Core-breaking effects around 100Sn: lifetime measurements in the most neutron-deficient Sn isotopes.

mardi 6 juin 2023 15:45 (15 minutes)

The long Sn isotopic chain is a formidable testing ground for nuclear models aiming at describing the evolution of the shell structure. Low-lying excited states roughly exhibits the typical behavior predicted by the generalized seniority scheme. However, the corresponding $B(E2; 0^+ \rightarrow 2^+)$ values, approaching the $N=Z=50$ shell closure, have shown a presumed deviation from the expected parabolic behavior [1]. From a theoretical point of view, various attempts have been done to explain such experimental results, in particular by including core-breaking excitations in the shell-model calculations and promoting protons and neutrons from the $g_{9/2}$ orbital across the shell gap [2]. From the experimental side, limited data are available beyond ^{104}Sn and no lifetime information are known in this extremely neutron-deficient region, leading to a difficulty in a firm evaluation of any core-breaking effects.

In this contribution, we will report recent results on lifetime measurements in $^{102,103}\text{Sn}$. The experiment was performed in May 2021 at GSI using the AIDA Si active stopper surrounded by the EUROBALL HPGe and the FATIMA LaBr₃ array. The nuclei of interest were identified in the FRS separator, following the production via fragmentation reactions of a ^{124}Xe beam on a ^9Be target. The Sn isotopes have been stopped in the AIDA array and the decaying gamma rays collected by the FATIMA array, which allowed for a direct lifetime measurement with a precision up to few tens of ps. The analysis is ongoing and the preliminary results will be presented, together with their possible implications.
