

Fermi
Gamma-ray Space Telescope

Sources detected by the *Fermi* Large Area Telescope

Jean Ballet (CEA/DSM/IRFU/SaP)

on behalf of the Fermi LAT Collaboration

The GeV and TeV sky
LLR, September 17, 2009

The Observatory

Spacecraft Partner:
General Dynamics

Large Area Telescope (LAT)
20 MeV - >300 GeV

Gamma-ray Burst Monitor (GBM)
NaI and BGO Detectors
8 keV - 40 MeV

KEY FEATURES

- **Huge field of view**
 - LAT: 19% of the sky at any instant; in sky survey mode, expose all parts of sky for ~30 minutes every 3 hours.
 - GBM: whole unocculted sky at any time.
- Huge energy range, including largely unexplored band 10 GeV - 100 GeV.
 - Total of >7 energy decades!**
- Large leap in all key capabilities. Great discovery potential.

LAT Collaboration – an AP-HEP partnership

5 years operations (+ 5 years)

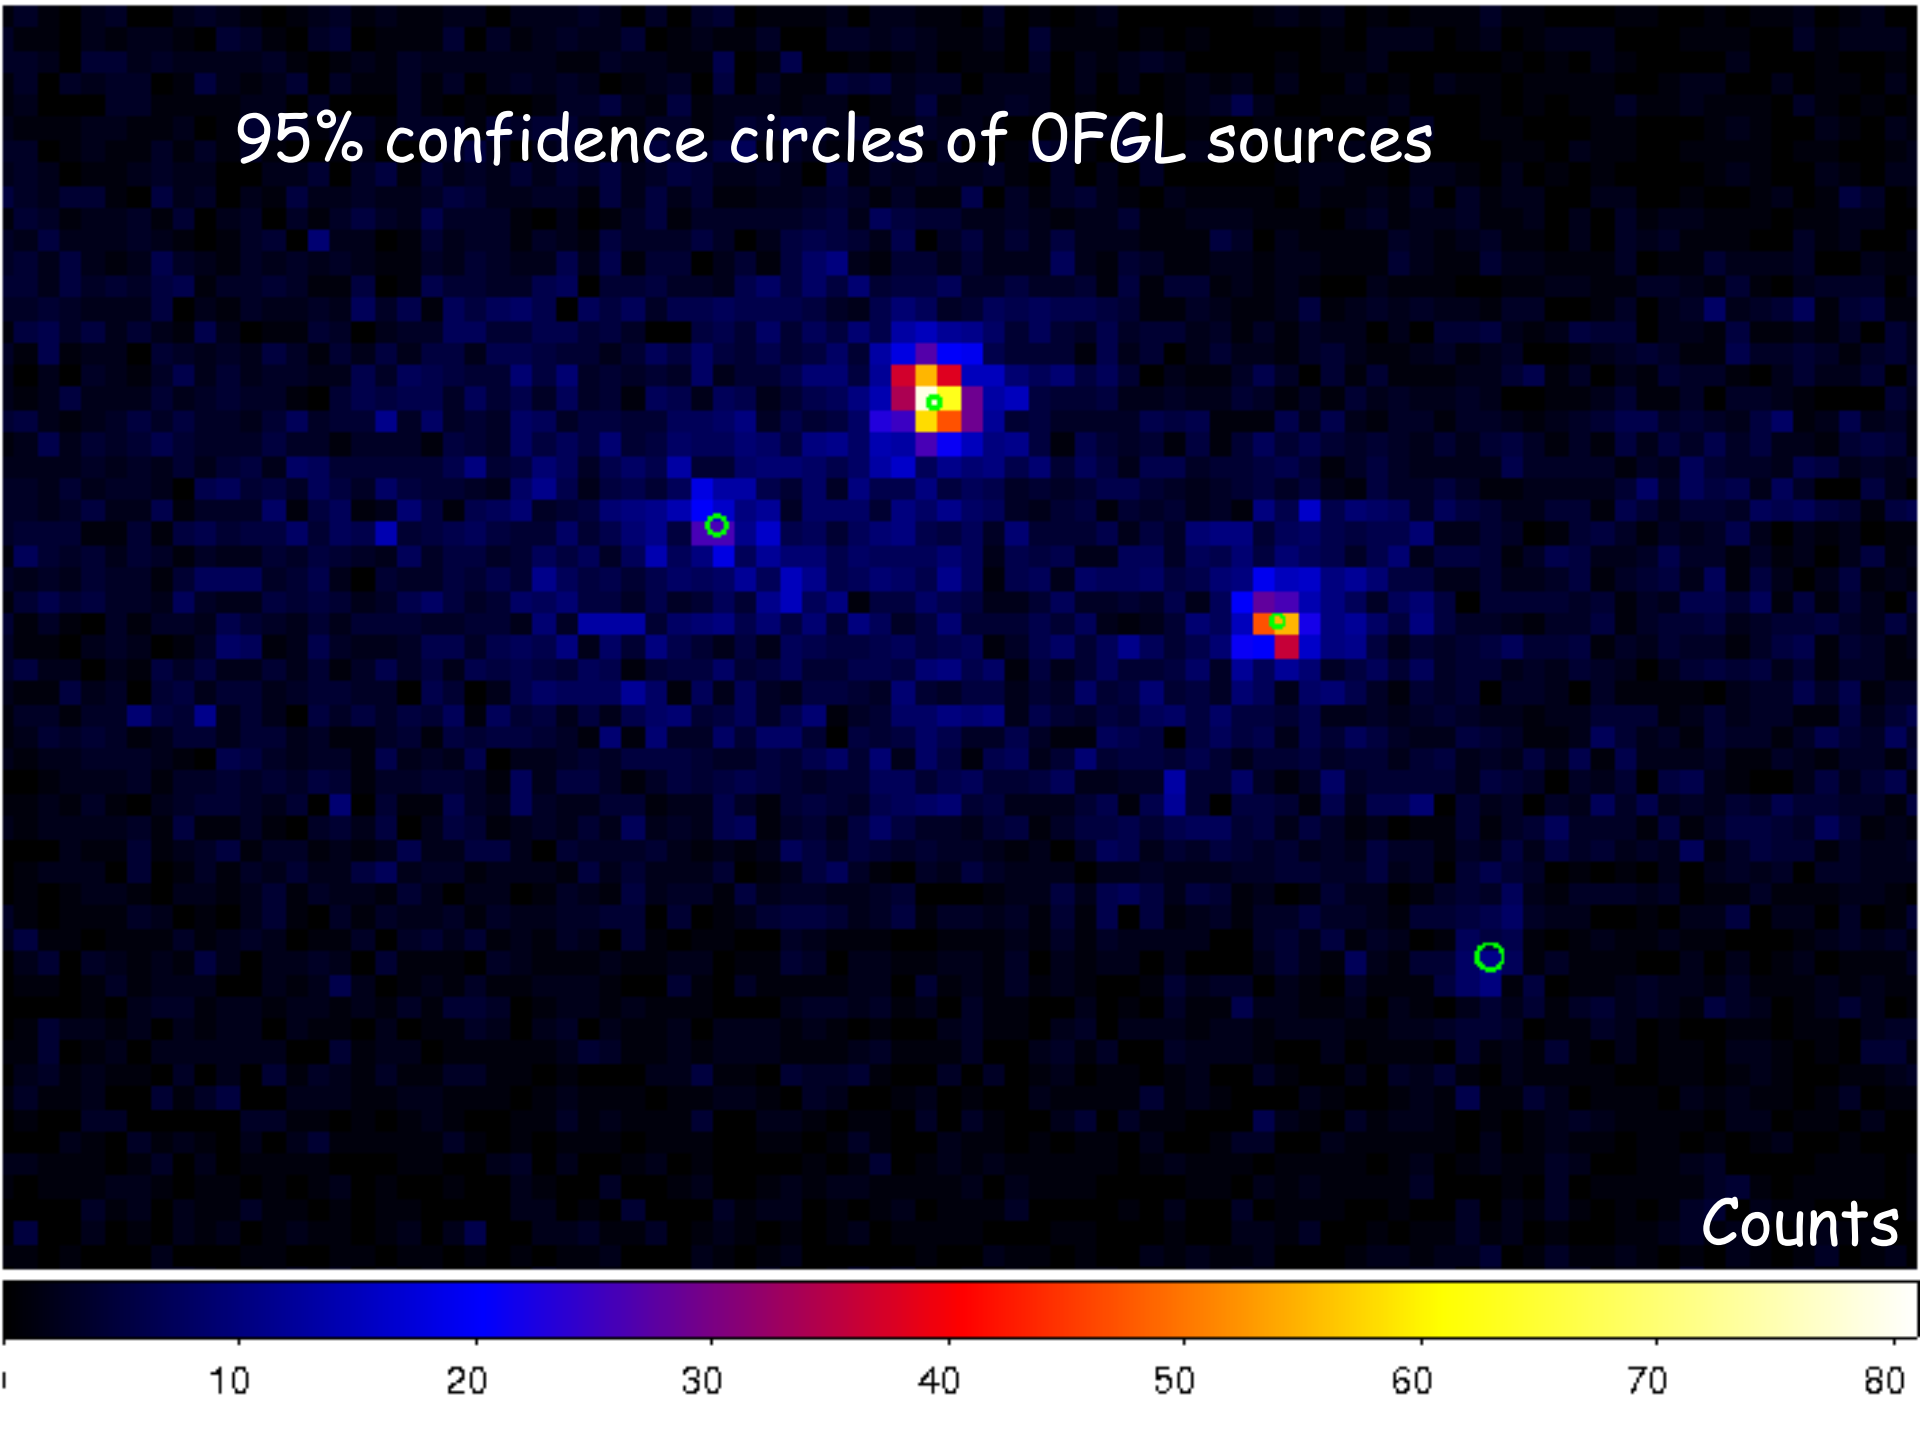

The LAT Bright Source List (0FGL)

- 1.8 M events above 200 MeV with current cuts over 3 months
- Wavelet analysis (peak detection) for source detection
 1. Front events > 200 MeV + Back events > 400 MeV
 2. Front events > 1 GeV + Back events > 2 GeV
- **Large overlap at low energy** → Maximum likelihood analysis for locations, source significance, fluxes below and above 1 GeV, and variability information.
- Confidence level greater than **10 σ** over 3 months. **Not uniform** - sources near the Galactic plane must be brighter because of the strong diffuse background
- Associations with known sources

The Point Spread Function is key to source detection and identification

95% confidence circles of OFGL sources

Exposure map

- ❑ Data used are the first three months of all-sky scanning data, Aug. - Oct. 2008. Total live time is 7.53 Ms
- ❑ Scanning scheme makes exposure map very uniform (SAA creates 25% North-South asymmetry)

Equivalent on-axis observing time, Galactic coordinates, Aitoff projection

Sensitivity map

- ❑ Structure is mostly that of the interstellar medium
- ❑ Below 10^{-7} ph/cm²/s outside the Galaxy ($|b| > 10^\circ$)

10^{-7} ph/cm²/s

Flux > 100 MeV required to reach 10σ over 3 months for average $E^{-2.2}$ spectrum

Galactic coordinates, Aitoff projection

205 LAT Bright Sources

Front > 200 MeV, Back > 400 MeV

Crosses mark source locations, in Galactic coordinates. 1/3 at $|b| < 10^\circ$.
Only 60 clearly associated with 3EG EGRET catalog. The sky changes!

9 months data

Front > 200 MeV, Back > 400 MeV

Galactic coordinates, Aitoff projection, SQRT color scale

Source association

- 2/3 of the sources at $|b| > 10^\circ$, mostly AGN
- Only 9 unassociated outside the plane
- Globular cluster 47 Tuc (plenty of ms pulsars), LMC / 30 Dor (diffuse)

Abdo et al. 2009
ApJS 183, 46

○ Unassociated	× AGN	◇ Pulsar
+ X-ray binary	▽ Globular cluster	

Source association 2

- ❑ Most associated sources in the Galaxy are pulsars
- ❑ Many unassociated sources in the inner regions of the Galaxy (circles)

Close-up on the Galactic ridge

The *Fermi* LAT First Source Catalog (1FGL)

Improvements over the Bright Source List (0FGL)

- Based on data accumulated over 11 months
- More accurate calibration
- More precise model for Galactic diffuse (public since August 25)
- Similar (but more inclusive) detection methods
- Similar maximum likelihood analysis, but more information (flux in five energy bands and per month, average spectral index)
- Minimum confidence level down to 5σ . Will contain more than 1000 sources
- Similar association process, expect smaller association rate going to fainter sources

Expected in October 2009

Pulsars

Many categories of sources (blazars, GRBs, binaries, PWN, SNRs) will be covered in other talks

Pulsars are a major category of sources in the GeV band

Several EGRET unidentified sources turn out to be pulsars

Not bright in TeV range

Discovery of First Gamma-ray-only Pulsar

A radio-quiet, gamma-ray only pulsar, in Supernova Remnant CTA1

Quick discovery enabled by

- large leap in key capabilities
- new analysis technique (Atwood et al 2006)

- Spin-down luminosity $\sim 10^{36} \text{ erg s}^{-1}$, sufficient to supply the PWN with magnetic fields and energetic electrons.
- The γ -ray flux from the CTA 1 pulsar corresponds to about 1-10% of E_{rot} (depending on beam geometry)

Age $\sim (0.5 - 1) \times 10^4$ years
Distance $\sim 1.4 \text{ kpc}$
Diameter $\sim 1.5^\circ$

Pulsar emission model

In the simplest model, the emission should depend on 4 parameters: spin period, magnetic field, magnetic dipole inclination, and viewing angle

- luminosity derived from rotational energy

$$E_{\text{rot}} = \frac{1}{2} I \Omega^2$$

$$\dot{E} = - B^2 R^6 \Omega^4 / c^3$$

- derived parameters:

rotational age : $\tau = \Omega / 2\dot{\Omega}$

B field: $B = 3.2 \times 10^{19} (P\dot{P})^{1/2} \text{ G}$

spin-down power: $L = I\Omega\dot{\Omega}$

First *Fermi* view of the Vela Pulsar

Remarkably sharp peaks; features to ~0.3ms.

Turns nearly completely off between the double pulses.

Vela Pulsar – Phase-averaged SED

$$N(E) = N_0 E^\Gamma e^{-(E/E_c)^b}$$

Consistent with $b = 1$
(simple exponential)

$$\Gamma = -1.51^{+0.05}_{-0.04}$$

$$E_c = 2.9 \pm 0.1 \text{ GeV}$$

$b = 2$ (super-exponential)
rejected at 16.5σ

No evidence for magnetic
pair attenuation –
Near-surface emission
ruled out

Millisecond pulsars

Old pulsars in a binary accelerated by accretion from the companion
 Very fast rotators but low magnetic field

Fermi sees those
 with high 'spin-
 down flux'

$$\dot{E}_{sd} / d^2$$

The nearby
 population

The Pulsing Sky

25 radio-loud PSRs (7 ms)
13 radio-quiet PSRs

Up to 46 pulsars now

Fermi Pulsar Detections

- New pulsars discovered in a blind search
- Millisecond radio pulsars
- Young radio pulsars
- Confirmed pulsars seen by Compton Observatory EGRET instrument

Pulses at
 $1/10^{\text{th}}$ true rate

Radio follow-up

Radio detection of LAT PSRs J1741-2054 and J2032+4127:
no longer just gamma-ray pulsars (Camilo et al., accepted in ApJ)

All phases
Cygnus region

Off-pulse

On-pulse – Off-pulse

Conclusions

- CGRO/EGRET found only 31 sources above 10σ in its lifetime, Fermi/LAT found 205 in the first 3 months
- Typical 95% error radius is less than 10 arcmin.
- About 1/3 of the sources show definite evidence of **variability**.
- Over half the sources are associated positionally with **blazars** (85% associations outside the plane, up from 60% with EGRET).
- 37 sources in 0FGL have no obvious associations with known gamma-ray emitting types of astrophysical objects.
- 46 **pulsars** are identified by gamma-ray pulsations (up from 6).
- 3 very bright **γ -ray bursts**, several fainter ones.
- 2 high-mass **X-ray binaries** (LSI +61 303 and LS 5039)
- Several **PWNe and SNRs** (W28, W44, W51C, IC443)
