Pseudoscalar Higgs Boson Decays into W and Z Bosons

Martin Wiebusch in collaboration with W. Bernreuther and P. Gonzalez [arXiv:0909.3772]

Heidelberg, October 2009

Introduction

- The search for spin-zero resonances is among the major goals of present day collider physics.
- $H \rightarrow WW, ZZ$ decays can yield relatively clean signals.
- For a sufficiently heavy *H* they can be the dominant decay modes.
- Non-standard Higgs sectors may also contain pseudoscalar particles.

Vector-like Quarks

Pseudoscalar Higgs Decays

- In models without Higgs sector *CP* violation, there are no tree-level couplings between pseudoscalar Higgses *A* and vector bosons.
- The bosonic sectors of most SM extensions conserve parity.
 - $\Rightarrow AWW$ and AZZ couplings must be induced trough fermion loops.
 - \Rightarrow The branching ratios are usually expected to be small.
- Higgs-fermion couplings can be enhanced by large fermion masses and other model parameters.
- \Rightarrow How large can the $A \rightarrow WW, ZZ$ branching ratios get in different models? Can they be of comparable size as the H branching ratios?

The Two Higgs Doublet Model

Consider a type-II two-Higgs doublet model with a CP invariant tree-level Higgs potential.

Spin zero particle content:

- two neutral scalar Higgses h, H.
- one neutral pseudoscalar Higgs A.
- one charged Higgs H^{\pm} .

Parameters:

- $\tan \beta$ (ratio of the two VEVs).
- Scalar Higgs mixing angle α .

Vector-like Quarks

Conclusions

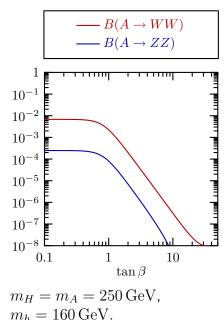

Other decay channels:

$$A \to Zh, \ b\bar{b}, \ \tau\bar{\tau}, \ t\bar{t}, \ gg$$
.

Branching Ratios

For small $\tan \beta$:

- The total width is dominated by $A \rightarrow gg$ decays.
- The $At\bar{t}$ coupling is enhanced by $\cot \beta$.

For large $\tan \beta$:

- The $Ab\bar{b}$ coupling is enhanced by $\tan\beta$, but suppressed by m_b/m_Z .
- The total width is dominated by $A \rightarrow b\bar{b}$ decays.

Mass dependence

 $m_h = 160 \,\mathrm{GeV}.$

Pseudoscalar Higgs Boson Decays into W and Z Bosons

Martin Wiebusch

A 4th Generation of Fermions

- The existence of a 4th generation of heavy chiral fermions $(u_4, d_4, \nu_4, \ell_4)$ is not excluded yet.
- The mass bounds from direct searches at LEP and TEVATRON are

 $m_{u_4} > 311 \,\text{GeV} \ , \ m_{d_4} > 190 \,\text{GeV} \ , \ m_{\nu_4} > 90 \,\text{GeV} \ , \ m_{\ell_4} > 100 \,\text{GeV} \ .$

• Experimental limits on ΔS and ΔT require moderate mass splittings and

$$m_{u_4} > m_{d_4}$$
, $m_{\ell_4} > m_{\nu_4}$.

 $\Rightarrow\,$ We add a 4th generatrion with Dirac neutrinos and

$$m_{u_4} = 320 \,\text{GeV} \;, \; m_{d_4} = 200 \,\text{GeV} \;,$$

 $m_{\nu_4} = 180 \,\text{GeV} \;, \; m_{\ell_4} = 220 \,\text{GeV} \;.$

Two Higgs Doublet

A 4th Generation of

Vector-like Quarks

Vector-like Quarks

- Another possible extension are vector-like quarks, whose leftand right-chiral components have equal gauge charges.
- They are predicted by extra dimensional models with bulk fermions and Little Higgs models.
- They only suffer very weak constraints from electroweak precision observables.
- \Rightarrow We add an SU(2) doublet Q=(U,D) and two SU(2) singlets $U',\ D'$:

$$\begin{split} \mathcal{L}_{\text{VQ,gauge}} &= \quad \bar{Q}i \not\!\!\!D Q + \bar{U}' i \not\!\!\!D U' + \bar{D}' i \not\!\!\!D D' \\ &- M_Q \bar{Q} Q - M_U \bar{U}' U' - M_D \bar{D}' D' \quad, \end{split}$$

$$\begin{split} \mathcal{L}_{\text{VQ,Yuk}} &= -y_U \bar{Q}_L \Phi_u^{\text{c}} U_R' - y_D \bar{Q}_L \Phi_d D_R' \\ &- \tilde{y}_U \bar{Q}_R \Phi_u^{\text{c}} U_L' - \tilde{y}_D \bar{Q}_R \Phi_d D_L' + \text{h.c.} \quad . \end{split}$$

Mass Matrices

After EWSB we get mass matrices

$$\begin{pmatrix} M_Q & y_U v_u \\ \tilde{y}_U v_u & M_U \end{pmatrix} , \begin{pmatrix} M_Q & y_D v_d \\ \tilde{y}_D v_d & M_D \end{pmatrix} ,$$

which can be diagonalised with bi-orthogonal rotations

$$\begin{pmatrix} D \\ D' \end{pmatrix}_{L,R} = \begin{pmatrix} \cos \varphi_{L,R}^D & -\sin \varphi_{L,R}^D \\ \sin \varphi_{L,R}^D & \cos \varphi_{L,R}^D \end{pmatrix} \begin{pmatrix} D_1 \\ D_2 \end{pmatrix}_{L,R} ,$$

$$\begin{pmatrix} U \\ U' \end{pmatrix}_{L,R} = \begin{pmatrix} \cos \varphi_{L,R}^U & -\sin \varphi_{L,R}^U \\ \sin \varphi_{L,R}^U & \cos \varphi_{L,R}^U \end{pmatrix} \begin{pmatrix} U_1 \\ U_2 \end{pmatrix}_{L,R} ,$$

Pseudoscalar Higgs Boson Decays into W and Z Bosons

Martin Wiebusch

Introduction

Two Higgs Doublet Model

A 4th Generation of Fermions

Vector-like Quarks

Parameters

The mixing angles must satisfy

$$t_{L-R}^{U,D} \equiv \tan(\varphi_L^{U,D} - \varphi_R^{U,D}) = \frac{v_{u,d}(\tilde{y}_{U,D} - y_{U,D})}{M_Q + M_{U,D}} ,$$

$$t_{L+R}^{U,D} \equiv \tan(\varphi_L^{U,D} + \varphi_R^{U,D}) = \frac{v_{u,d}(\tilde{y}_{U,D} + y_{U,D})}{M_Q - M_{U,D}} .$$

The mass eigenvalues are

$$m_{U_{1,2}} = \frac{1}{2} \left[\sqrt{(M_Q + M_U)^2 + v_u^2 (y_U - \tilde{y}_U)^2} \pm \sqrt{(M_Q - M_U)^2 + v_u^2 (y_U + \tilde{y}_U)^2} \right]$$
$$m_{D_{1,2}} = \frac{1}{2} \left[\sqrt{(M_Q + M_D)^2 + v_d^2 (y_D - \tilde{y}_D)^2} \pm \sqrt{(M_Q - M_D)^2 + v_d^2 (y_D + \tilde{y}_D)^2} \right]$$

,

For the numerical analysis we choose as independent parameters

$$M_Q = 1 \text{ TeV} , \ m_{U_2} = m_{D_2} = 320 \text{ GeV} ,$$

$$t_{L-R}^U , \ t_{L+R}^U , \ t_{L-R}^D , \ t_{L+R}^D .$$

Results

- Large (small) values of $\tan\beta$ enhance the $AD\bar{D}$ ($AU\bar{U}$) couplings.
- For small $t_{L+R}^{U,D}$ or small $t_{L-R}^{U,D}$ the vector-quark sector becomes parity conserving and does not contribute to $A \rightarrow WW, ZZ$ decays.
- For large $t_{L\pm R}^{U,D}$ the mixing angles approach 0 or $\pm \pi/2$
 - \Rightarrow (most) digagrams get suppressed by factors $\sin\varphi_L^{U,D}$, $\cos\varphi_R^{U,D}$, \ldots
- The vector-quark contributions saturate for $t_{L\pm R}^{U,D} \gtrsim 10$.
- Only small contributions to $A \rightarrow ZZ$ decays.

$$\tan \beta = 0.2 \quad \Rightarrow \quad B(A \to WW) < 2\%$$
$$\tan \beta = 5 \quad \Rightarrow \quad B(A \to WW) < 0.12\%$$

Conclusions

Conclusions

- We studied the $A \rightarrow WW, ZZ$ branching ratios in the (*CP* conserving) 2HDM extended by different types of heavy fermions.
- We find the largest branching ratios for small $\tan\beta$:

 $B(A \to WW) \lesssim 2\%$, $B(A \to ZZ) \lesssim 10^{-3}$.

- \Rightarrow If a spin-zero resonance decays dominantly into WW, ZZ it is most likely CP even.
- \Rightarrow If the WW and ZZ decays of a spin-zero resonance are rare it could be a pseudo-scalar.
