC simulation
 $\rightarrow \text{p-val}^{\min}$ **for each PE**
- ★ Compute a **global p-value** :

$$\text{p-value}^{\text{global}} = \text{fraction of } t_{PE} \geq t_{\text{obs}}$$

BumpHunter result

Return the interval with the most significant excess/deficit with a global p-value

Upper limits from TRex Fitter

Work in progress

Upper limit (pb) rmu3 channel only

		SM only	SM+Z' (750 GeV, $\sigma=1.88$ pb)
MC	expected	$1.88^{2.62}_{1.35}$	$1.88^{2.62}_{1.35}$
	observed	1.68	3.34
New FD	expected	$1.87^{2.62}_{1.35}$	$1.91^{2.67}_{1.38}$
	observed	1.80	1.86
Old FD	expected	$1.87^{2.61}_{1.35}$	$1.87^{2.61}_{1.35}$
	observed	1.94	3.76

The new FD can't see the signal

The old FD has similar sensitivity to MC based bkg
