

The MUonE experiment

“We are doing something unique here.”

–Umberto Marconi

Who am I?

- ✦ Matteo Bonanomi, 24yo;
- ✦ MSc in Particle Physics at the University of Milano Bicocca on the **MUonE experiment**;
- ✦ Second year PhD student at École Polytechnique with the CMS experiment;
- ✦ Working on the CMS High Granularity Calorimeter (HCGAL) beam tests analysis;
- ✦ ROOT User/addicted for my analyses ...

Who am I?

- ✦ Matteo Bonanomi, 24yo;
- ✦ MSc in Particle Physics at the University of Milano Bicocca on the **MUonE experiment**;
- ✦ Second year PhD student at École Polytechnique with the CMS experiment;
- ✦ Working on the CMS High Granularity Calorimeter (HCGAL) beam tests analysis;
- ✦ ROOT User/addicted for my analyses ... **before my PhD started** (🐍 😊)

In this presentation

- The Standard Model in a nutshell;
- What is the **muon anomaly**: present and future;
- The **MUonE** experiment:
 - Theoretical framework;
 - Experimental overview and beam tests;
- Conclusions

My MSc thesis

My PhD

What do they have in common?

Matteo in the SM

What do they have in common?

MUonE

CMS

- ✦ Precision frontier;
- ✦ No collider;
- ✦ Small collaboration
O(1e2);

- ✦ High Energy frontier;
- ✦ At LHC;
- ✦ Large collaboration
O(1e3);

✦ **Probe physics BSM;**

The high energy frontier

Le bestiaire

Quarks

Leptons

Bosons

- Why particles have mass?
- From 2012 main focus of the physics at high energy frontier;
- Many precision measurements on Higgs sector ongoing at LHC;
- Possible hints of physics beyond the SM at accelerators;

The precision frontier

Le bestiaire

- ✦ Indirect evidence of physics beyond the SM can come from the **precision frontier**;
- ✦ **BNL, Mainz;**
- ✦ **Flavour factories;**
- ✦ **$g-2$, M2e @Fermilab;**

“g-2: an uncomfortably lonely search for a crack in the SM”

–David W. Hertzog

The $g-2$ anomaly (I)

Magnetic dipole moment of a particle with spin:

$$\vec{\mu} = g \frac{e}{2m} \vec{s}$$

- The constant g is known as **g-factor**;
- Dirac equation predicts $g = 2$;
- Due to QED and QCD effects we have

$$\vec{\mu} = 2(1 + a) \frac{e}{2m} \vec{s}$$

The $g-2$ anomaly (II)

Having spin, they have

$$\vec{\mu} = 2(1 + a) \frac{e}{2m} \vec{s}$$

$a = \frac{g-2}{2}$ is referred to as **anomaly**.

Electron

Muon

$$a_e^{exp} = 1159652180.73(28) \times 10^{-12} \pm 0.24 \text{ ppb}$$

Less sensitive to heavier physics

$$\left(\frac{m_\mu}{m_e}\right)^2 \simeq 43000$$

$$a_\mu^{exp} = 116592089(63) \times 10^{-11} \pm 0.54 \text{ ppm}$$

Strongly affected by hadronic contributions

The a_μ in the SM

$$a_\mu^{SM} = a_\mu^{QED} + a_\mu^{Weak} + a_\mu^{Had}$$

60 ppm on a_μ^{SM}

- a_μ^{QED} : Well known up to 5-loop diagrams;
- a_μ^{Weak} : well known at 1-loop, current work at 2-loops;
- $a_\mu^{Had} = a_\mu^{H-LO} + a_\mu^{H-HO} + a_\mu^{H-LbL}$;

Sensitive to mass scales in $O(1e2)$ GeV region: W, Z bosons and possibly **BSM contributions**.

g-2 theory and experiment

E821 experiment @BNL and SM prediction have a long-standing $\sim 3.7\sigma$ discrepancy

$$\Delta a_\mu^{exp - SM} \simeq (261 \pm 78) \times 10^{-11}$$

g-2 to nail down the 5σ

Theoretical uncertainty limits the SM prediction. Mostly dominated by **hadronic effects** (in particular **H-LO**)

Experimental uncertainty limited by available statistics. New experiments foreseen at **FNAL** and **J-PARC** (**x4 BNL accuracy**)

g-2 to nail down the 5σ

Theoretical uncertainty limits the SM prediction. Mostly dominated by **hadronic effects** (in particular **H-LO**)

Requirement of **experimental data** as input to improve the computation.

How to measure a_{μ}^{H-LO} (I)

Dispersive approach : $a_{\mu}^{H-LO} = \left(\frac{\alpha m_{\mu}}{3\pi} \right)^2 \int_{m_{\pi}^2}^{\infty} \frac{ds}{s^2} K(s) R_{had}(s)$

$$R_{had}(s) = \frac{\sigma_{tot}(e^{+}e^{-} \rightarrow had.)}{\sigma(e^{+}e^{-} \rightarrow \mu^{+}\mu^{-})}$$

How to measure a_{μ}^{H-LO} (I)

Dispersive approach : $a_{\mu}^{H-LO} = \left(\frac{\alpha m_{\mu}}{3\pi} \right)^2 \int_{m_{\pi}^2}^{\infty} \frac{ds}{s^2} K(s) R_{had}(s)$

$$R_{had}(s) = \frac{\sigma_{tot}(e^+e^- \rightarrow had.)}{\sigma(e^+e^- \rightarrow \mu^+\mu^-)}$$

How to measure a_{μ}^{H-LO} (I)

- ✦ Sets the current precision at 3.7σ ;
- ✦ Relies on many **experimental inputs**: BELLEII, BaBar, KLOE...
- ✦ **Hard to compute** in the low E region due to fluctuations.

How to measure a_{μ}^{H-LO} (II)

Alternative approach based on **space-like** phase space integration:

$$a_{\mu}^{H-LO} = \left(\frac{\alpha}{\pi} \right) \int_0^1 dx (1-x) \Delta\alpha_{had}(t(x))$$

- Allows to compute the H-LO contributions in an independent way;
- Space-like phase space only, no channels interference!
- Depends on **the running of α_{em}** ...

... yes, α_{em} is not constant 1/137 😊

How to measure a_{μ}^{H-LO} (II)

Alternative approach based on **space-like** phase space integration:

$$a_{\mu}^{H-LO} = \left(\frac{\alpha}{\pi} \right) \int_0^1 dx (1-x) \Delta\alpha_{had}(t(x))$$

$$\alpha(t) = \frac{\alpha(0)}{1 - \Delta\alpha_{lep}(t) - \Delta\alpha_{had}(t)}$$

How to measure a_{μ}^{H-LO} (II)

$$a_{\mu}^{H-LO} = \left(\frac{\alpha}{\pi} \right) \int_0^1 dx (1-x) \Delta\alpha_{had}(t(x))$$

- Smooth integral, free from resonances: can be fully **extracted from data**;
- Pure *t-like* approach, allows to select channels w/o interference;
- 🤔 ... but how do we measure $\Delta\alpha_{had}(t(x))$?;

The μ ONE experiment

Scattering of high energy muons ($E_\mu \simeq 150\text{GeV}$) on atomic electrons of low Z target

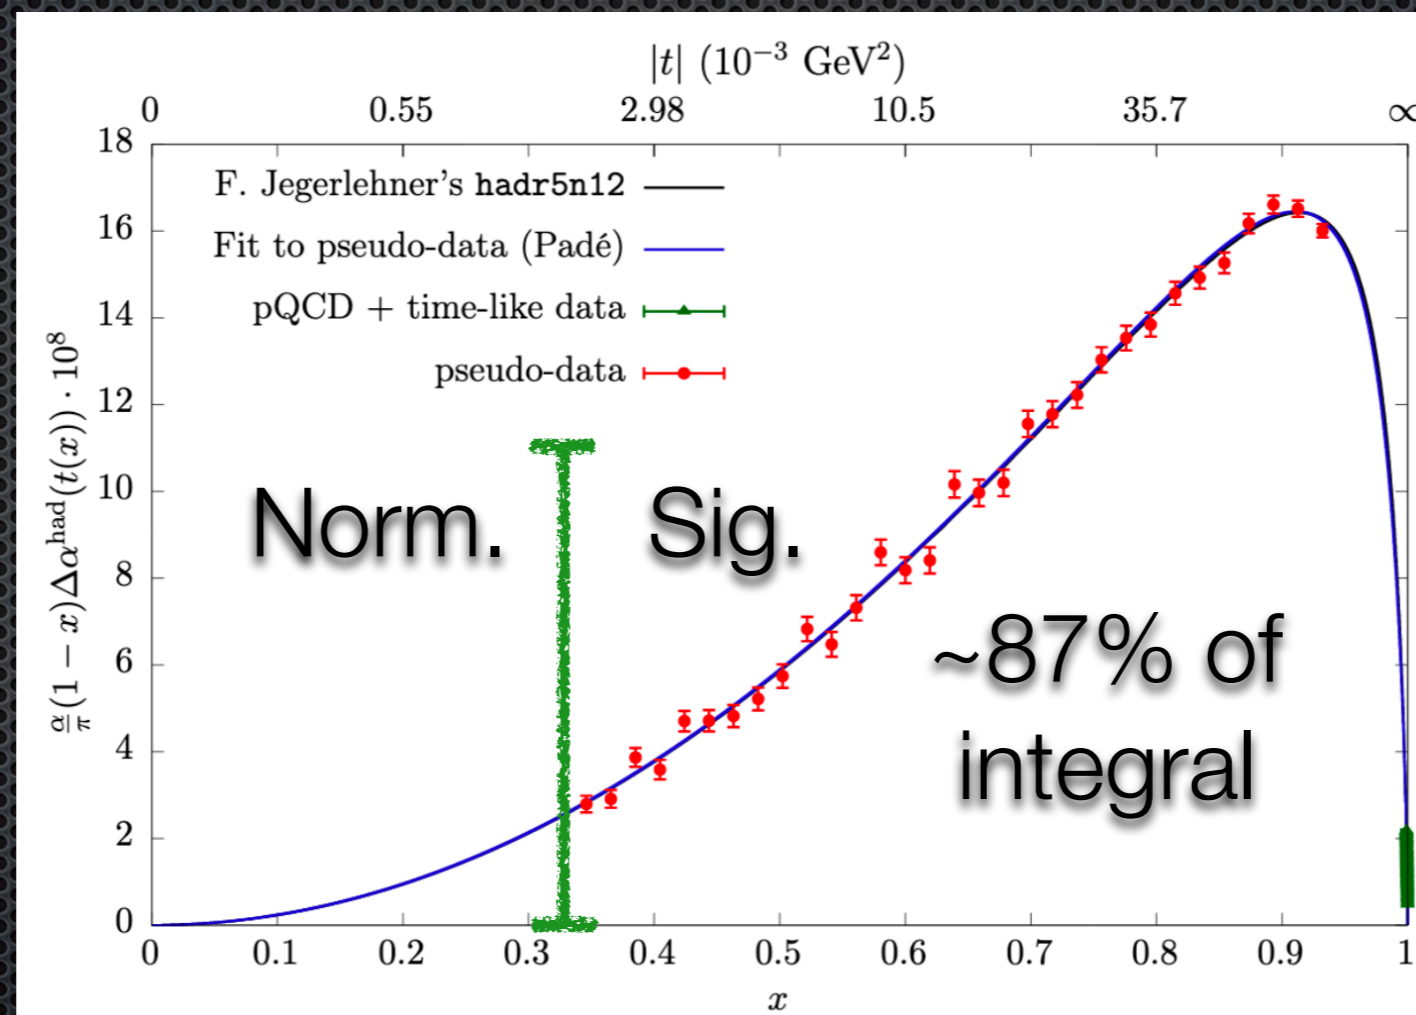

The μ ONE experiment

- Pure t -channel process with $\frac{d\sigma}{dt} = \frac{d\sigma_0}{dt} \left| \frac{\alpha(t)}{\alpha(0)} \right|^2$
- Two body scattering with closed kinematics $E_f^e = m_e \frac{1 + r^2 \cos^2 \theta_e}{1 - r^2 \cos^2 \theta_e}$
- Boosted kin. allows to keep systematics under control

The μ ONE experiment

- Systematics under control: same process for both signal and normalisation region;
- Simulating 2y data taking: 0.3% stat uncertainty on a_{μ}^{H-LO}

The μ ONE experiment

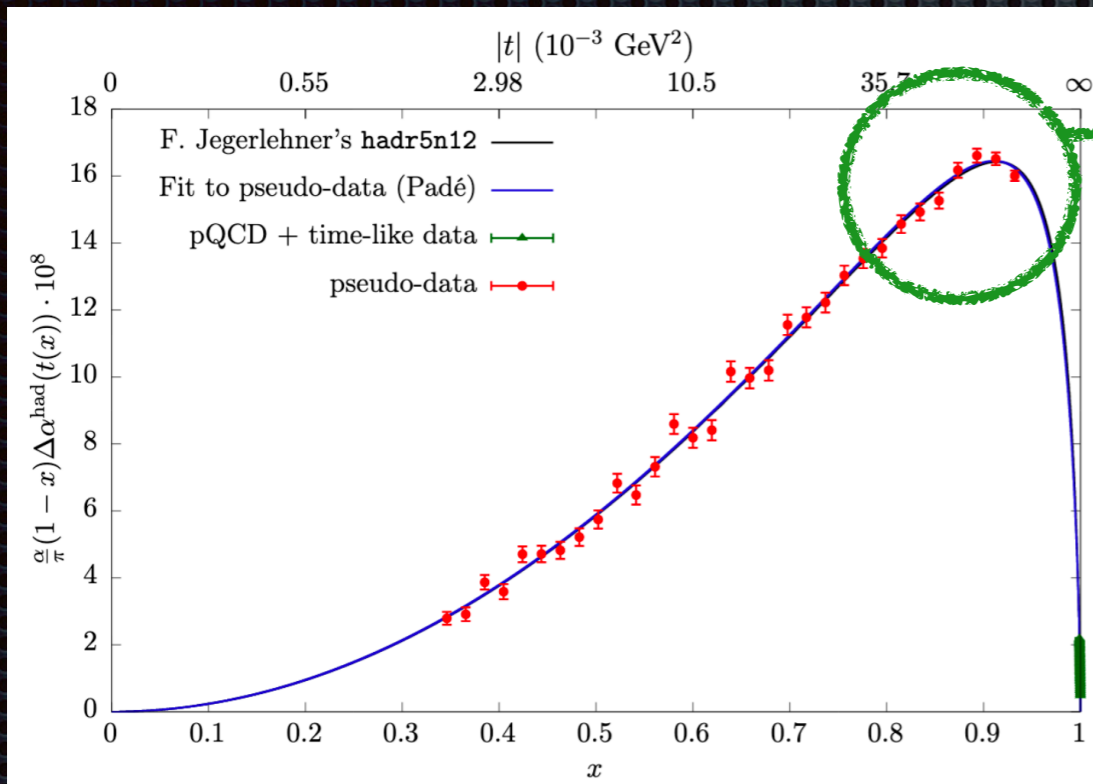

Correlation between electron and muon angles can be exploited to retrieve elastic scattering events.

Signal region for $\theta_e < 10\text{mrad}$ and $E_e > 10\text{GeV}$

- ✦ 60 modules: 1 cm Be target + 3 Si trackers;
- ✦ State of art Si detectors to achieve $\sim 20\mu\text{m}$ resolution;
- ✦ ECAL and muon chamber for particle ID.

Precise measurement of a_{μ}^{H-LO} requires knowledge of signal/norm ratio with **10ppm systematic uncertainty**

- ✦ **Multiple scattering** in thin absorber: need to be known at $\sim 1\%$ (in core region);
- ✦ Beam energy knowledge at 0.8% using BMS spectrometer;
- ✦ Tracking uniformity, alignment and angles reconstruction

Beam tests in October 2017 and April 2018 to understand Multiple Scattering effects and to have a first proof-of-concept of the detector

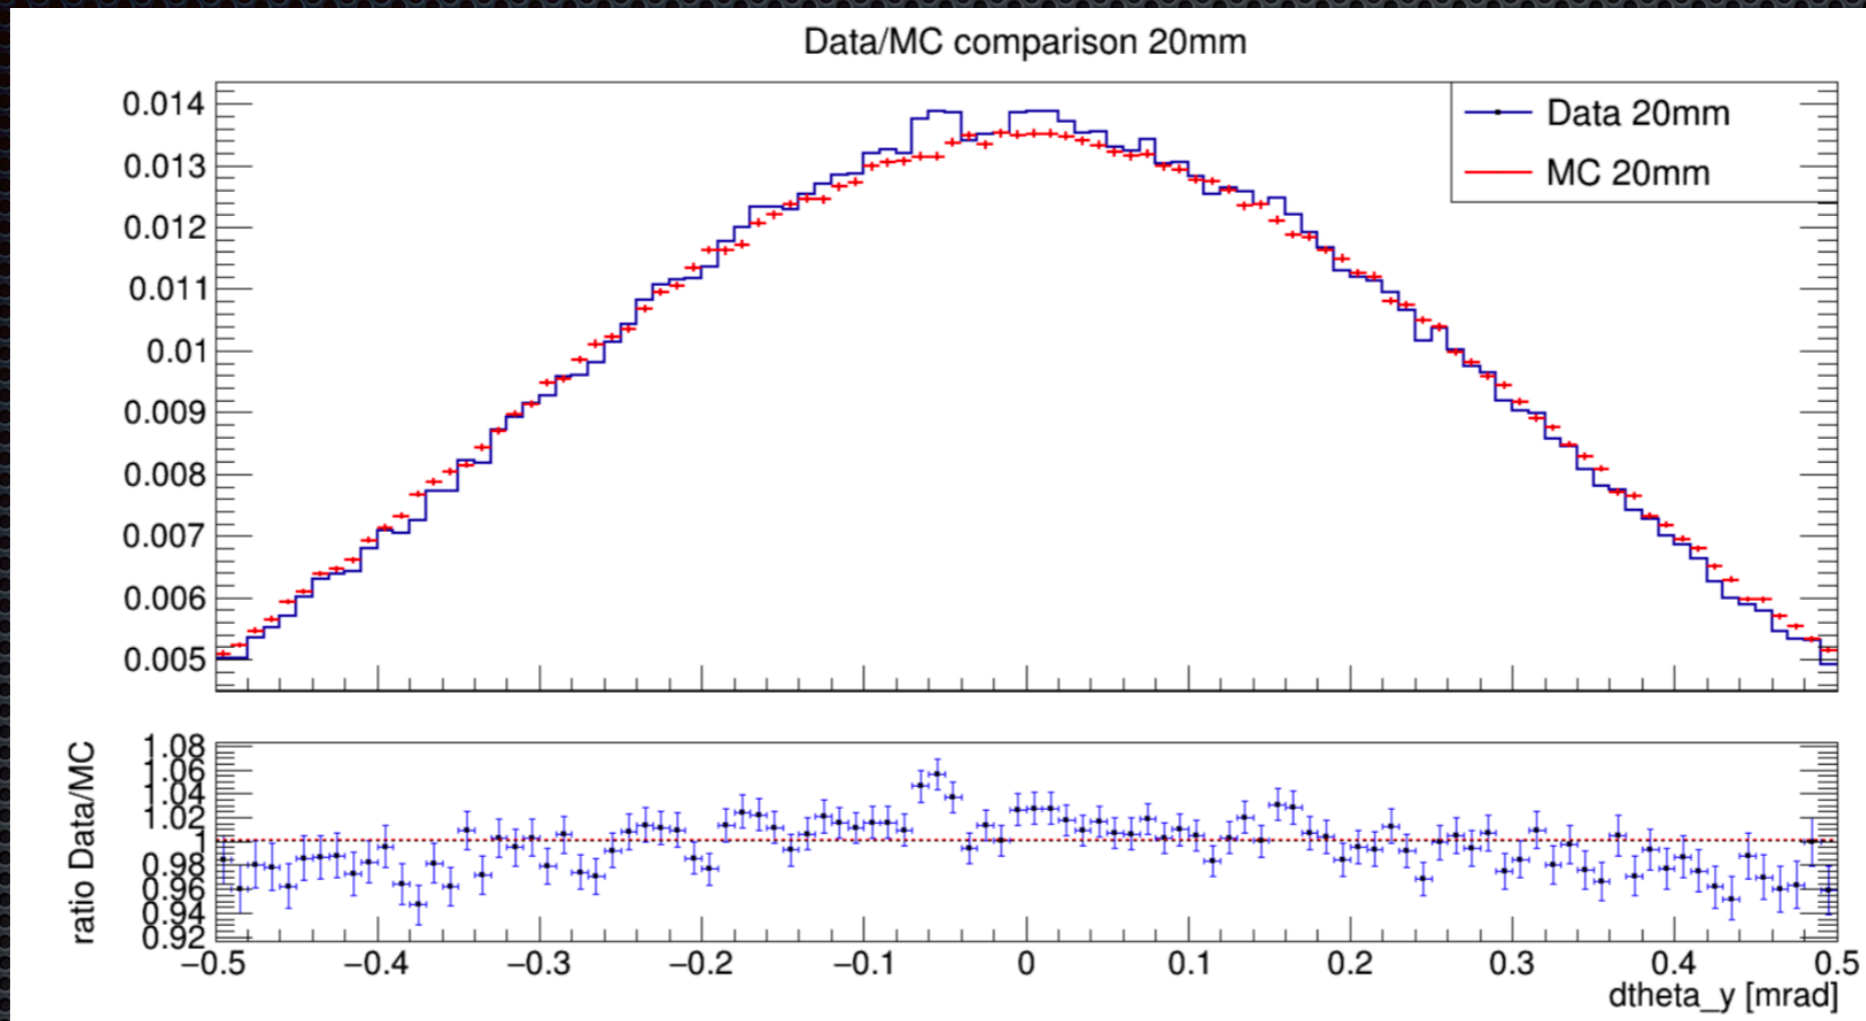

October 2017 beam test @CERN, using UA9 telescope:

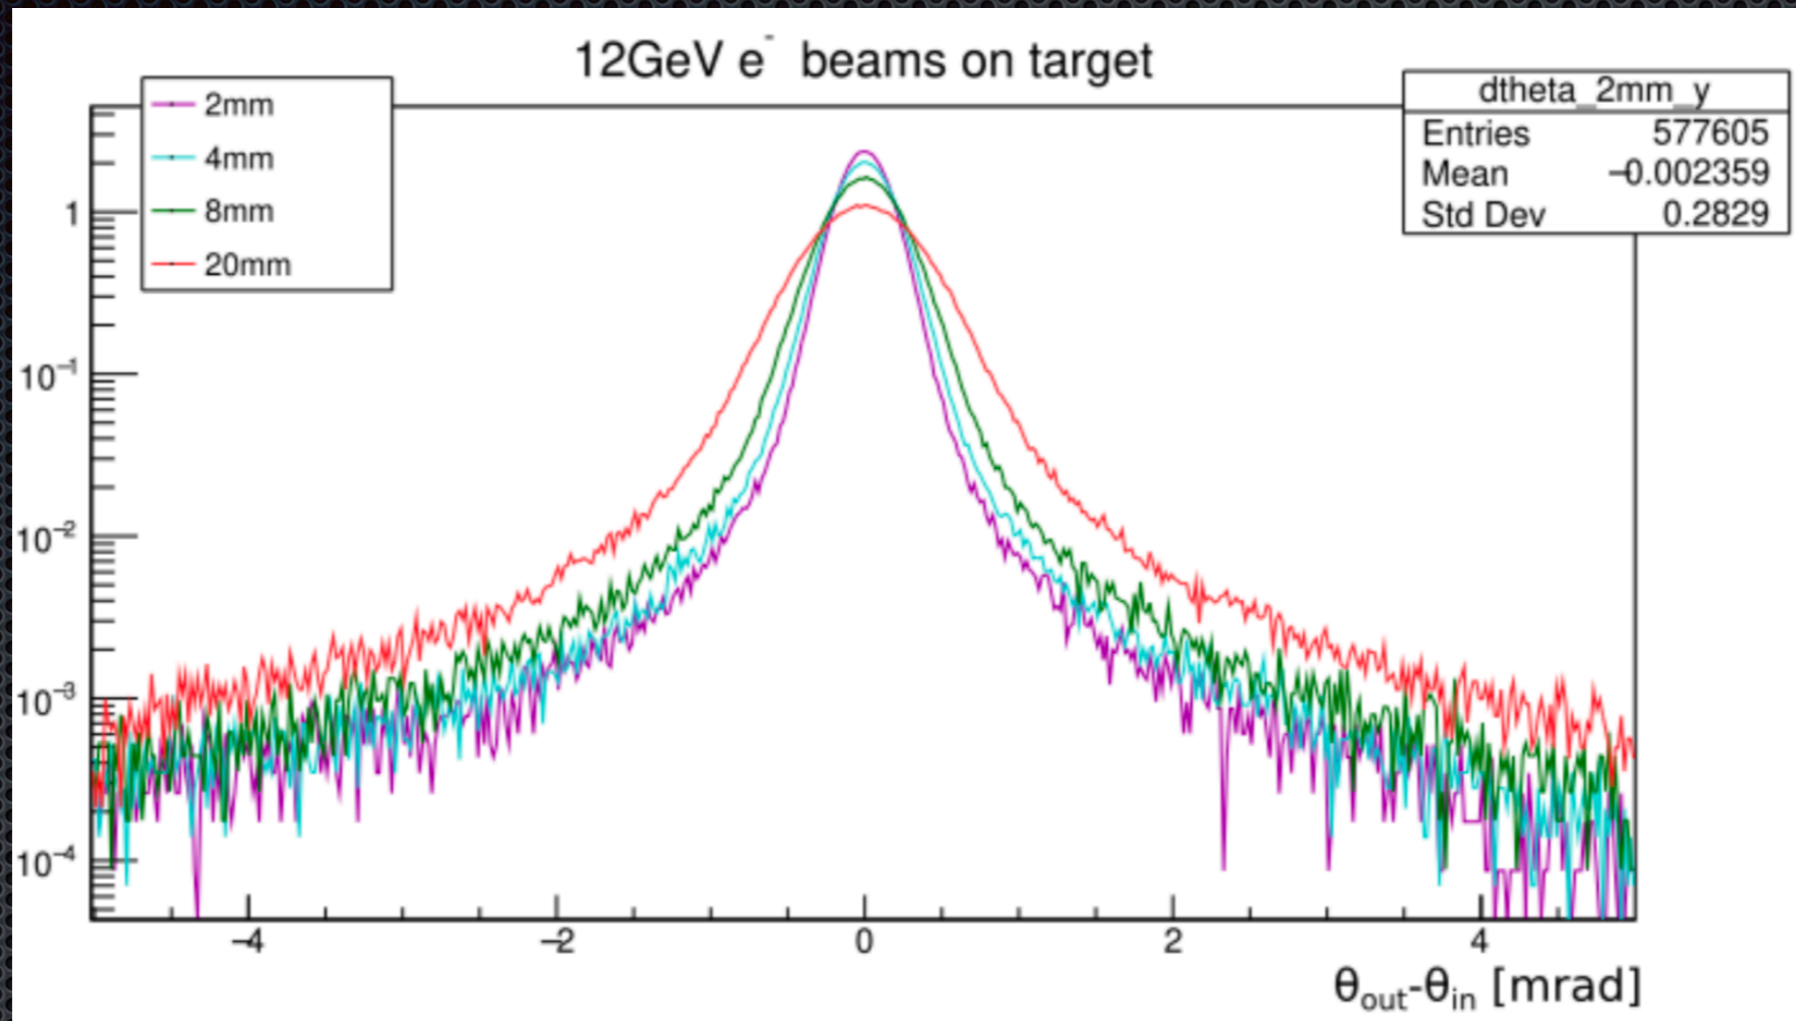

1 module tested: 2 upstream + 3 downstream planes

C, Be targets for 2, 4, 8, 20 mm

12,20GeV e^- beams

- Multiple Scattering increases with target thickness;
- Dedicated Geant4 simulation of the apparatus describes at ~1% data;

😊 : MSC core is gaussian, we can deal with it

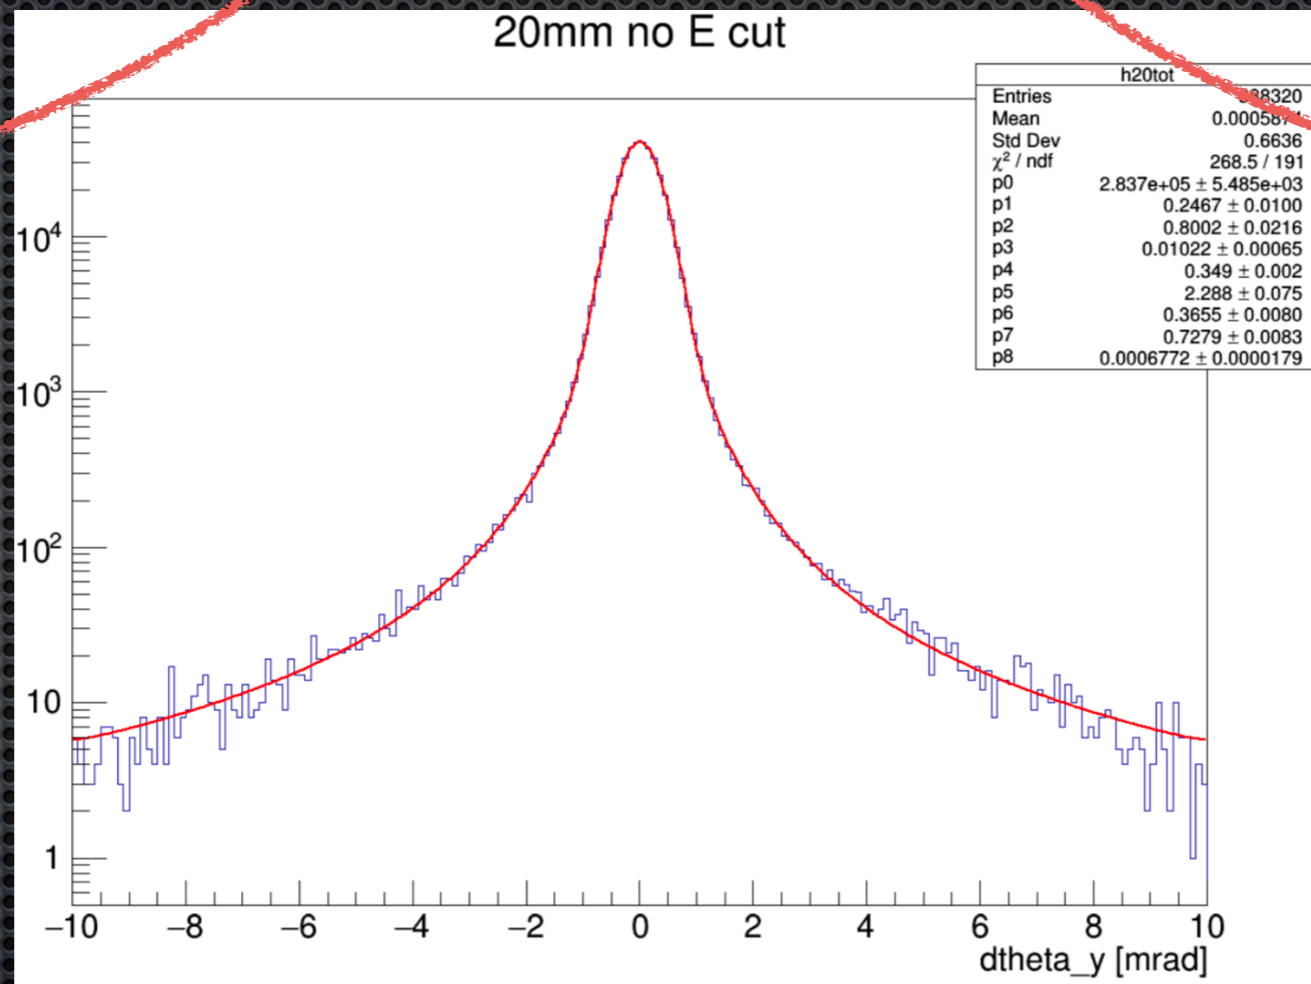

😞 : What do we do with the tails? MSC events end there!

: Describing Multiple Scattering

 : What do we do with the tails? We fit them!

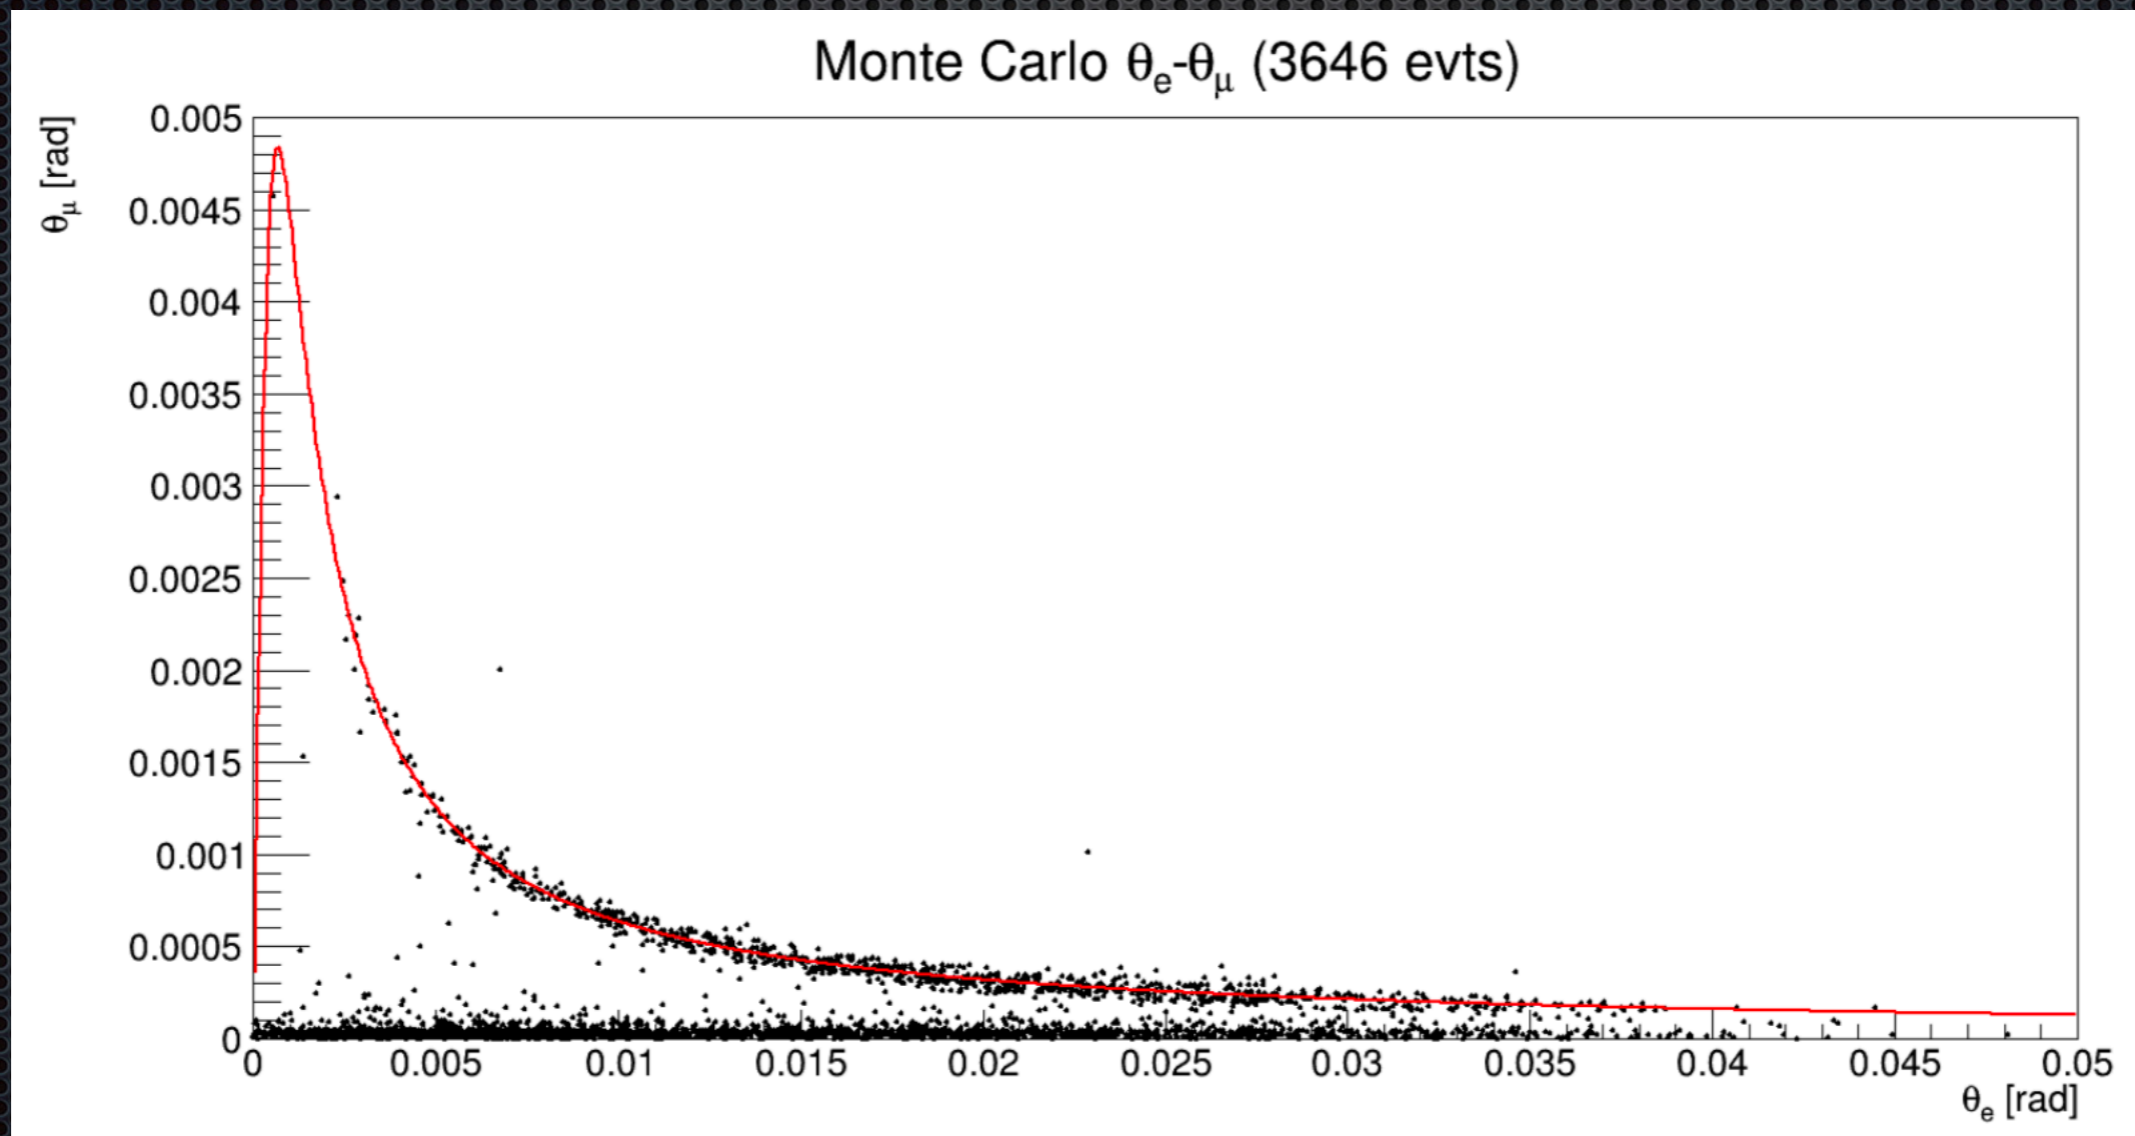

$$f(\theta) = f_{telescope}(\theta) * f_{target}(\theta)$$

Gauss +
t-Student

t-Student

- ✦ Scattered electron and mu from χ^2 minimisation on downstream planes;
- ✦ Delicate to take into account MSC errors.

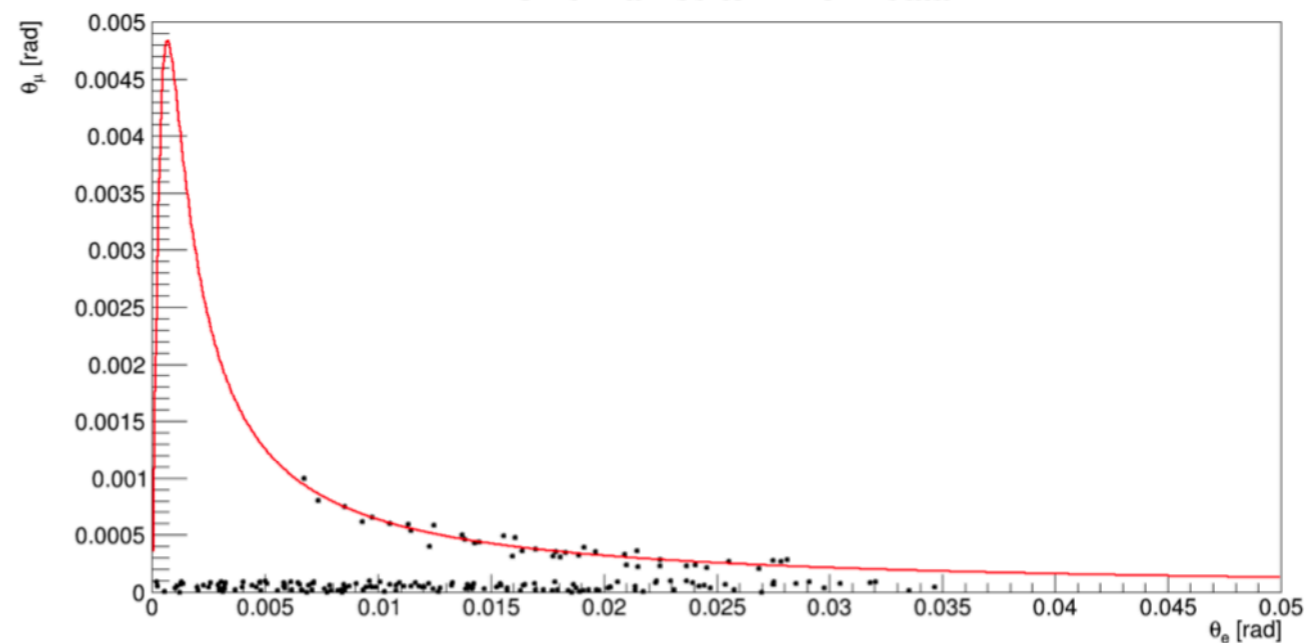

Qualitative good agreement between data and simulation for the reconstruction of elastic scattering events!

θ_e vs θ_{μ}

MC normalized to TB2017 data

: What is the background?

We can use Geant4 - 🙄 - to better understand how the $\theta_e - \theta_\mu$ plot gets populated... most of the background comes from e^+e^- pair production!

: The importance of tracking

In April 2018: new beam test!

u, v planes for discrimination; x,y for tracking

Two targets to measure independently mu-e events;

Si trackers with **40um** (20um in 2017TB);

Larger detector arm, up to **15mrad** full acceptance;

Upstream **BGO-PMT calorimeter** for PID.

: The importance of tracking

In April 2018: new beam test!

Two stations

Worse Si trackers (40um res), **larger** acceptance (12mrad)

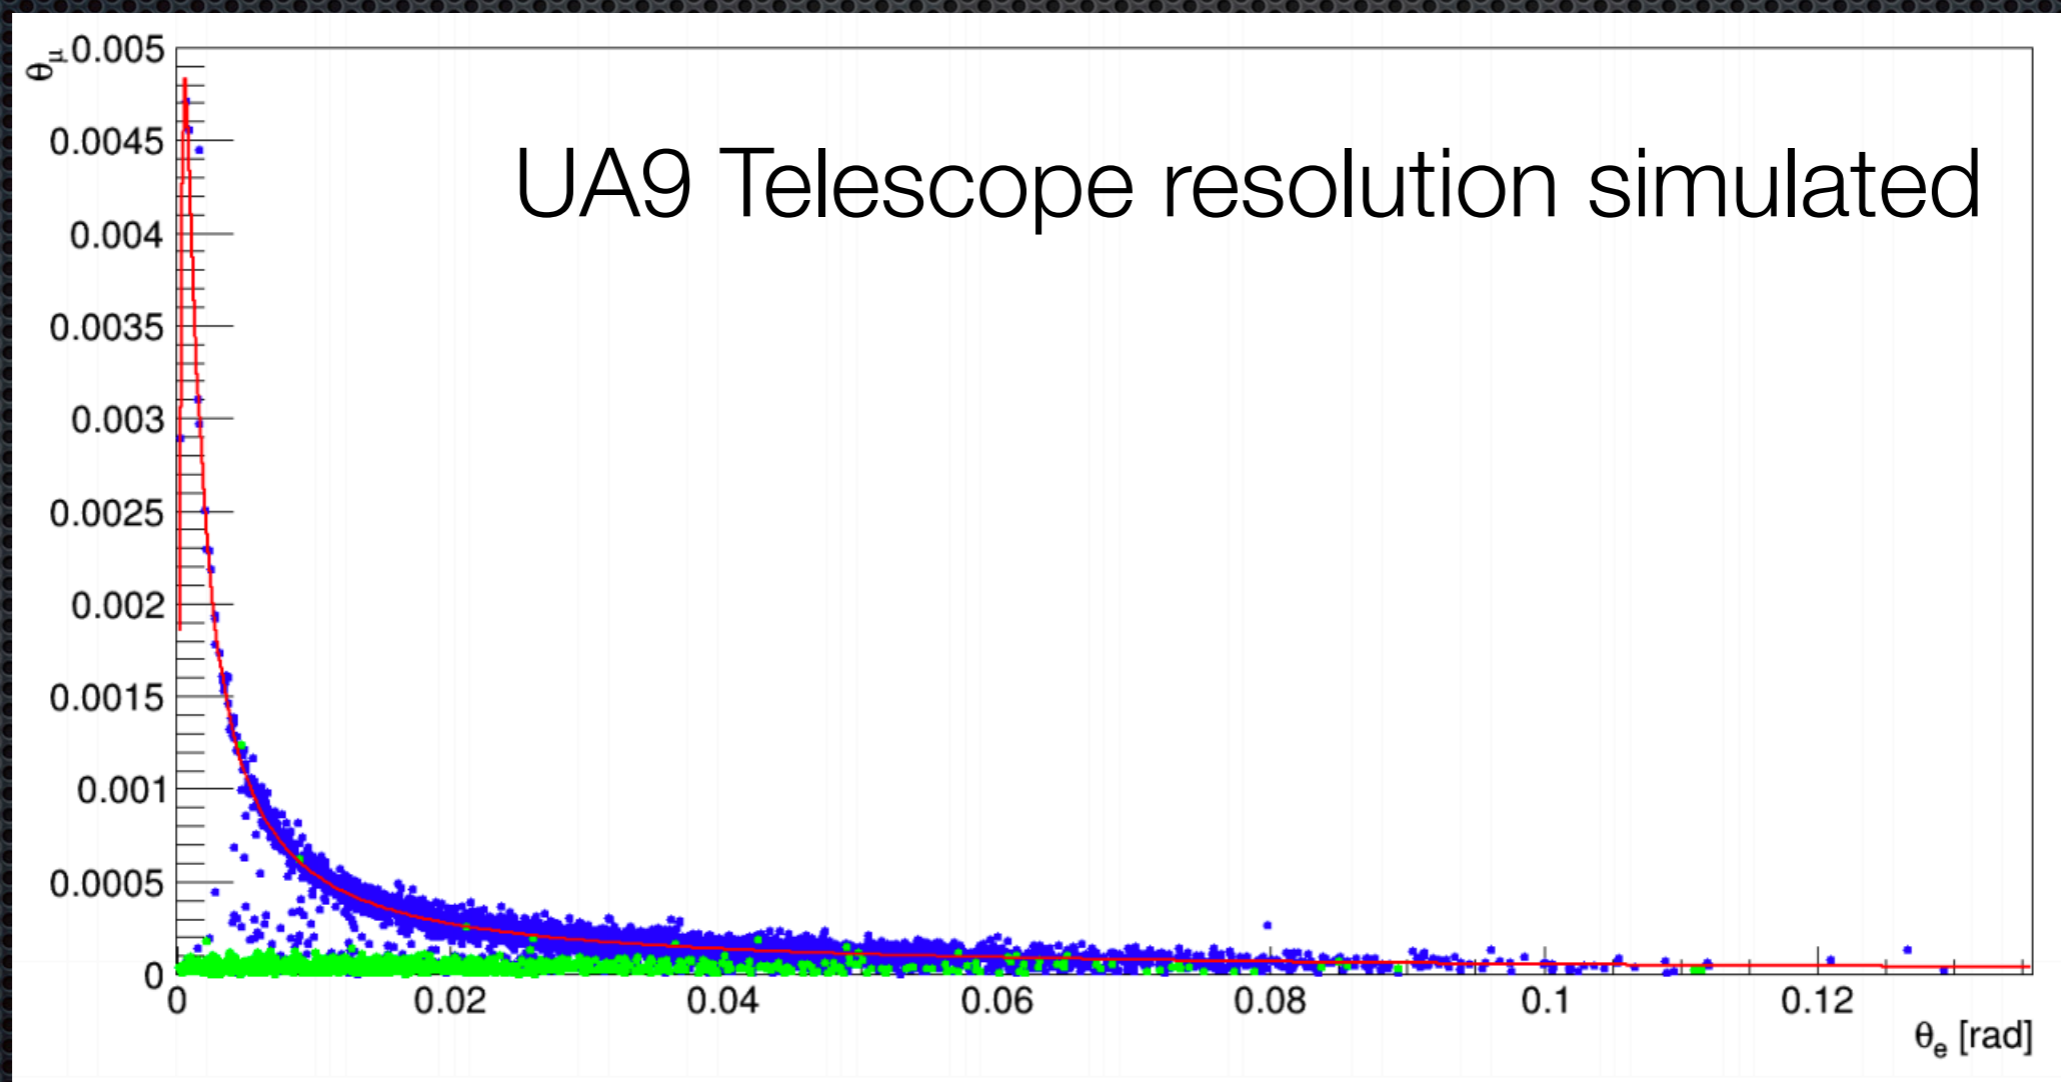

: The importance of tracking

In April 2018: new beam test!

Two stations

Worse Si trackers (40um res), **larger** acceptance (12mrad)

Conclusions

- $(g - 2)_\mu$ discrepancy between E821 and SM at $\sim 4\sigma$
 - > Extremely interesting portal to BSM physics
- H-LO contribution is the dominant source of theoretical uncertainty:  aims to nail it down;
 - > LOI submitted in 2019; First pilot run 2021;
 - > Possible start of physics run in 2023.
- Delicate experiment aiming to reach **ppm** precision: very challenging but very stimulating!
