Table of contents

- 1 Introduction
- 2 Baryons
 - Single-flavour baryons
 - Triple-charm baryons
 - Exotic baryons
- 3 Mesons
 - Heavy quarkonia
 - Hybrid mesons
 - Multiquark mesons
- 4 Further exotics
- 5 Conclusion

Introduction

Encouraging recent results

- new states seen in high-energy experiments,
- for instance, $D_{s,J}$, $X(3872)$, $\eta_c(2S)$
- many new single-charm or single-beauty baryons
- while low-energy experiments sometimes gave misleading results (pentaquarks)
- even **complex** and **fragile** structures, such as antideuterium produced at high energy

Less encouraging

- spectroscopy and flavour program also foreseen at heavy-ion facilities (RHIC)
- see, e.g., BNL Workshop, May 2002
- but never given enough priority in detector tuning and in analysis

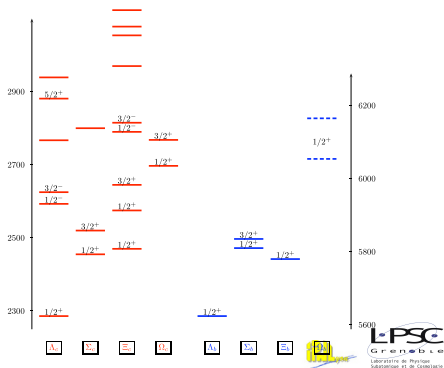

New baryons

Single-flavour baryons

Many new states, in particular at CLEO. At present, 34 charmed baryons and 7 beauty baryons are known.

Hope: Understanding light-quark dynamics from charmed baryons, before light baryon resonances?

Problems

New baryons

Double-charm baryons

- (ccq) and b analogues (bcq) and (bbq)
- Tentatively seen by SELEX
- Not seen elsewhere, in particular at BaBar,
- Combine the **charmonium-like** dynamics (non-relativistic limit of QCD)
- With the **D -like** dynamics (ultra-relativistic regime)
- In a single hadron, with also interesting **weak-decay** properties

New baryons

Triple-charm baryons

- (*ccc*) and *b* analogues (*bcc*), (*bbc*) and (*bbb*)
- *The ultimate goal of baryon spectroscopy* (Bjorken)
- To probe the real three-quark interaction of QCD, independently of light-quark complications
- The baryon analogue of heavy quarkonium
- Large binding effects in weak decay

New baryons

Exotic baryons

- $QQQg$, on the same footing as the more advertised hybrid mesons ($Q\bar{Q}g$)
- but with the same quantum numbers as (QQQ)
- Heavy pentaquarks (1987 vintage, Lipkin, Gignoux et al.) ($\bar{Q}qqqq$)
- Predicted on the same (fragile) chromomagnetic mechanism as Jaffe's H dibaryon

Mesons

Heavy quarkonia

- Missing ($b\bar{b}$) states, e.g., the $\eta_b(nS)$ ($n = 1$ seen reported recently)
- ($b\bar{c}$) spectroscopy, probing flavour independence
- ($b\bar{c}$) **decays**, in particular binding effect, role of c vs. b , etc.
- **Production** mechanisms

Mesons

Hybrid mesons

- **Predicted** since the late 70's, on the basis of models (Gilles and Tye (1978), Mandula and Horn (1978), and Hasenfratz, Horgan, Kuti and R. (1980), etc.
- **Confirmed** in more elaborated approaches, e.g., Lattice QCD
- **Better seen in heavy quarkonia?** (cleaner background of “ordinary states”)
- Possibility of **exotic J^{PC}**
- **Already** some speculations for $X(3872)$, $X(3940)$ or $Y(4260)$

Mesons

Multiquark mesons

- **Very old problem.** In particular for light scalar mesons. Some of them often described as S-wave ($qq\bar{q}\bar{q}$) rather than P-wave ($q\bar{q}$)
- For light quarks and antiquarks, **chromomagnetism** is a possible source of stability (or metastability) against dissociation into two mesons,
- Heavy quarks more sensitive to **chromoelectric** forces, hence new type of configurations become favoured
- An example, on which all theorists agree is ($QQ\bar{q}\bar{q}$) (double-flavour mesons), which should be *below* the threshold ($Q\bar{q} + (Q\bar{q})$) if the mass ratio Q/q is large enough
- Same mechanism by which in **atomic physics** (ppe^-e^-) is more stable than ($e^+e^+e^-e^-$): the 4-body compound benefits of the heavy-heavy binding, and this effect is not active in the threshold.

$(QQ\bar{q}\bar{q})$ Mesons

Recent developments

- Favourable heavy–light asymmetry confirmed by QCD sum rules
- A better treatment of confinement, as suggested by lattice QCD, gives a more realistic (and much more difficult to handle) potential

gives more attraction than the additive ansatz used previously.

- Similarly $(\bar{q} q_1 q_2 q_3 q_4)$ found to be stable if q_i different

Further exotics

- Four-quark mesons sometimes described as meson–meson **molecules**
- Bound by **nuclear forces** (Törnqvist, Swanson, Ericson & Karl, Manohar, etc)
- Other states predicted in this approach, in particular **bound states of charm baryons**
- For instance $(ccq) - (ccq)$ (Riska & Julia-Diaz)

Conclusion

- LHC can contribute to **confinement** and **flavour** physics
- Many states await discovery
- Some predictions are fragile and controversial
- Other predictions are more solid, e.g. ($QQ\bar{q}\bar{q}$)
- LHC offers a good opportunity
- If a reasonable fraction of efforts devoted to this physics
