Liquid Xenon Detector in 2021 run

Run for 2022 : Annealing of MPPCs

Summary

Charged Lepton Flavor Violation

- In quark and neutrino (neutral lepton) sector, the flavor violates in SM+ ν mass

- Some theories BSM predict flavor violation in the charged lepton sector
 - In the Standard Model, it is practically prohibited : $\text{Br}(\mu \rightarrow e\gamma) = 10^{-54}$
 - In BSM, $\text{Br}(\mu \rightarrow e\gamma) \sim O(10^{-14})$ is predicted : large enough to search

- Signal : Gamma-ray and positron with 52.8 MeV ($=m_{\mu}/2$)

back-to-back
the same timing

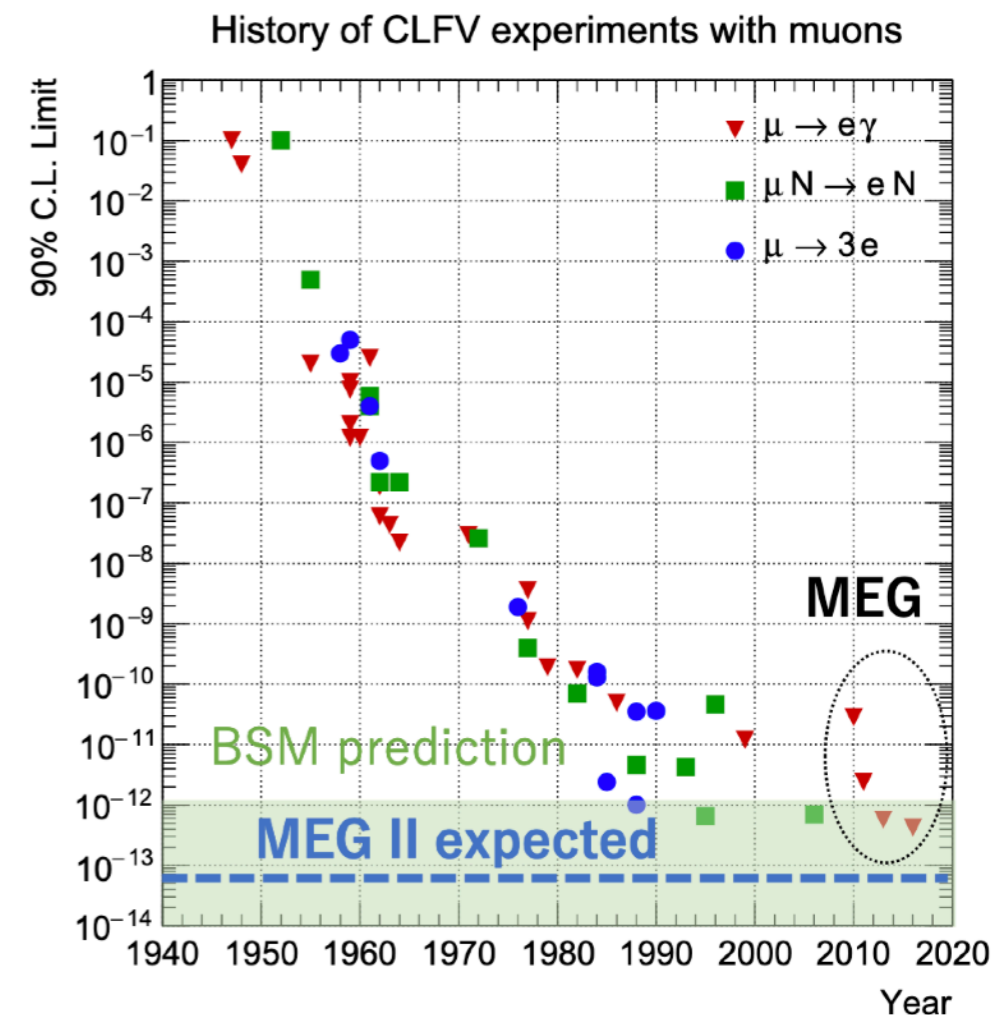

Possible diagram
in SUSY-GUT scenario

- $N_{\text{signal}} \propto [\text{beam rate}] \times [\text{time}]$
- $N_{\text{BG}} \propto [\text{beam rate}]^2 \times [\text{time}] \times [\text{Detector resolutions}]$
- Good resolutions (energy, timing) are required
- DC beam is prefer than AC (pulsed) beam

MEG II experiment

- MEG II experiment aims to search for charged lepton flavor violation : $\mu^+ \rightarrow e^+ \gamma$
- with higher sensitivity by one order of magnitude compared to the MEG
- Consists of LXe detector for γ -ray, drift chamber & timing counter for e^+
- Engineering run and physics run with full number of readout channels were conducted in 2021

MEG II experiment

Run in 2021

Liquid Xenon Detector in 2021 run

Run for 2022 : Annealing of MPPCs

Summary

Timeline in 2021

Assigned beam time

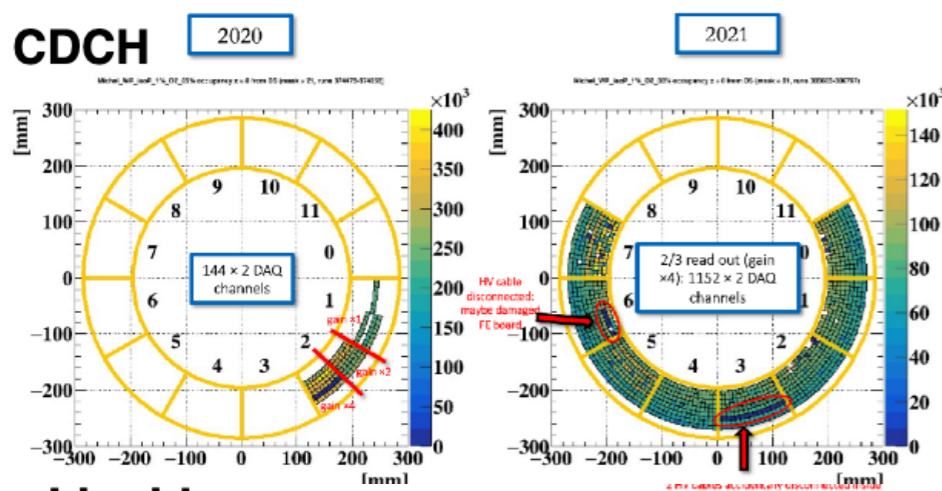

Sub-detector preparation with full channel readout

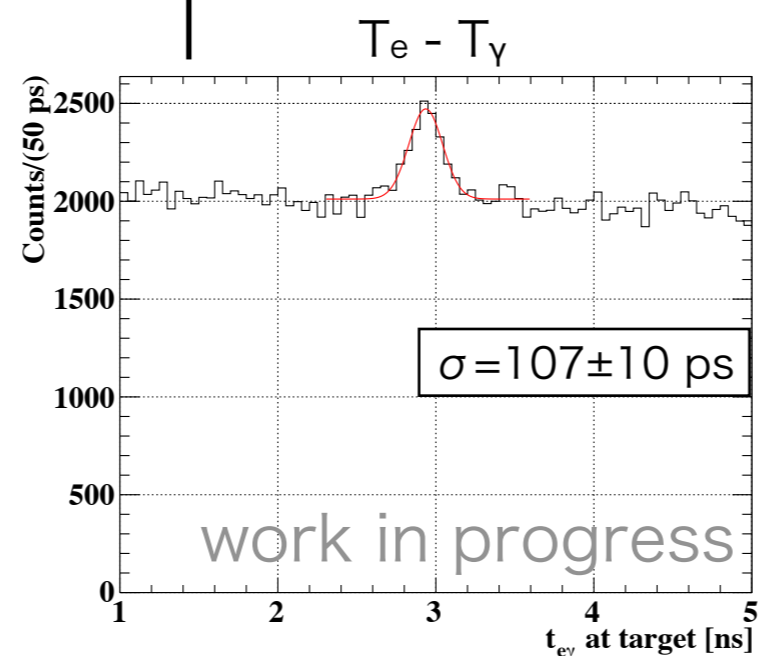

Trigger setup

Physics run

Calibration run with pion CEX

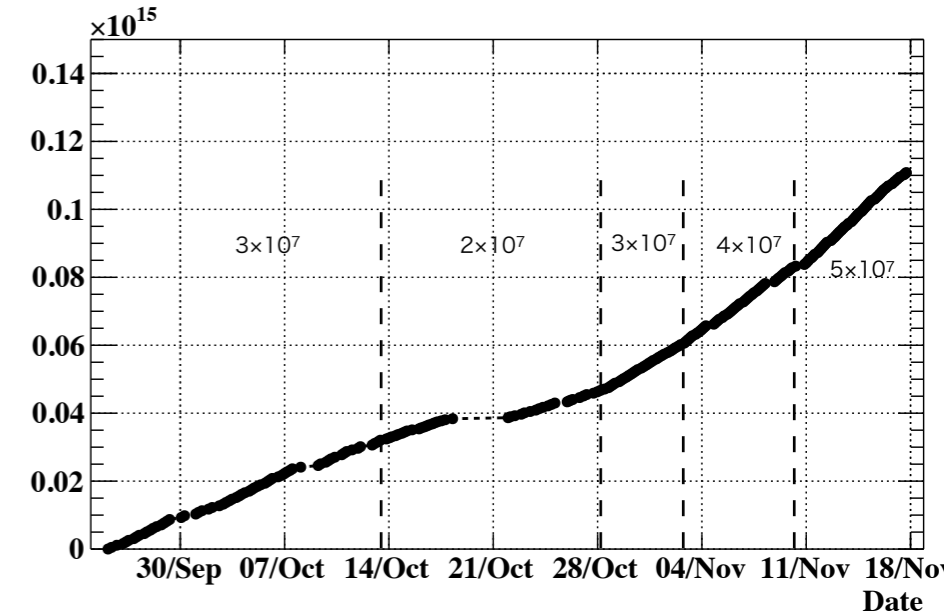

Liquid xenon

Coincidence events between γ and e are obtained
 : Radiative Muon Decay
 $\mu \rightarrow e \nu \bar{\nu}$
 \rightarrow Trigger works as expected

Period : 25th Sep. — 17th Nov.
 Stopped muon in target : $8e+13$

MEG II experiment

Run in 2021

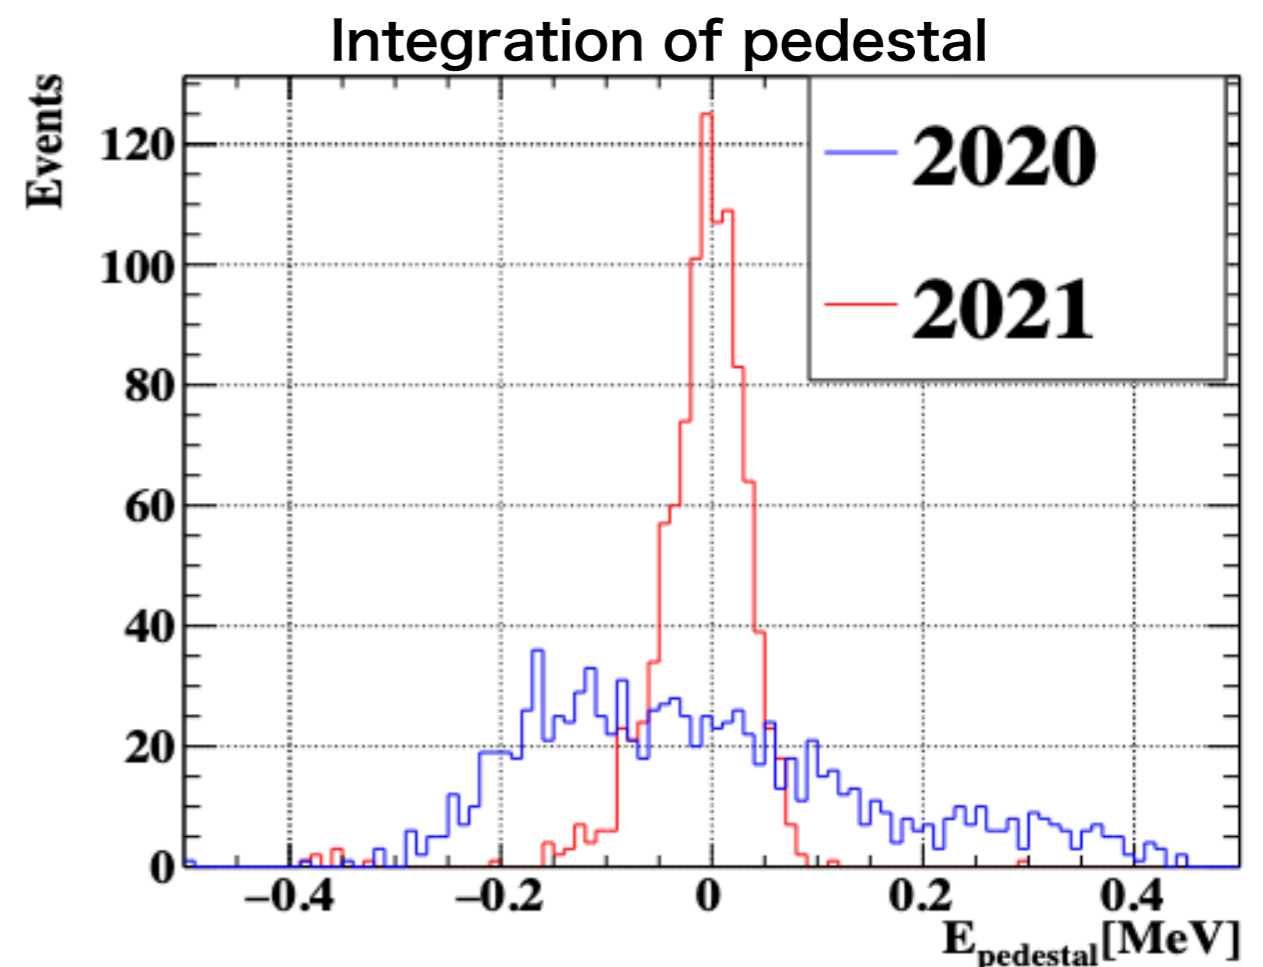

Liquid Xenon Detector in 2021 run

Run for 2022 : Annealing of MPPCs

Summary

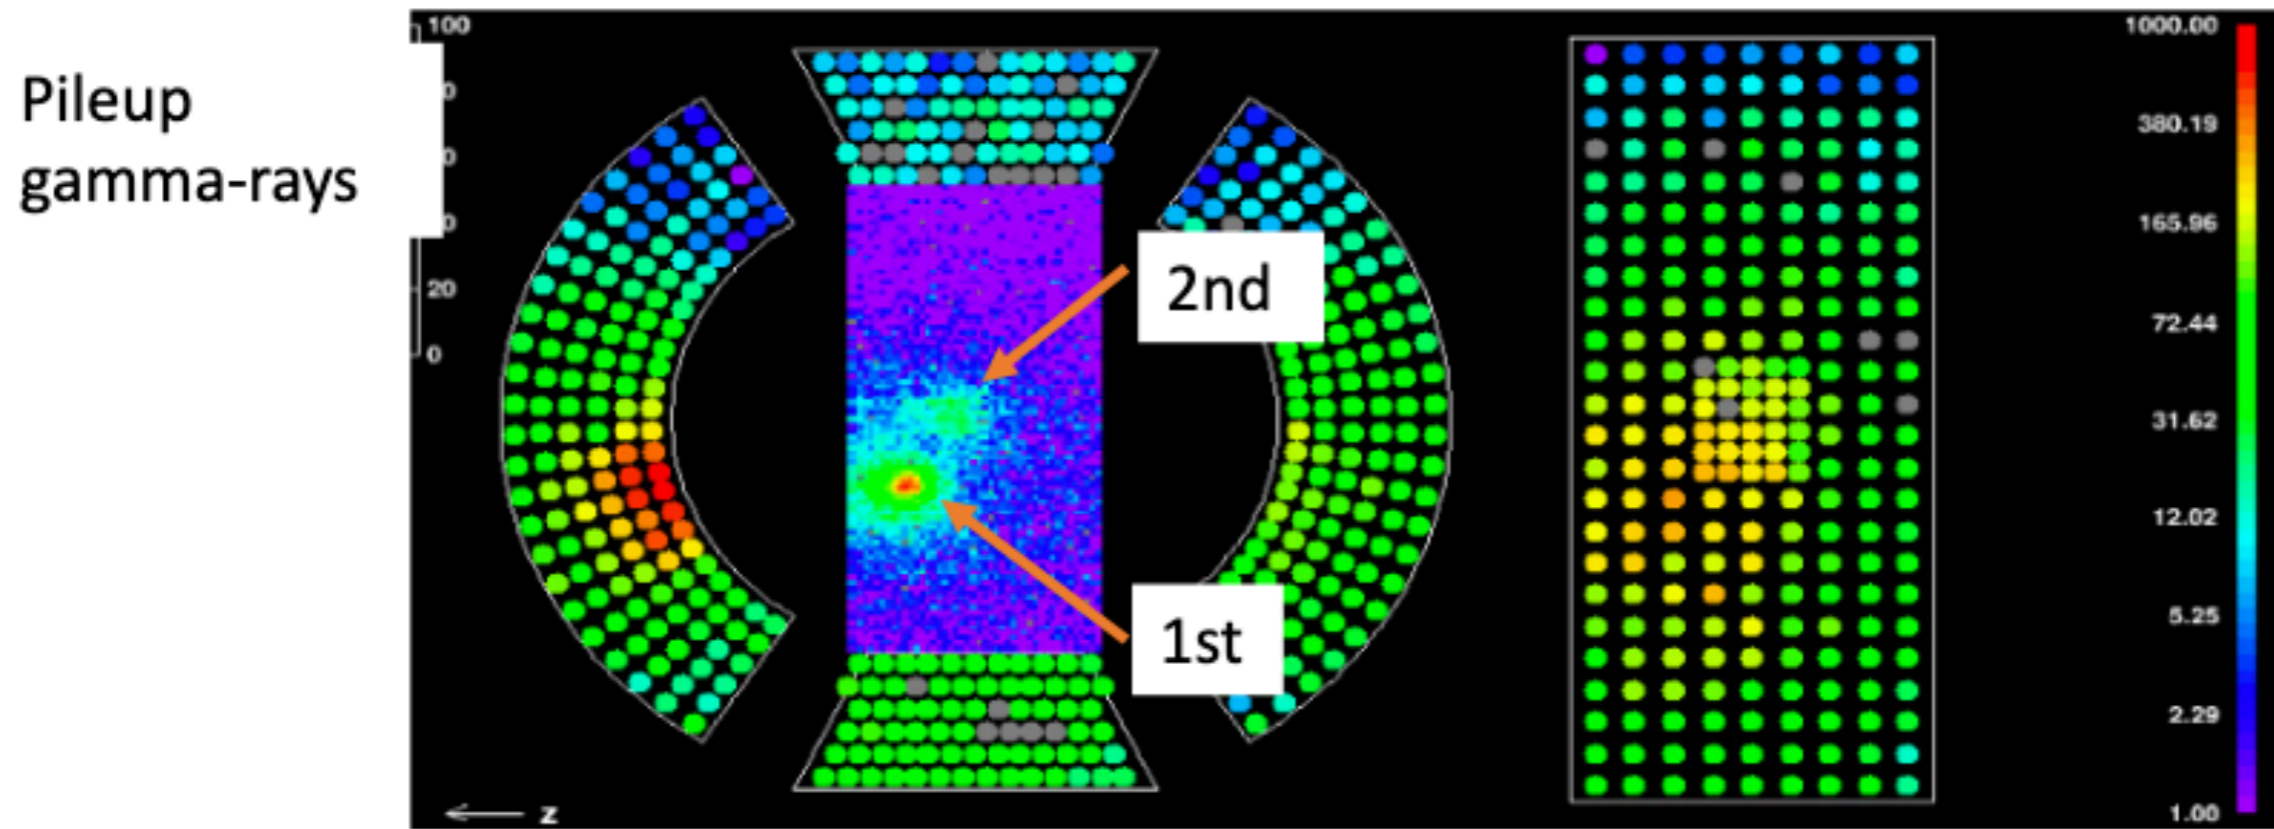

Operation of the liquid xenon detector in 2021 run

- The liquid xenon detector consists of 4092 VUV-sensitive MPPCs on the inner face and 668 VUV-PMTs on the other faces
 - Measuring the energy, position and timing of incoming gamma-rays
- First operation of the full number of readout in 2021
- Noise is reduced by improvement of electronics and analysis

Operation of the liquid xenon detector in 2021 run

- Event display with full number of readout channels

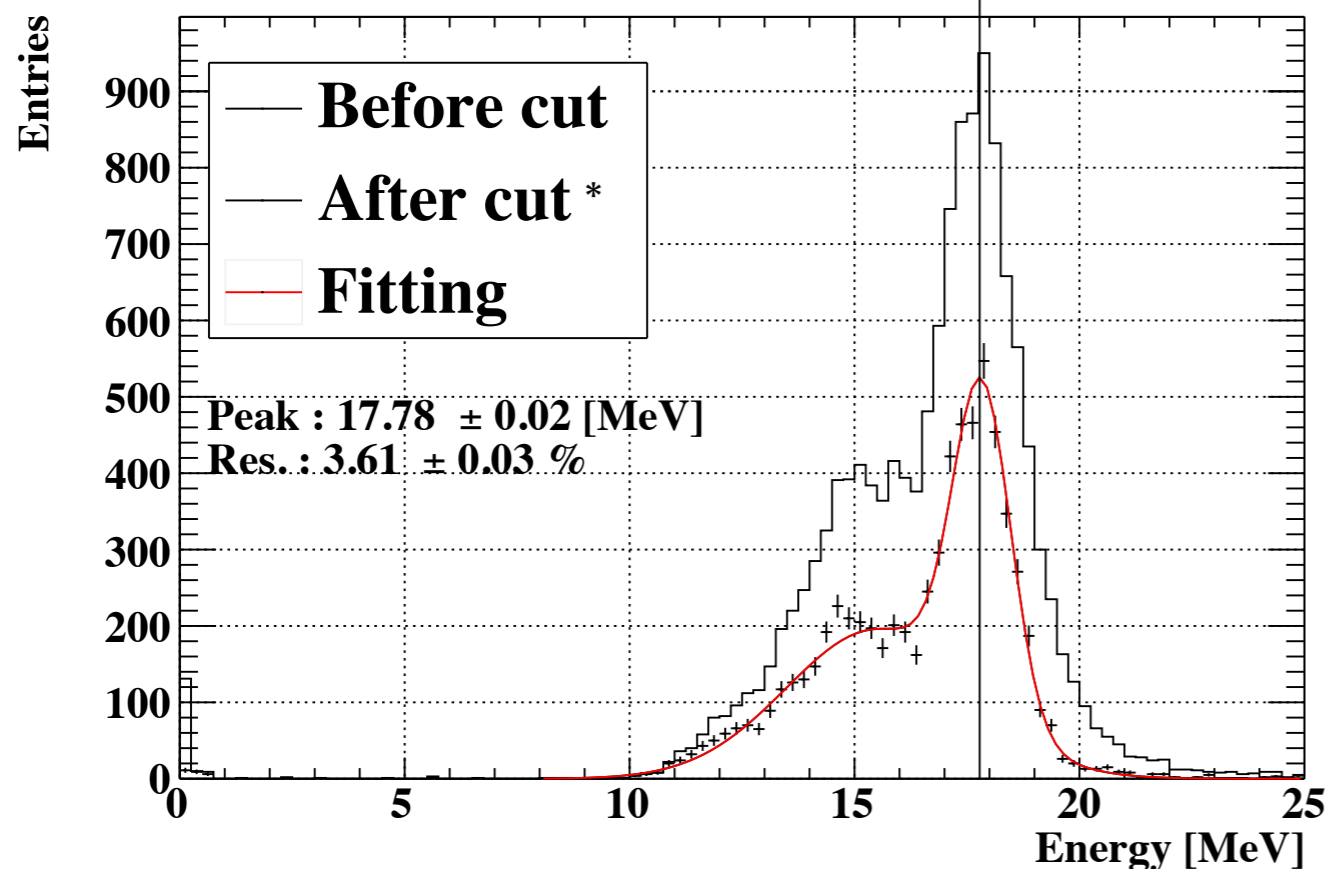

Cosmic-ray
Close to entrance face

Stability of the energy scale

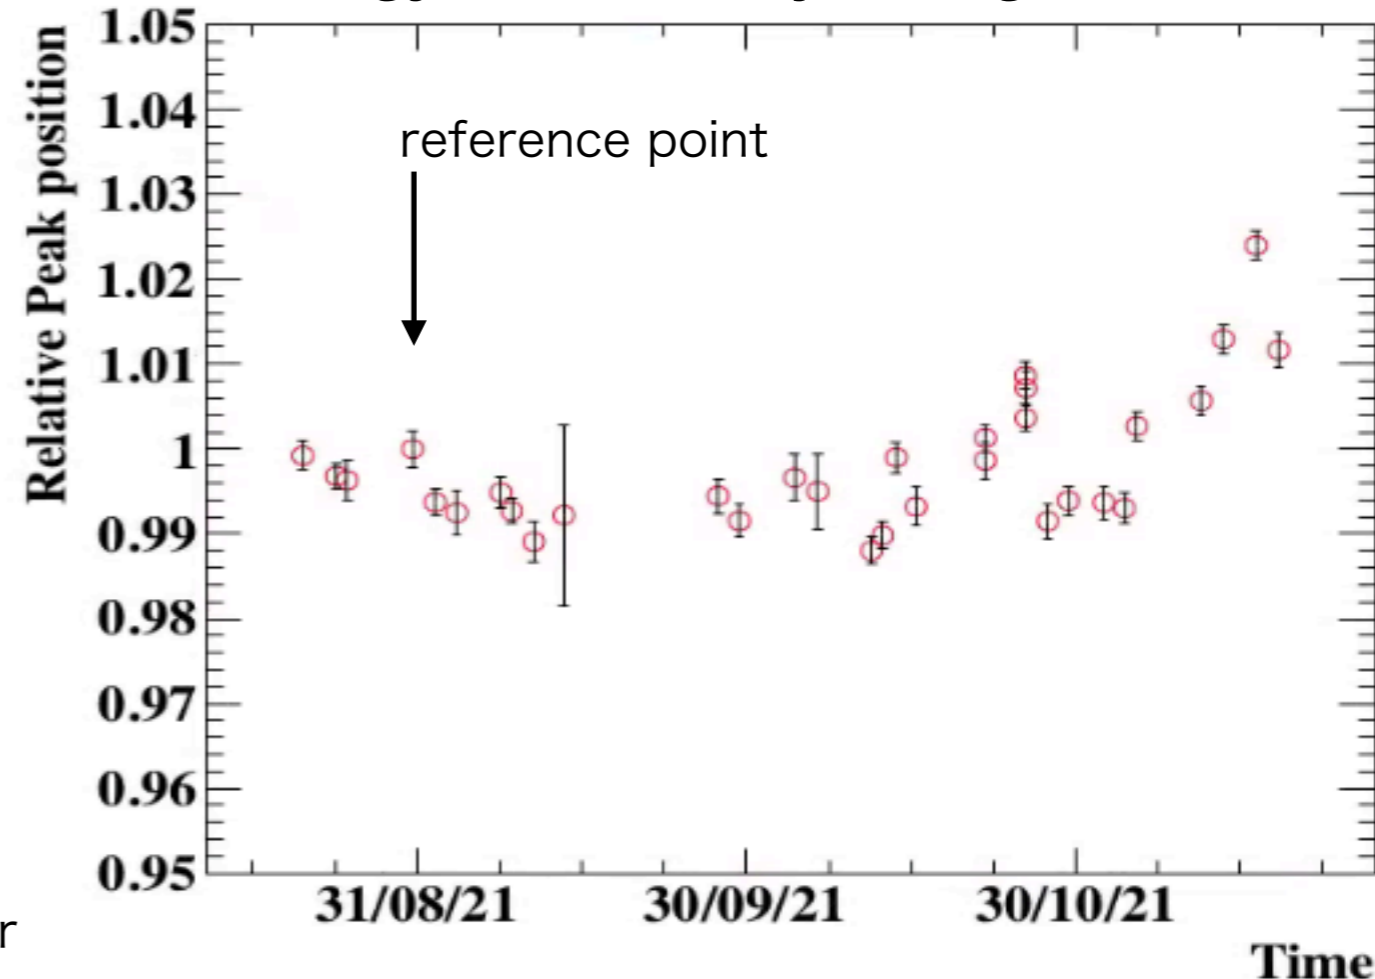

- Performance of the liquid xenon detector was monitored and evaluated using various calibration sources during the beam time
 - LED light, Alpha-ray, Mono-energy Gamma-ray (9 MeV, 17.6 MeV)
- 17.6 MeV gamma-ray from CW accelerator and Li target
 - p (CW acc.) + Li (target) \rightarrow Li(p, γ)Be \rightarrow γ (17.6 MeV)
- For some reason, energy scale increased gradually ($\sim 2\%$)

Example CW-Li energy spectrum

* Event selection : central region of the detector

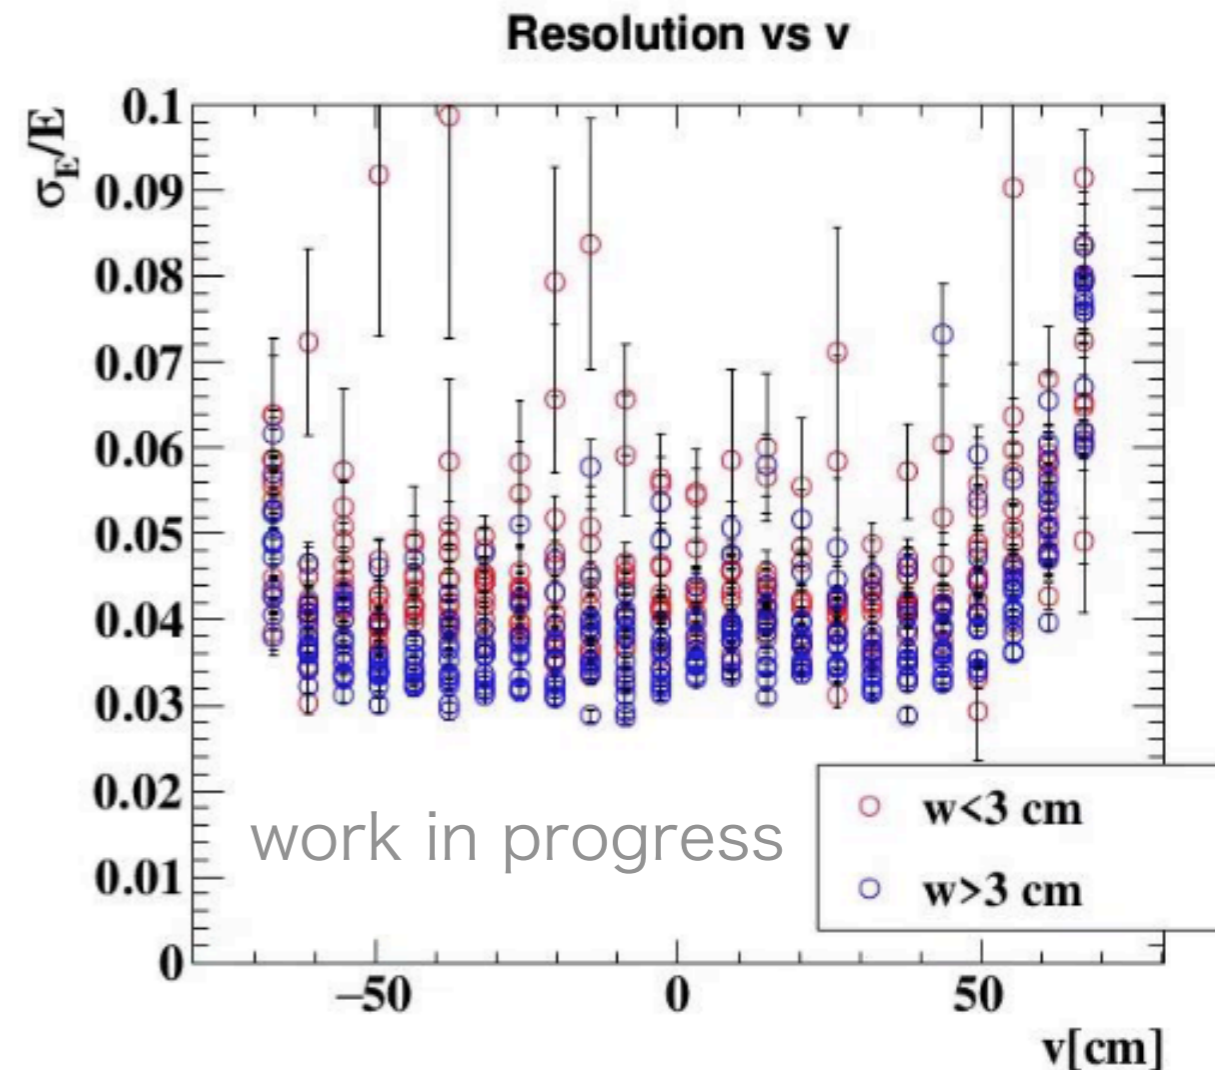

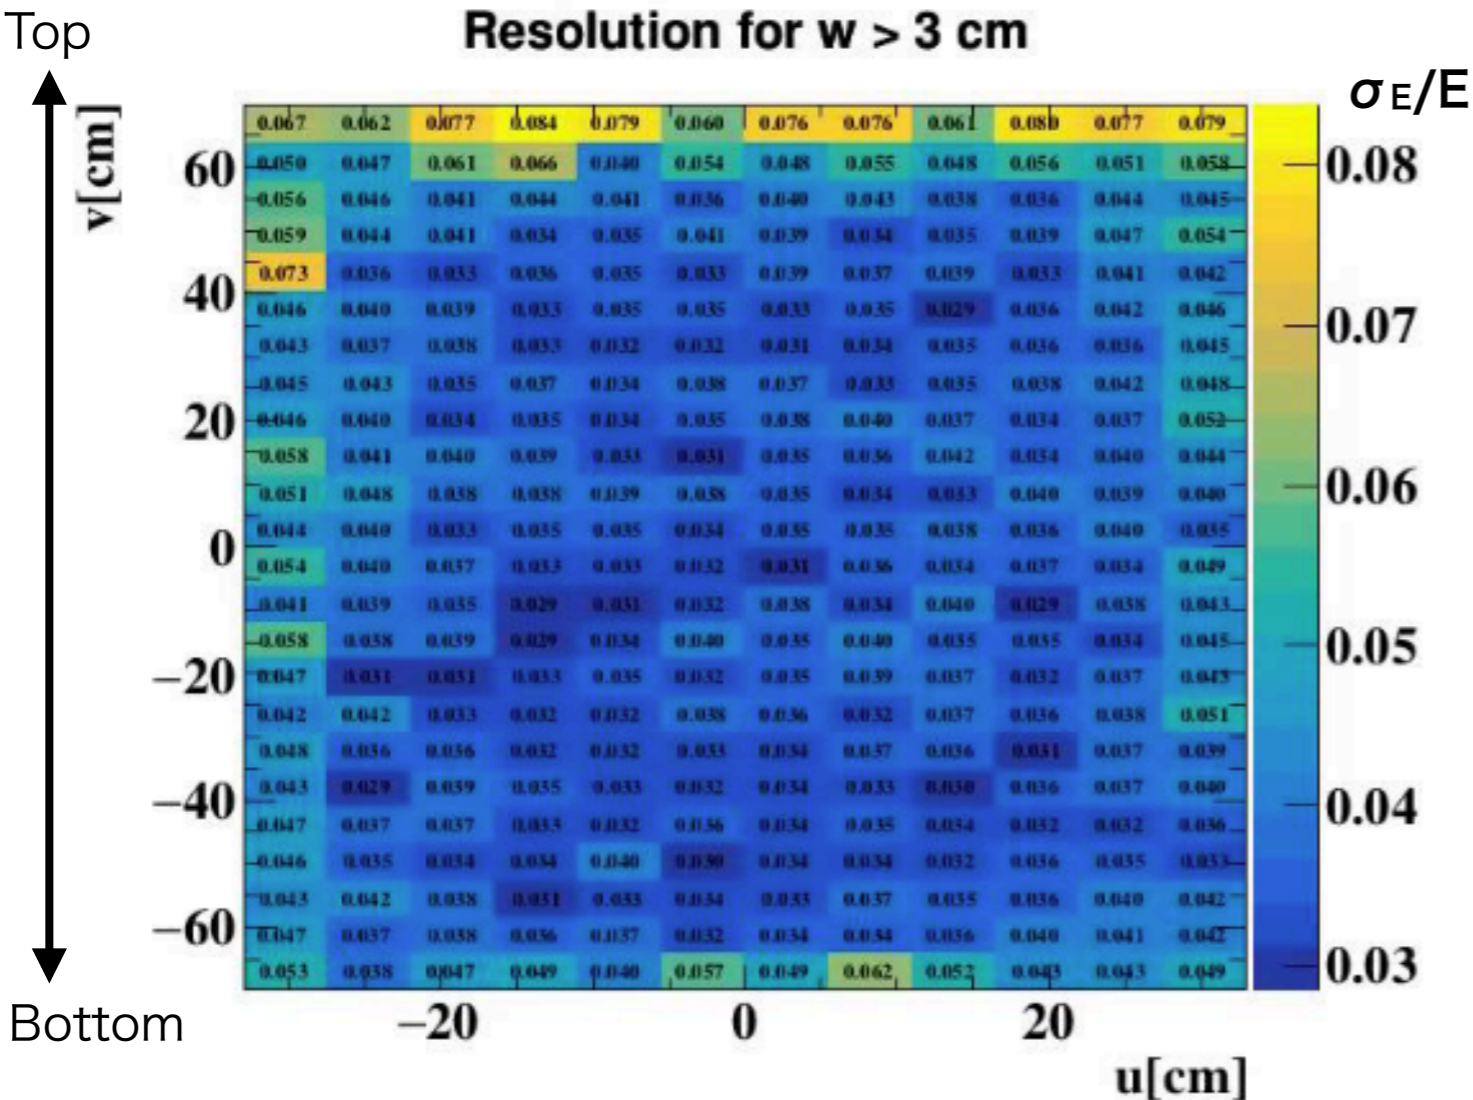

Energy scale history during beam time

Energy resolution

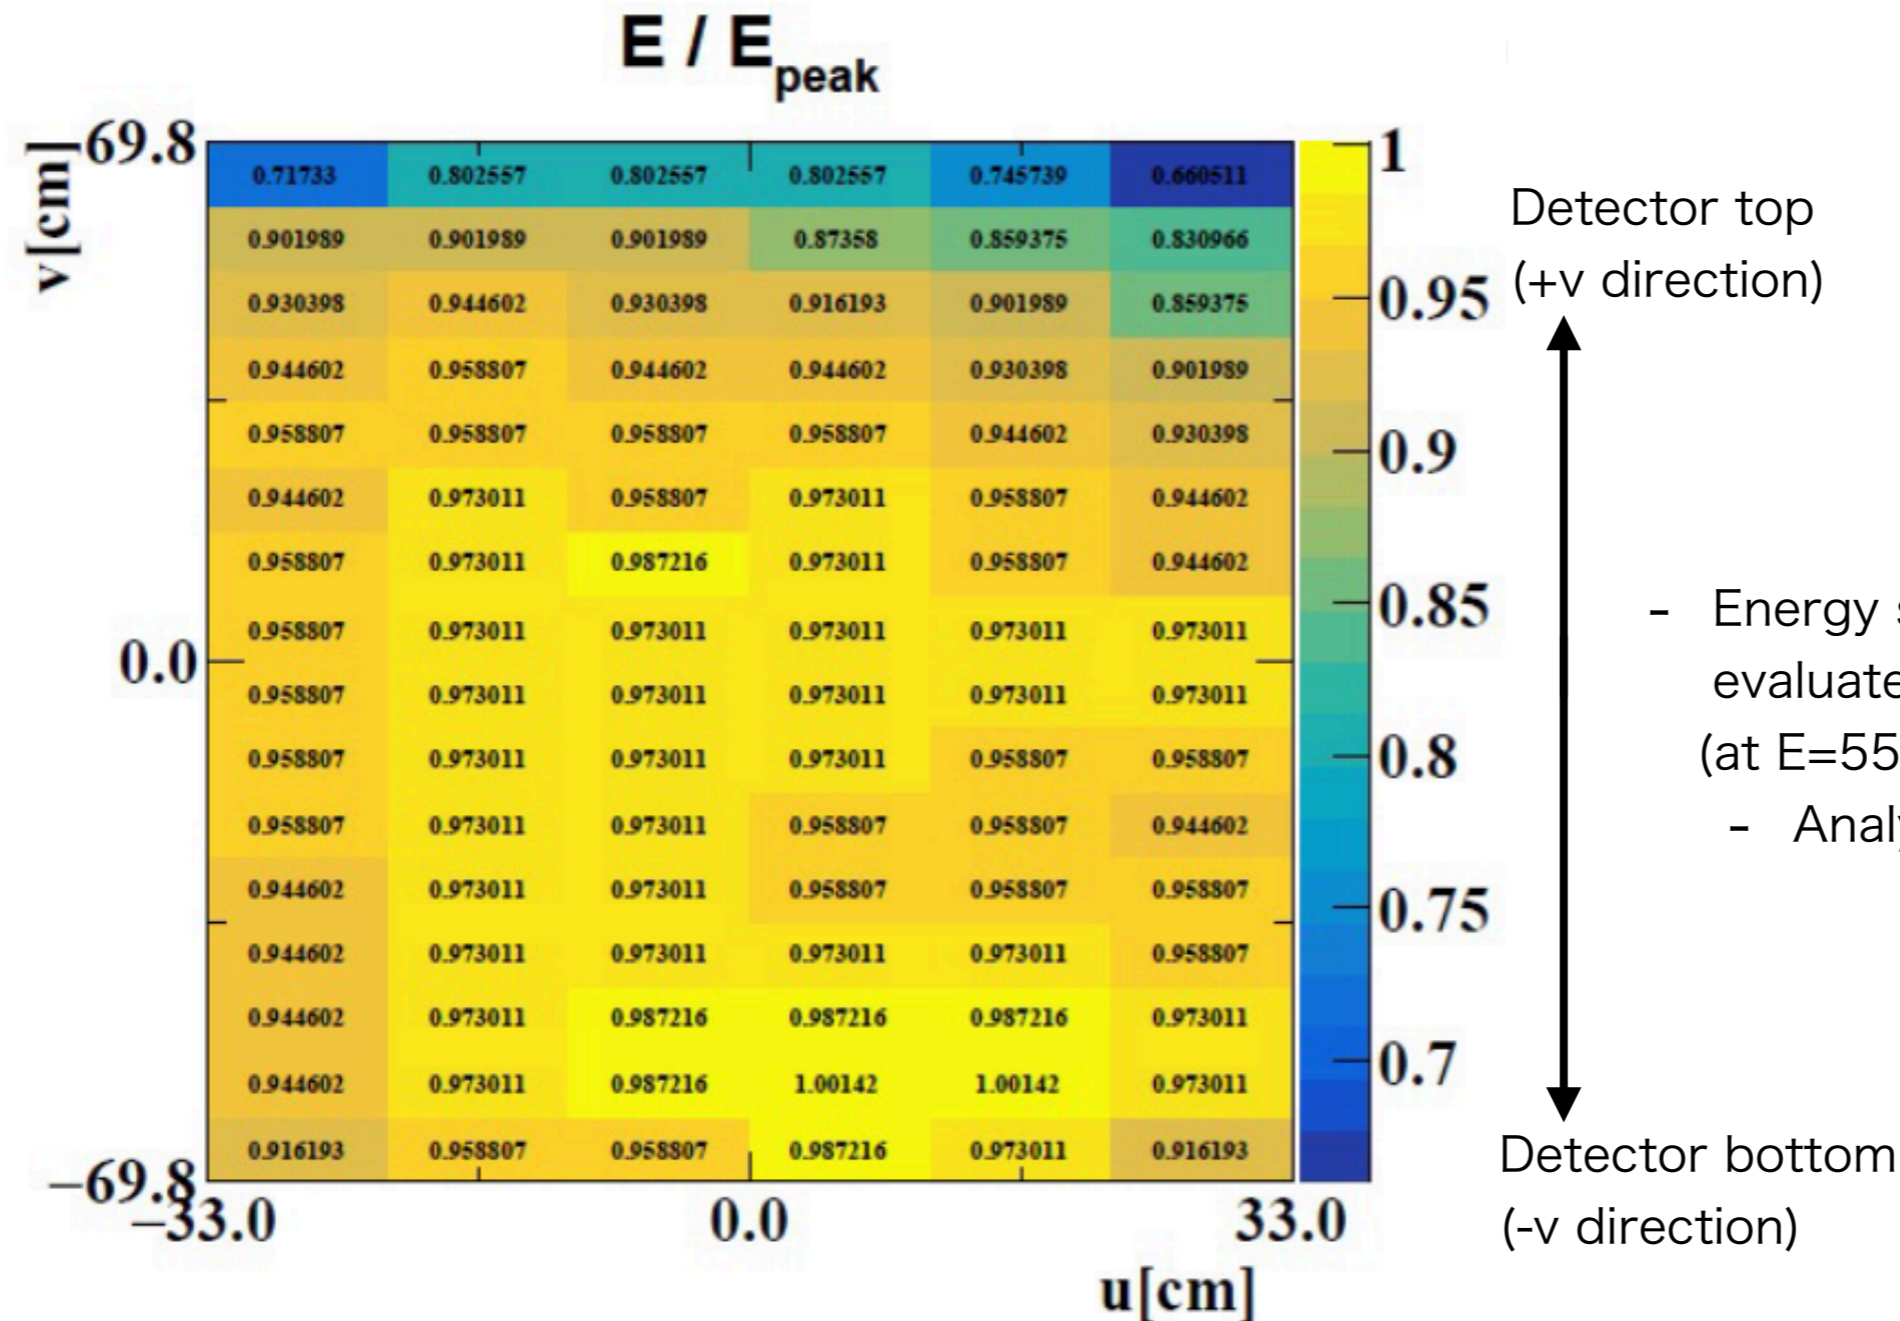

- Energy resolution is also evaluated using 17.6 MeV gamma-ray
- Depth dependence is observed
 - Better E resolution for $w > 3.0$ cm
 - Energy resolution is worse at the top/bottom region
- Almost uniform response is observed except for edges

Definition of the coordinate system

Uniformity of energy scale

- Large non-uniformity, in particular along v-direction again, is observed
 - Larger than the prediction of MC simulation
- Possible reasons :
 - Liquid xenon may not be filled up to the top of detector region
 - Systematic bias of detection efficiency measurement with alpha-sources

- Energy scale and resolution should be evaluated by CEX run in 2021 (at $E=55\text{MeV}$)
 - Analysis is ongoing

Timing resolution

- Timing resolution of the liquid xenon detector was evaluated using back-to-back gamma-rays from pion charge exchange reaction
 - $\pi^- \rightarrow \pi^0$ (in Hydrogen) $\rightarrow \gamma + \gamma$
 - Gamma-ray at the opposite side is detected by Pb+plastic scintillators and BGO crystals

- Absolute timing resolution is calculated as follow:

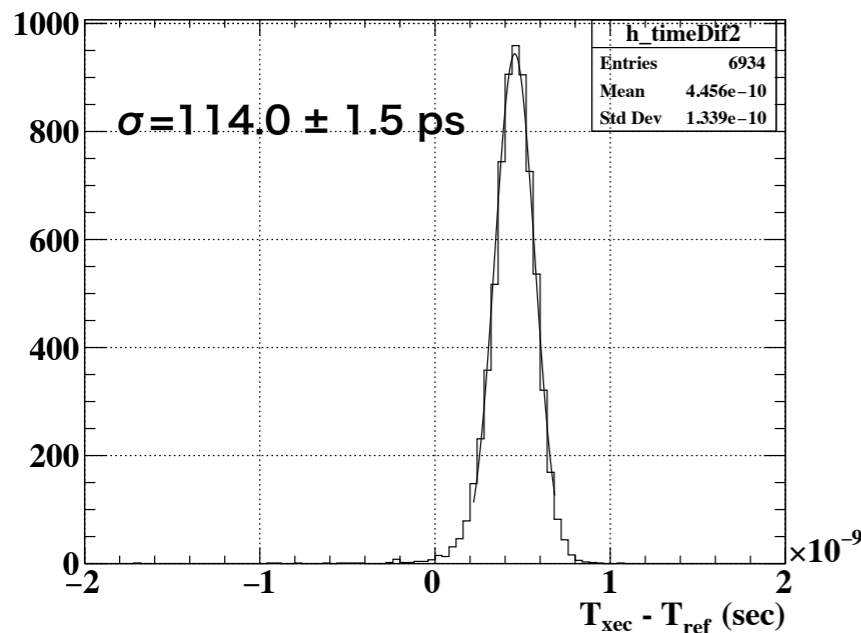

$$\sigma_{\text{abs}} = \sigma(T_{\text{XEC}} - T_{\text{ps}} - T_{\text{TOF}}) \ominus \sigma_{\text{ps}} \ominus \sigma_{\text{vertex}}$$

70.0ps

→corresponding to 10.5mm vertex size

xec-ps time dif (TOF correction, 55MeV)

plate time dif

Position dependence of timing resolution [ps]

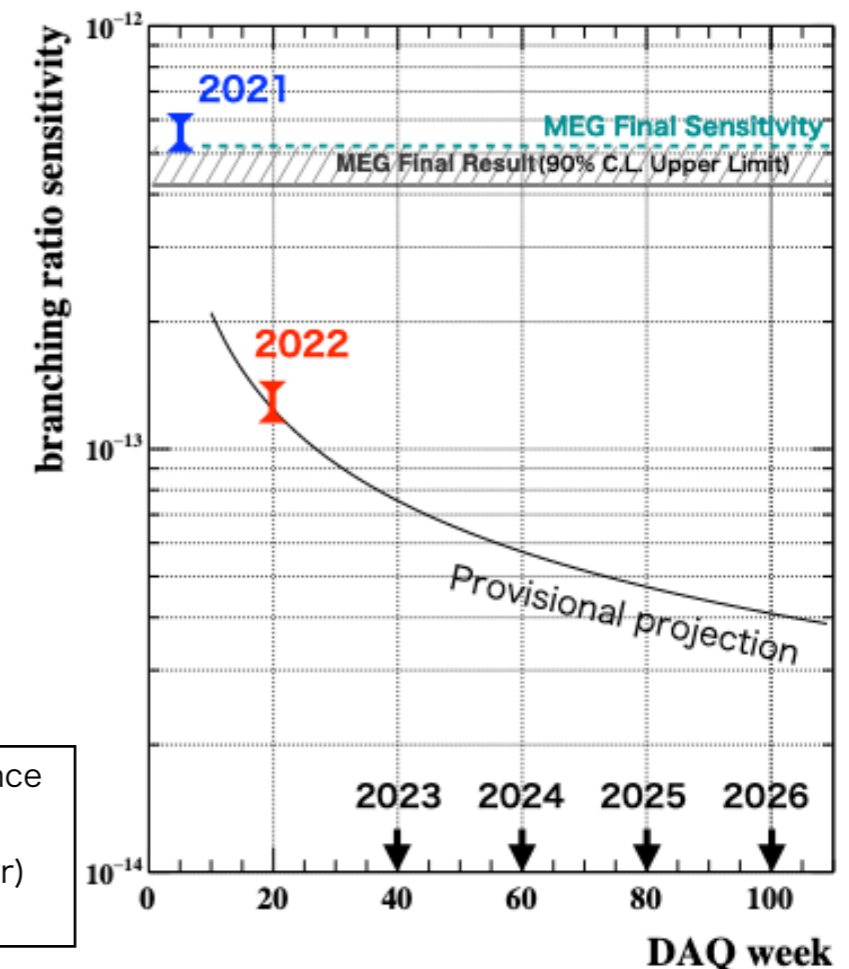

- Absolute timing resolution of the liquid xenon detector : **85.4±5.1 ps**

Detector performance and sensitivity

- Summary of the detector performance (including positron side)
 - These values will be improved more by detailed analysis

	ΔE_γ	ΔX_γ	ϵ_γ	ΔP_e	$\Delta\theta_e$	ϵ_e	$\Delta T_{e\gamma}$
MEG	1.7% <small>w>2cm</small>	5mm	63%	380keV/c	9.4mrad	30%	122ps
MEG II goal	1.7% <small>w>2cm</small>	2.4mm	69%	100keV/c	6.7mrad	65%	70ps
MEG II achieved	1.8% <small>w>2cm measured in 2020</small>	2.4mm <small>measured in 2018</small>	69% <small>by simulation</small>	<150keV/c	7.2mrad	>47%	<100ps

- Expected sensitivities
 - Data 2021 : $(5.3 - 6.1) \times 10^{-13}$
 - Already approaching MEG sensitivity (5.3×10^{-13})
- Prospect of the sensitivity,
 - Data 2021+2022 : $(1.3 - 1.4) \times 10^{-13}$
 - Well beyond MEG

- Provisional projection curve based on expected detector performance ("MEG II goal" in the summary table)
- Assume 20 DAQ weeks per year, (6 month beam time for every year)
- DAQ time 2021 with correction for fraction of physics run

Run in 2021

Liquid Xenon Detector in 2021 run

Run for 2022 : Annealing of MPPCs

Summary

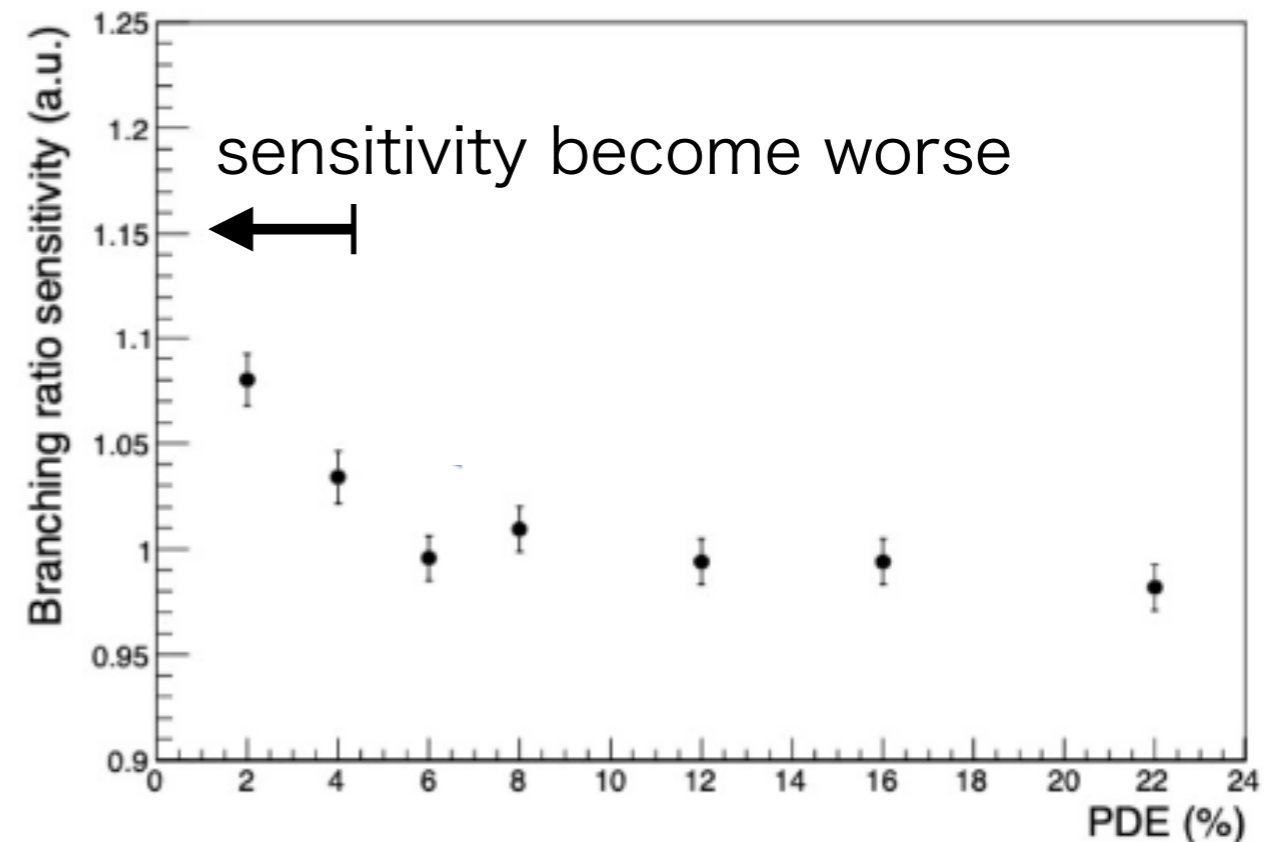

Liquid xenon detector / PDE decrease

- Photon Detection Efficiency (PDE) decrease was observed in 2021 run
 - known problem since 2017
 - Averaged PDE : 8.4% \rightarrow 5.6%
 - The cause of PDE decrease is under investigate (radiation damages?)
- PDE < 2-4%, reachable in 2022, will worsen the sensitivity
 - Recovery of PDE is essential task to make the experiment sustainably
- By previous works, we know **“annealing” (heating) process recovers PDE**
 - PDE of 11% is required to stand $4e+7$ μ/s beam in 2022 (14% for $5e+7$)

MPPC PDE vs Irradiation time

by simulation work

Annealing with hot water circulation

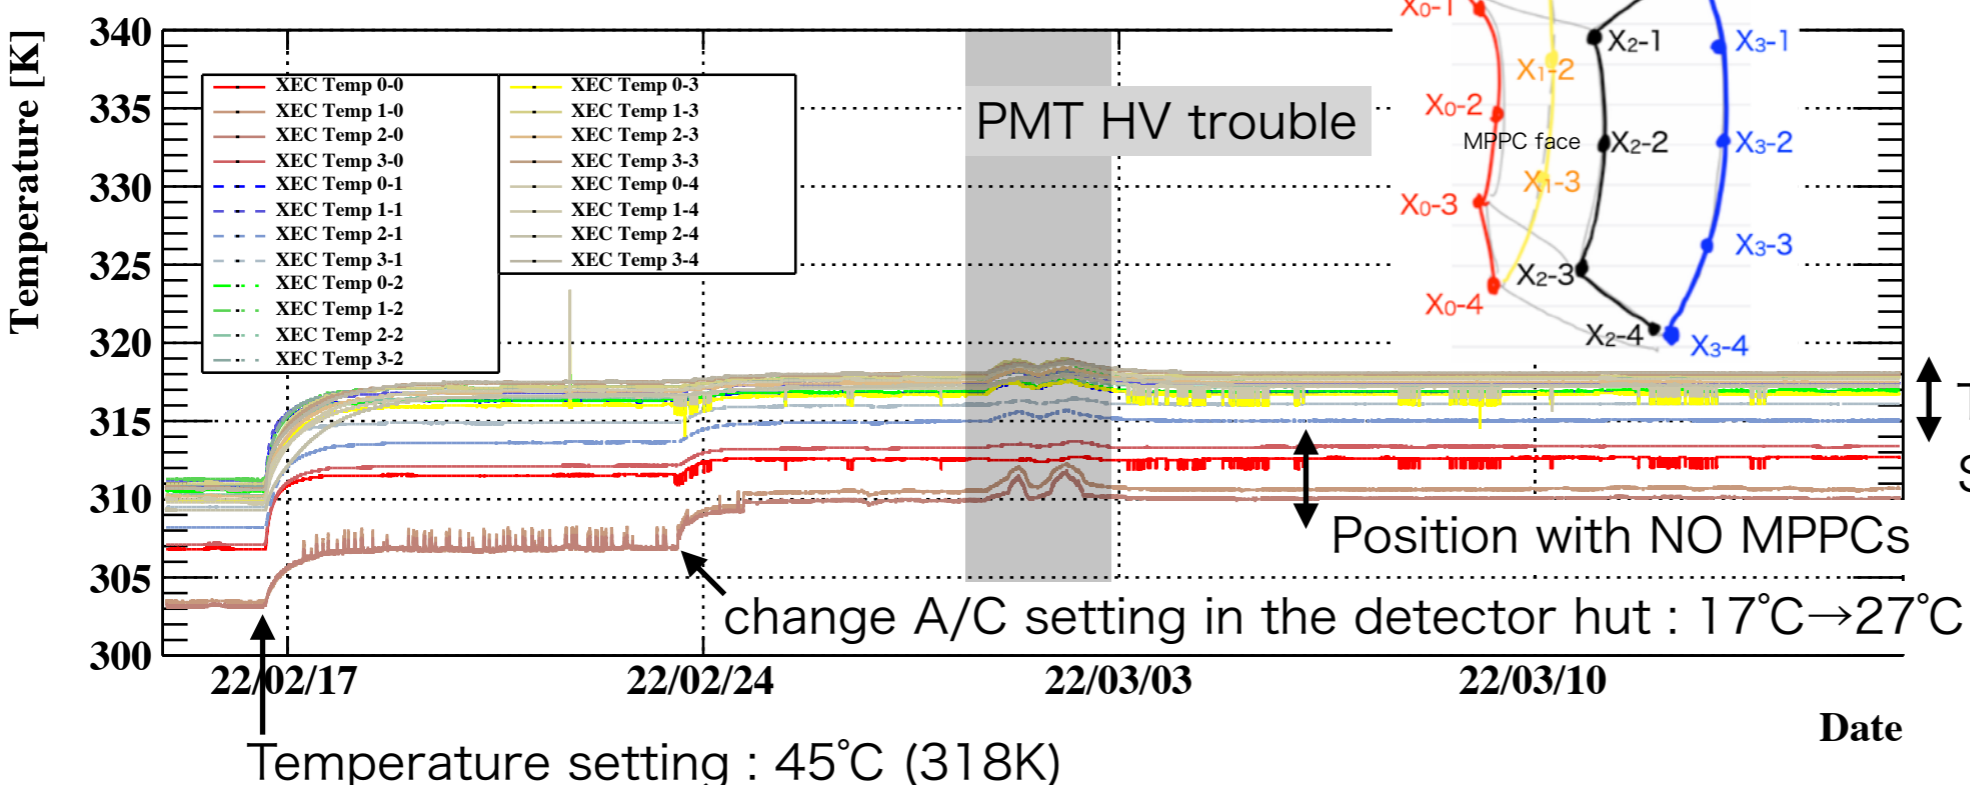

- Circulating hot water through the cooling pile that surrounds the detector
- Be able to heat up entire of the detector easily
- The temperature of hot water is limited up to 45°C because of the limitation from detector components
- Annealing with hot water was conducted for one month
- Recovery of PDE is monitored and estimated with visible LED light
 - Strong correlation with PDE for VUV light

Heating (circulator) pump

LXe detector

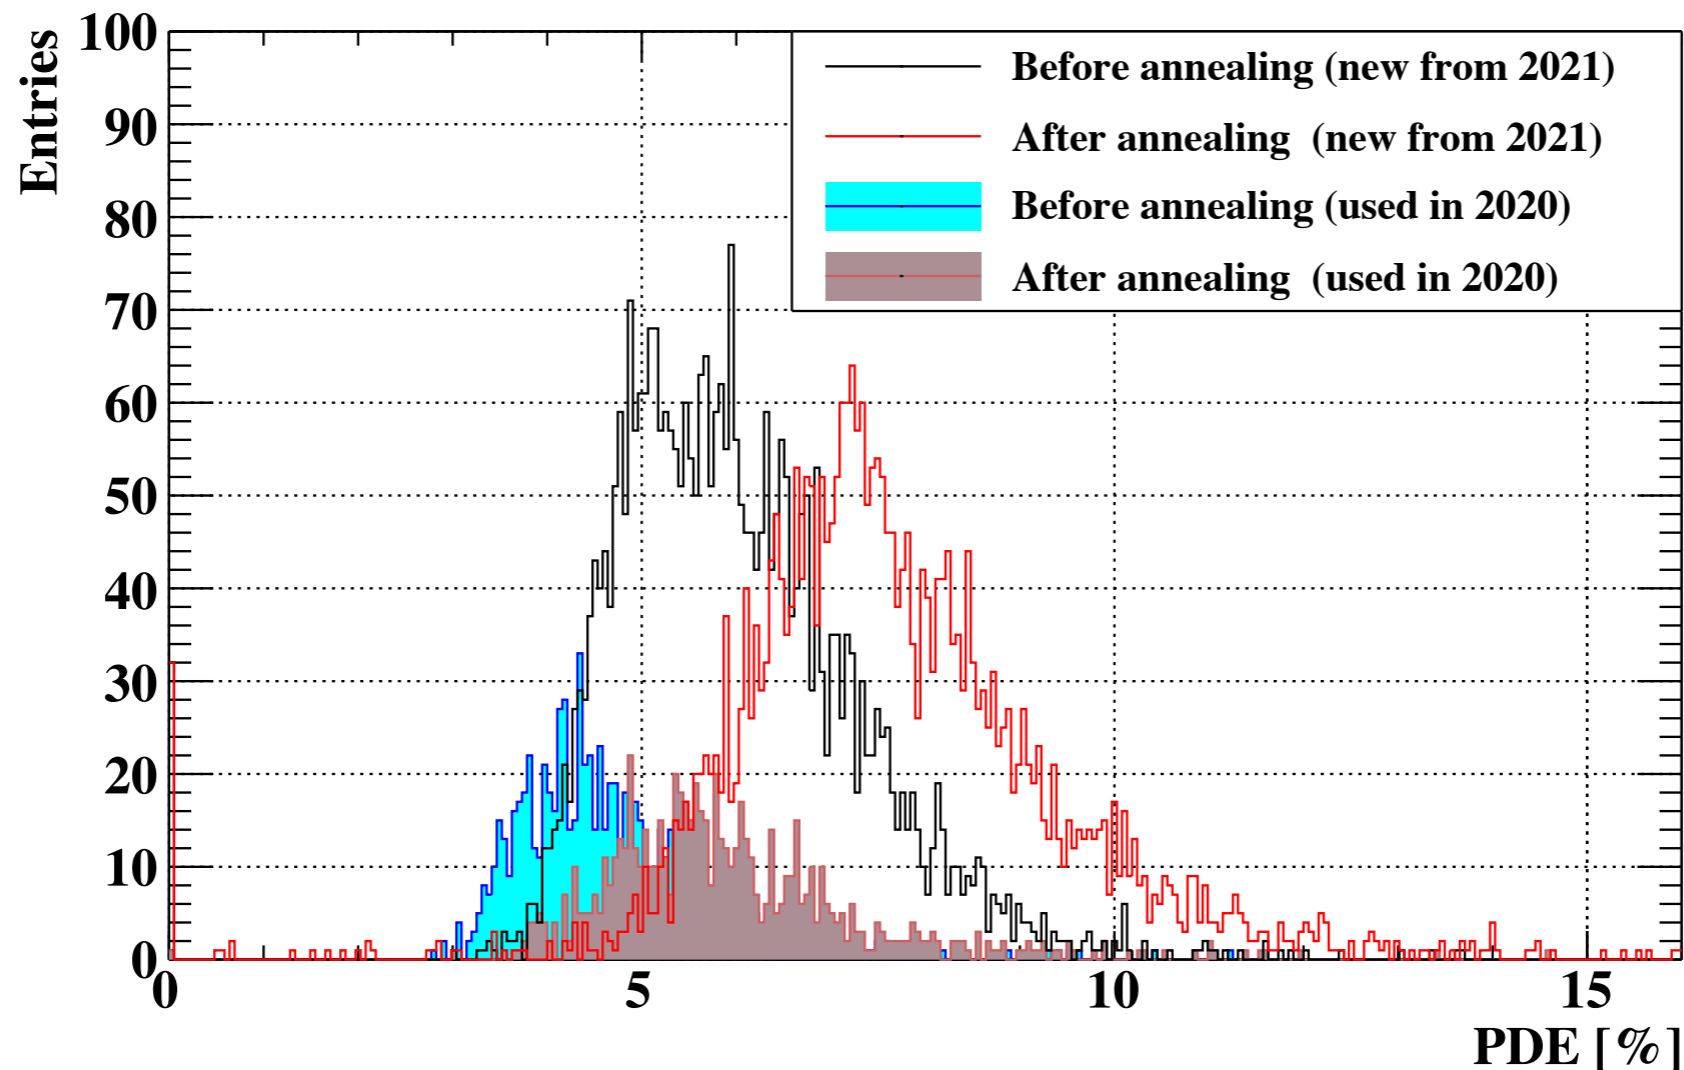

Temperature is monitored by sensors inside the detector

Temp. are within 3°C range
Stable within 0.1°C

Annealing with hot water circulation

- Absolute PDE value (for VUV) before/after the hot water annealing
 - Average PDE value of MPPCs used before 2020 : 4.56% \rightarrow 5.98% (x1.31)
 - Average PDE value of MPPCs used since 2021 : 6.02% \rightarrow 7.79% (x1.29)
- Slower than the expected recovery speed : 30 %/month $<$ \sim 145 %/month_(expected)
- Note that the PDE value is not fixed
 - “Before” value contains large uncertainty : still continuing to improve analysis
 - “After” PDE value is estimated value using visible LED

Annealing by Joule heating

- MPPC is annealed by Joule heating using a high current source and LED light
 - Heated with $\sim 1.7W$ per MPPC
- MPPCs with an interval of 4 are annealed at once
 - Avoid over heating of the detector
 - 240 MPPCs are annealed at once
 - \rightarrow 17 set of annealing is required (30h/set)

Power supply with large current : 250 mA/output, 60~80 V

Annealing by Joule heating

- Current status of Joule heating annealing
 - ~3300 MPPCs have been annealed
 - the remaining MPPCs will be annealed within this week (~ 28th May. 2022)
- **We are (almost) ready for the beam time this year : PDE more than 11%**
 - The method for PDE recovery by Joule heating annealing is established
 - annealing will be conducted every year (after beam time)

- Note that the PDE value is not final value (contains large uncertainty)
 - “Before” value contains large uncertainty : still continuing to improve analysis
 - “After” PDE value is estimated value using visible LED, not be measured by VUV light

Black : PDE before annealing
Blue : PDE after annealing

Run for 2022 : Annealing of MPPCs

Summary

Back up

PDE decrease

Slide from T. Iwamoto (JPS Mar. 2021, talk: 15aA562-4)

γ detector (LXe) Issue

- MPPC PDE decrease
 - observed in 2017 under muon beam
 - The cause to be investigated
 - Based on 2021 operation, PDE will change from 16% to 2% in ~ 100 days MEG II intensity
 - Annealing recovers PDE fully
- Strategy for run 2022
 - LXe MPPC can sustain ~ 120 days with $5 \times 10^7 \mu/s$
 - Beam intensity optimization necessary
 - **Annealing for all MPPCs** during accelerator winter shutdown period

Goal of annealing this year

- Goal of Annealing this year
 - Recovered amount of charge (PDE) for LED can be translated into that for VUV
 - $\Delta R_{\text{PDE for VUV}} = 10 \times \Delta R_{\text{PDE for LED}}$
 - relatively 10% recovery for LED light corresponds to relatively 100% recovery VUV-light
 - Required PDE value is (absolute) 14% for 120 days beam time with $5e+7$ intensity
 - In average, (absolute) ~5.5% at the end of 2021 run (before annealing)
 - \rightarrow Relatively 15% charge recovery for LED is required
 - In principle, absolute PDE value will recover to 20% (initial value at manufactured)

Estimation of charge recovery by hot water annealing

- Estimation based on 2019 Joule annealing
 - The neighboring channels of annealed MPPC were also warmed to $\sim 40^\circ\text{C}$
 - Because of heat conductivity through PCB, measured in Lab. test

Monitored charge using LED (adjacent MPPCs) as a function of integrated annealing time

- It will take 500 h = **20.8 days** to recover (relatively) 10% charge for LED light
- 1000 h = **41.6 days** are required to recover (relatively) 20% charge for LED light

- NOTE that this estimate is just obtained just extrapolating the previous trial

→ **There is no guarantee that the PDE recovers to the target value at $\sim 45^\circ\text{C}$**

→ one of what we have to study by this year's trial

Temperature limitation

CFRP should not exceed 45°C

→ the maximum temperature setting in hot water annealing must be 45°C

- Temperature limit
 - MPPC: 100°C
 - PCB: 120°C
 - CFRP: 45°C
 - Glue: 65°C

Annealing with hot water circulation

- Circulating hot water through the cooling pile that surrounds the detector
- Be able to heat up entire of the detector easily
- The temperature of hot water is limited up to 45°C because of the temp. limitation of detector components

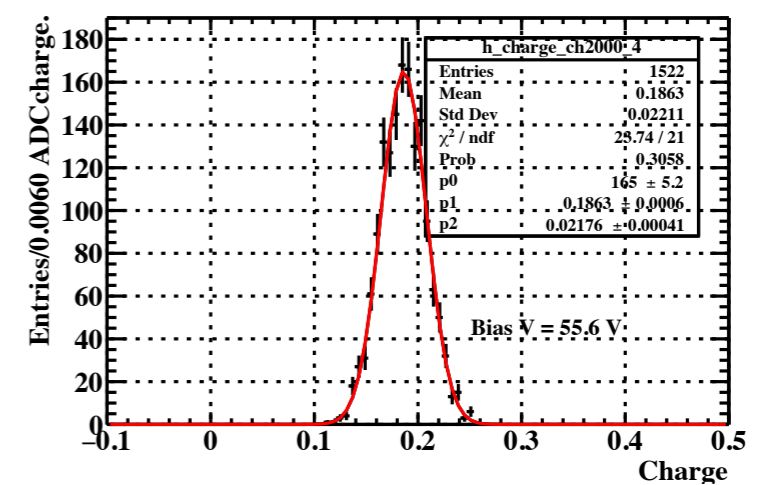

(by previous work)

- PDE recovery can be estimated from the PDE for blue LED (installed in the detector)
- Correlation exists between PDE_{VUV} and PDE_{LED} : $PDE_{LED} \sim 0.1 \times PDE_{VUV}$
- The expected value of charge increase is 1~5% for one month annealing at 45°C

Annealing with hot water circulation / MPPC charge

- LED data with various bias voltages are taken for monitoring the PDE_{LED}
- Breakdown voltages are estimated by extrapolating the gain curve with linear fit
- Example charge distributions and gain curve of an MPPC at the central region

Annealing with hot water circulation / MPPC charge

Charge at constant bias voltage
(sum of 55.6, 56.0, 56.4, 56.8 V)
- sum charge of ~400 MPPCs
- NOT normalized by PMT charge

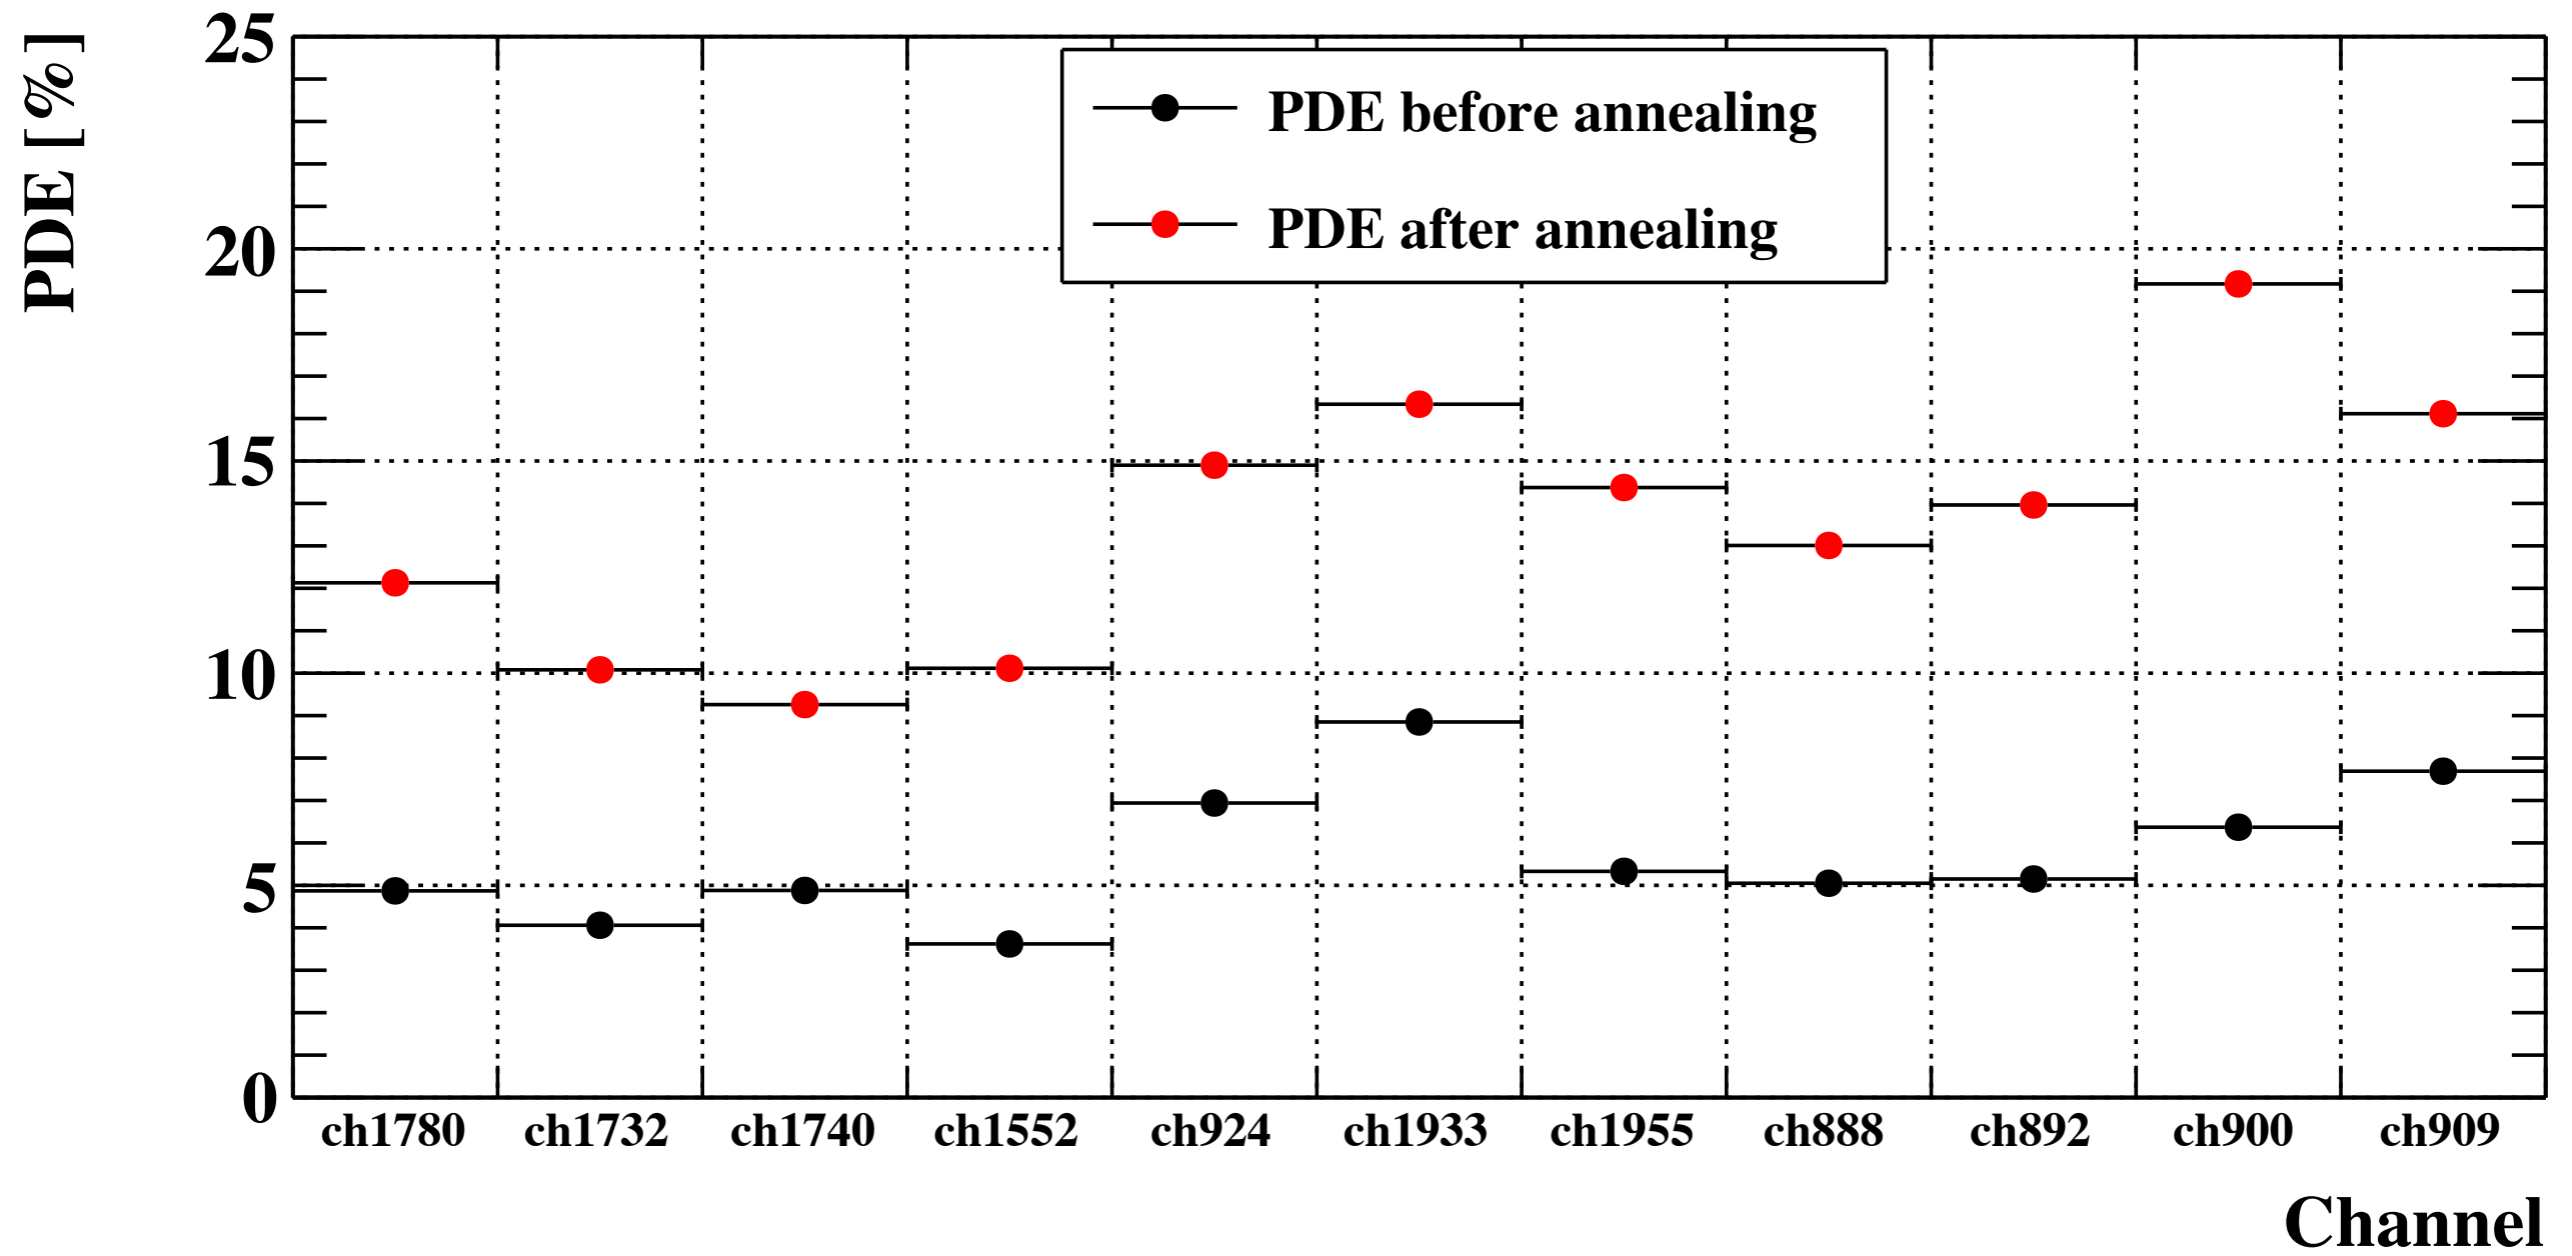

Slight charge increase can be seen
- ~1.2% after the temperature
becomes constant

- Should be monitored carefully more

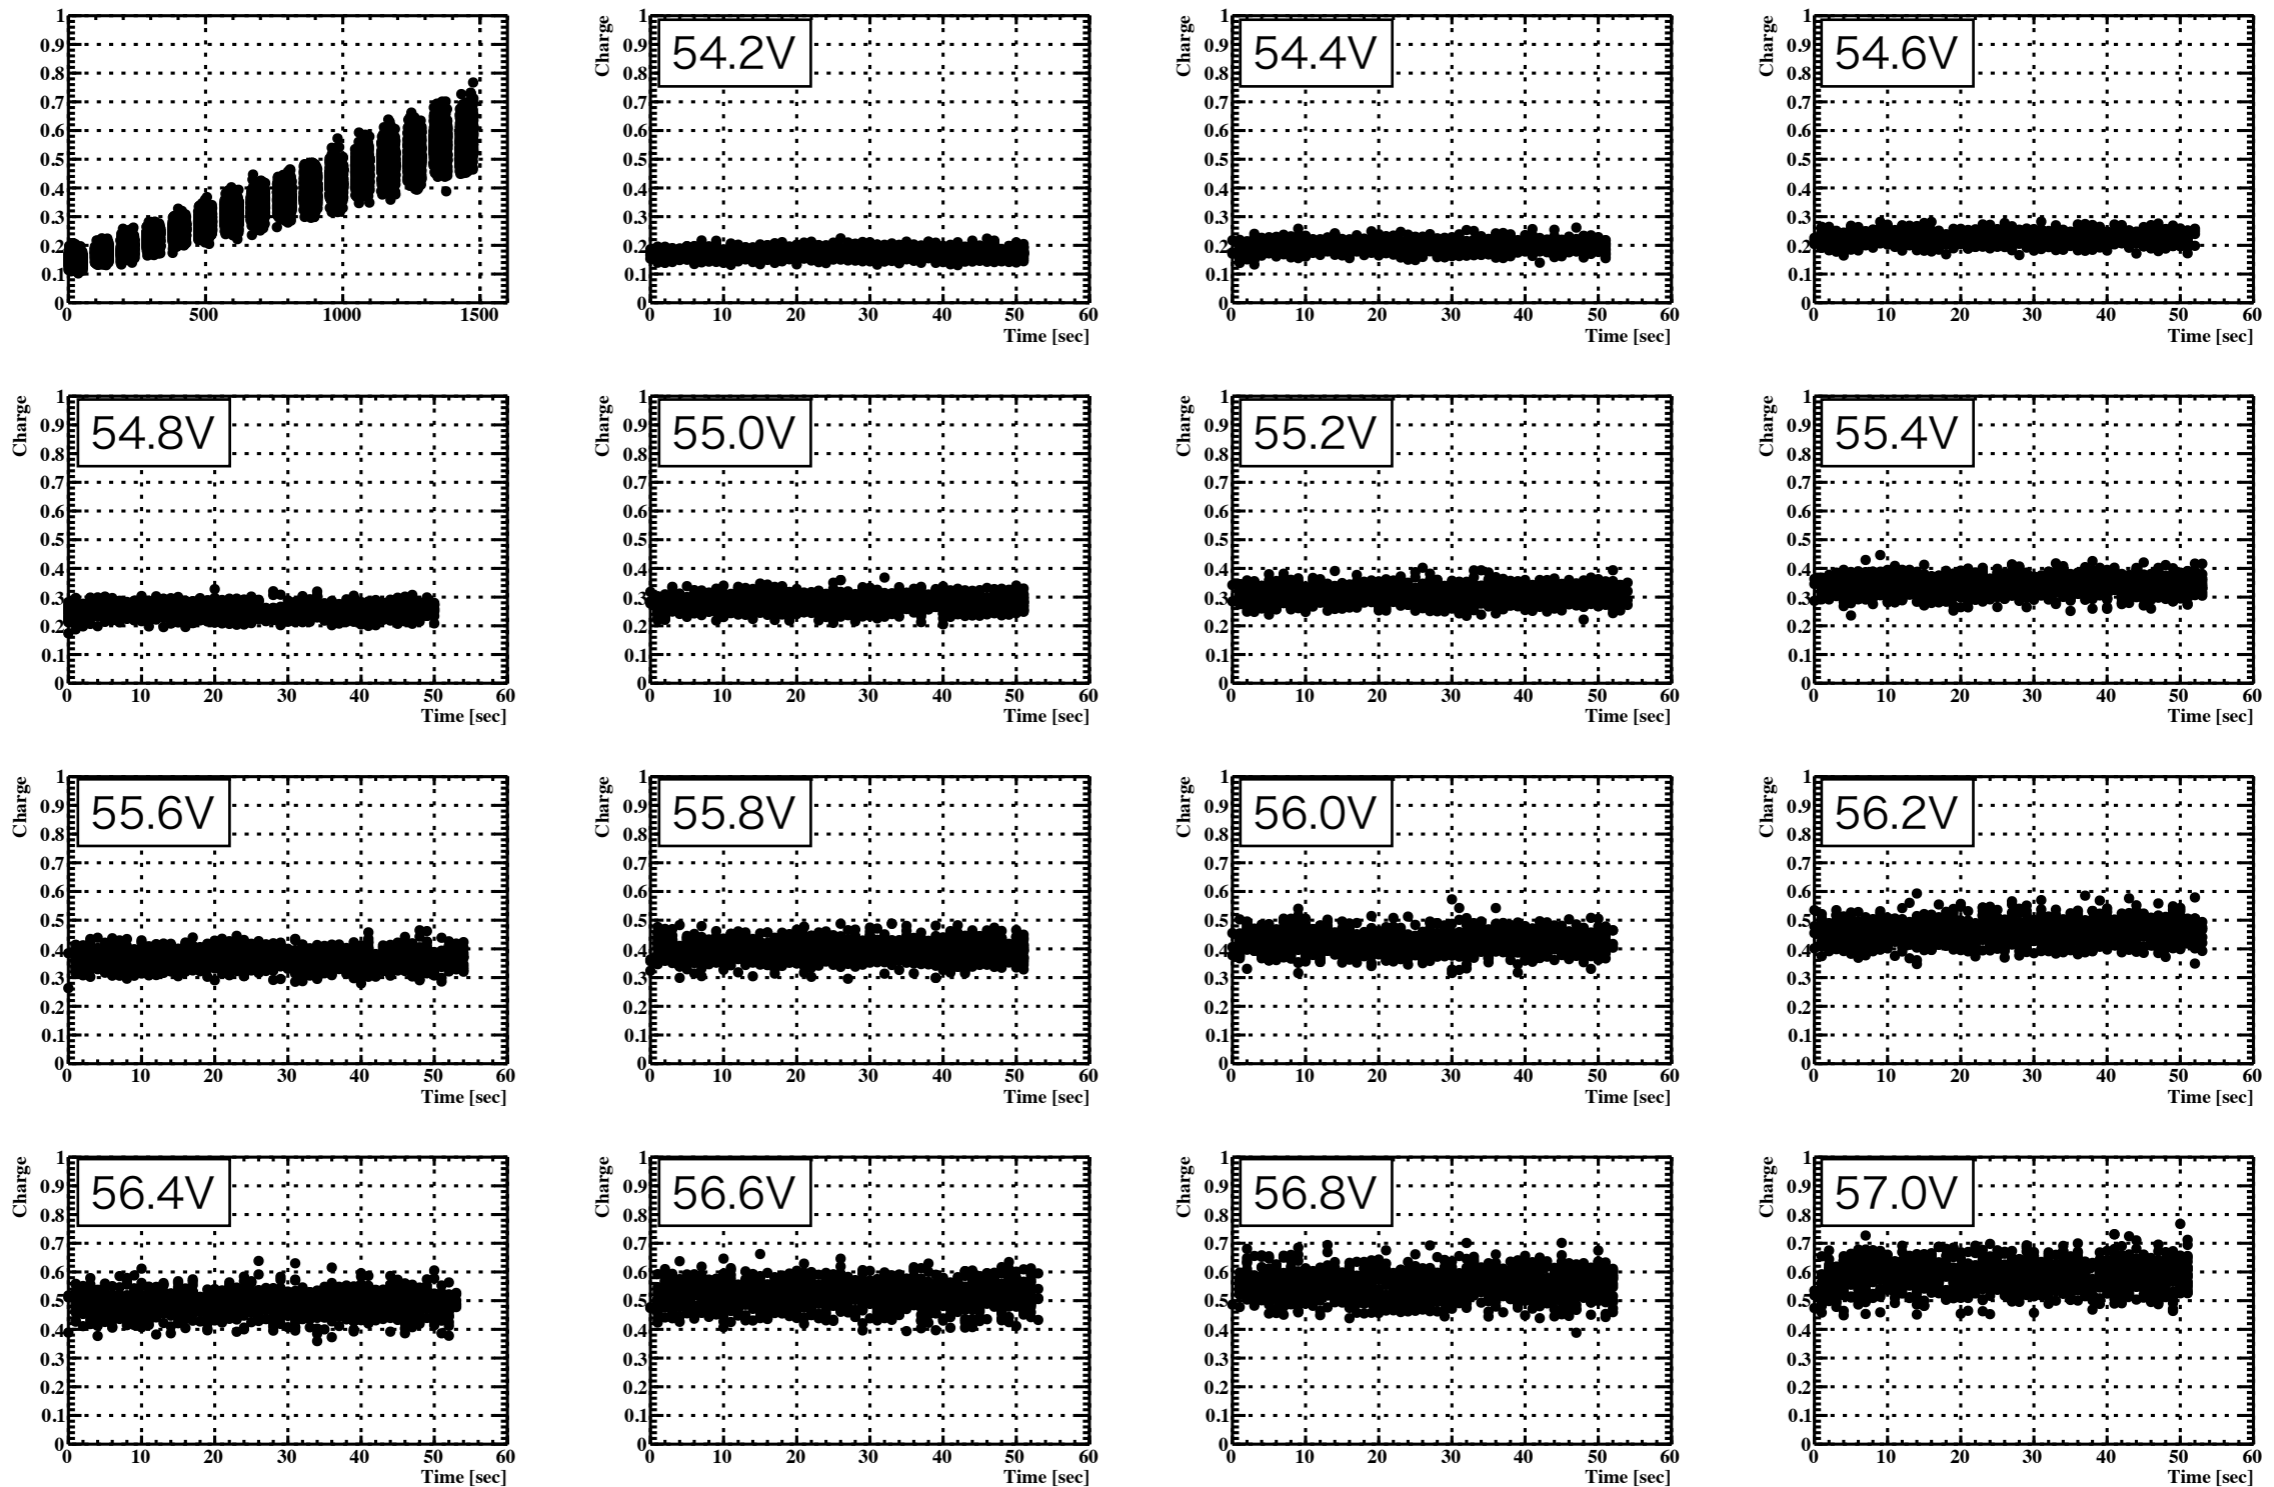

Summary of Joule annealing (small num. test)

- Summary of small number test
- PDE after annealing is estimated by charge ratio both of the hot water annealing and Joule annealing

Charge vs time : effect of temperature decrease

- Charge vs time
 - Dataset : run421165 - 421181 (after annealing of ch4), ch1000
 - No time dependence is observed

Calculate breakdown voltage and charge

- Charge vs time

- Dataset : run421165 - 421181 (after annealing of ch4), ch1000

- Example of how to calculate $V_{breakdown}$ and its result

- Charge at over voltage : 3.0 V is used to evaluate the annealing effect
