Something Funny Happened on the Way to the 21st Century

ν Flavor Oscillations

Neutrino oscillation experiments have revealed that neutrinos change flavor after propagating a finite distance. The rate of change depends on the neutrino energy E_{ν} and the baseline L. The evidence is overwhelming.

- $\nu_{\mu} \rightarrow \nu_{\tau}$ and $\bar{\nu}_{\mu} \rightarrow \bar{\nu}_{\tau}$ atmospheric and accelerator experiments;
- $\nu_e \to \nu_{\mu,\tau}$ solar experiments;
- $\bar{\nu}_e \to \bar{\nu}_{\text{other}}$ reactor experiments;
- $\nu_{\mu} \rightarrow \nu_{\text{other}}$ and $\bar{\nu}_{\mu} \rightarrow \bar{\nu}_{\text{other}}$ atmospheric and accelerator expts;
- $\nu_{\mu} \rightarrow \nu_{e}$ accelerator experiments.

The simplest and **only satisfactory** explanation of **all** this data is that neutrinos have distinct masses, and mix.

What is the New Standard Model? $[\nu SM]$

The short answer is – WE DON'T KNOW. Not enough available info!

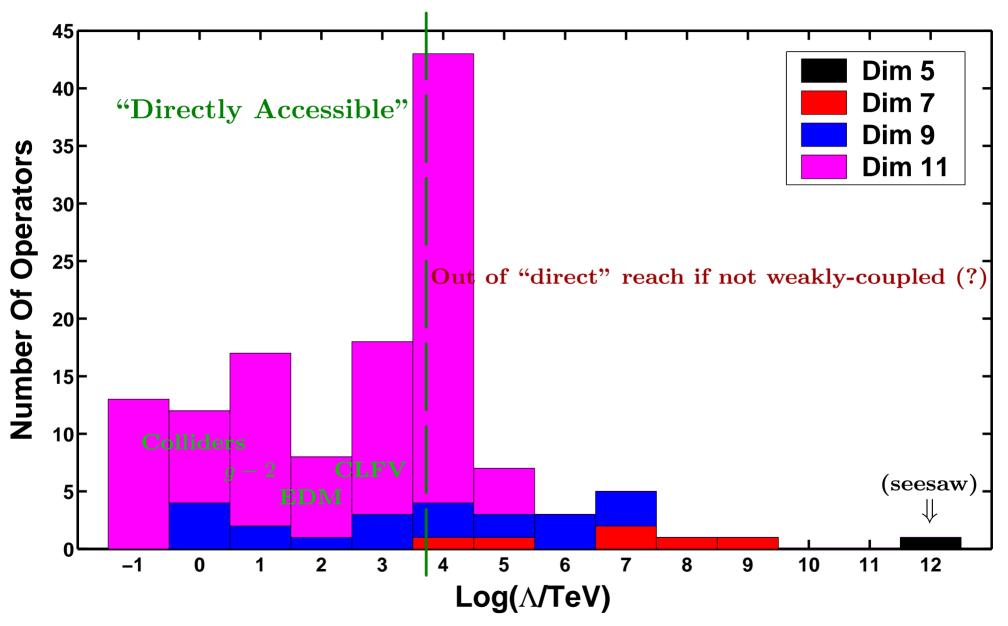

Equivalently, there are several completely different ways of addressing neutrino masses. The key issue is to understand what else the νSM candidates can do. [are they falsifiable?, are they "simple"?, do they address other outstanding problems in physics?, etc]

We need more experimental input.

Piecing the Neutrino Mass Puzzle

Understanding the origin of neutrino masses and exploring the new physics in the lepton sector will require unique **theoretical** and **experimental** efforts ...

- understanding the fate of lepton-number. Neutrinoless double-beta decay. What else?
- A comprehensive long baseline neutrino program. (On-going T2K, NO ν A, etc. DUNE and HyperK next steps towards the ultimate "superbeam" experiment.)
- Different baselines and detector technologies a must for both over-constraining the system and looking for new phenomena.
- Probes of neutrino properties, including neutrino scattering experiments. And what are the neutrino masses anyway? Kinematical probes.
- Precision measurements of charged-lepton properties (g-2, edm) and searches for rare processes $(\mu \to e\text{-conversion})$ the best bet at the moment).
- Collider experiments. The LHC and beyond may end up revealing the new physics behind small neutrino masses.
- Neutrino properties affect, in a significant way, the history of the universe (Cosmology). Will we learn about neutrinos from cosmology, or about cosmology from neutrinos?

January 25, 2021 _

New ν Phys

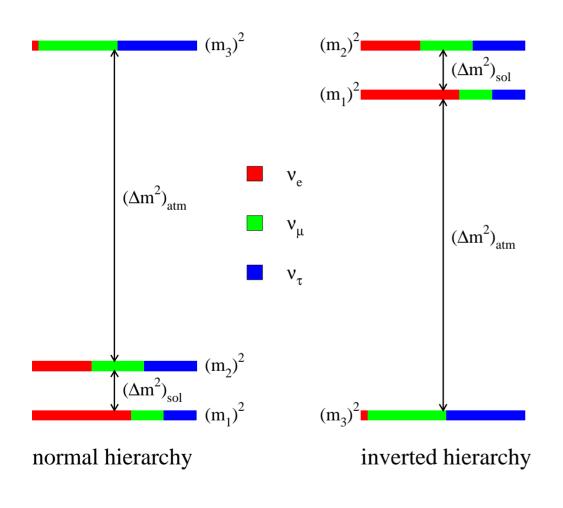

André de Gouvêa	N	orthwestern

HOWEVER...

We have only ever objectively "seen" neutrino masses in long-baseline oscillation experiments. It is one unambiguous way forward!

Does this mean we will reveal the origin of neutrino masses with oscillation experiments? We don't know, and we won't know until we try!

New Neutrino Oscillation Experiments: Missing Oscillation Parameters

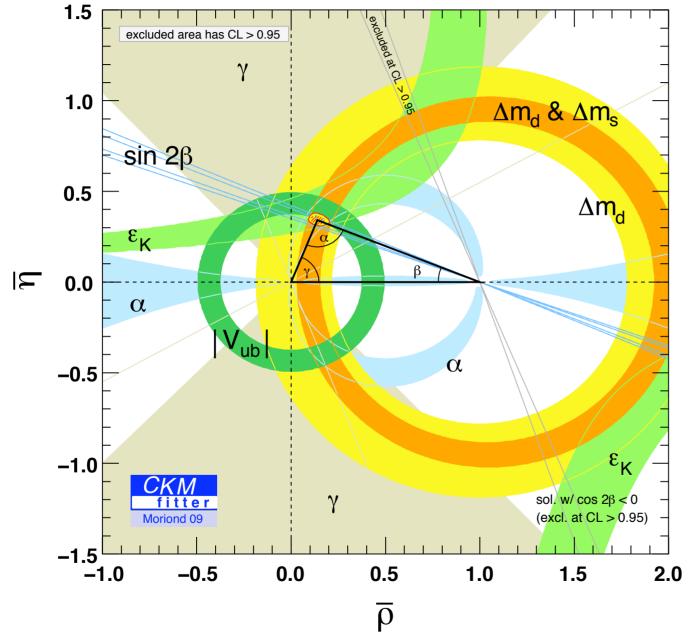

- What is the ν_e component of ν_3 ? $(\theta_{13} \neq 0!)$
- Is CP-invariance violated in neutrino oscillations? $(\delta \neq 0, \pi?)$
- Is ν_3 mostly ν_{μ} or ν_{τ} ? $(\theta_{23} > \pi/4, \theta_{23} < \pi/4, \text{ or } \theta_{23} = \pi/4?)$
- What is the neutrino mass hierarchy? $(\Delta m_{13}^2 > 0?)$
- ⇒ All of the above can "only" be addressed with new neutrino oscillation experiments

Ultimate Goal: Not Measure Parameters but Test the Formalism (Over-Constrain Parameter Space)

January 25, 2021 ______ New ν Phys

What we ultimately want to achieve:

We need to do <u>this</u> in the lepton sector!

$$\begin{pmatrix} \nu_e \\ \nu_{\mu} \\ \nu_{\tau} \end{pmatrix} = \begin{pmatrix} U_{e1} & U_{e2} & U_{e3} \\ U_{\mu 1} & U_{\mu 2} & U_{\mu 3} \\ U_{\tau 1} & U_{\tau 2} & U_{\tau 3} \end{pmatrix} \begin{pmatrix} \nu_1 \\ \nu_2 \\ \nu_3 \end{pmatrix}$$

What we have **really measured** (very roughly):

- Two mass-squared differences, at several percent level many probes;
- $|U_{e2}|^2$ solar data;
- $|U_{\mu 2}|^2 + |U_{\tau 2}|^2 \text{solar data};$
- $|U_{e2}|^2 |U_{e1}|^2 \text{KamLAND};$
- $|U_{\mu 3}|^2(1-|U_{\mu 3}|^2)$ atmospheric data, K2K, MINOS;
- $|U_{e3}|^2(1-|U_{e3}|^2)$ Double Chooz, Daya Bay, RENO;
- $|U_{e3}|^2 |U_{\mu 3}|^2$ (upper bound \rightarrow evidence) MINOS, T2K.

We still have a ways to go!

What Could We Run Into?

since $m_{\nu} \neq 0$ and leptons mix . . .

January 25, 2021 ______ New $\,
u$ Phys

What Could We Run Into?

- New neutrino states. In this case, the 3×3 mixing matrix would not be unitary.
- New short-range neutrino interactions. These lead to, for example, new matter effects. If we don't take these into account, there is no reason for the three flavor paradigm to "close."
- New, unexpected neutrino properties. Do they have nonzero magnetic moments? Do they decay? The answer is 'yes' to both, but nature might deviate dramatically from νSM expectations.
- Weird stuff. CPT-violation. Decoherence effects (aka "violations of Quantum Mechanics.")
- etc.

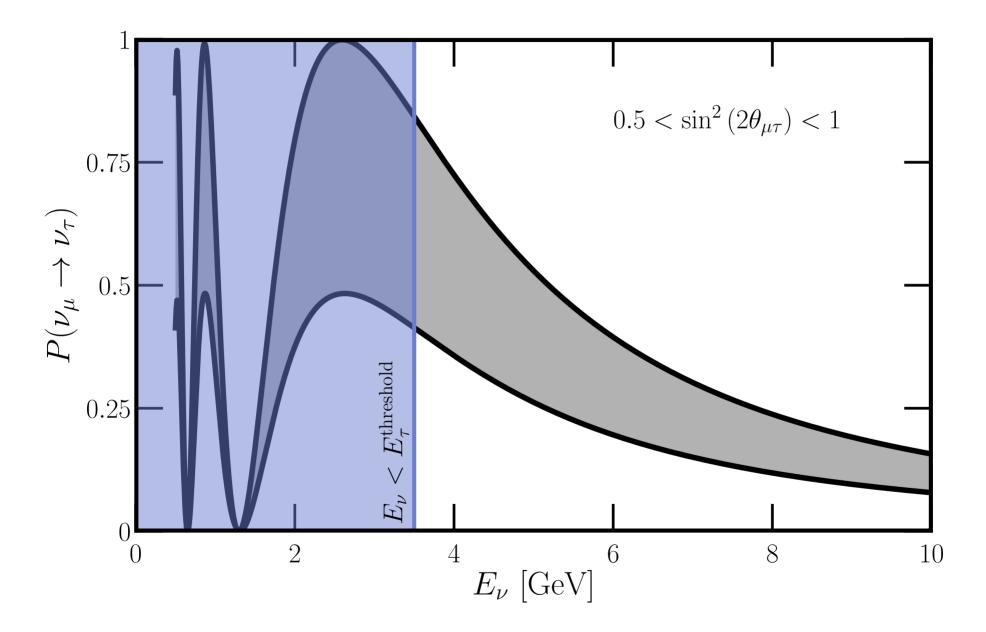

Physics with Beam ν_{τ} 's at the DUNE Far Detector Site

[AdG, Kelly, Pasquini, Stenico, arXiv:1904.07265]

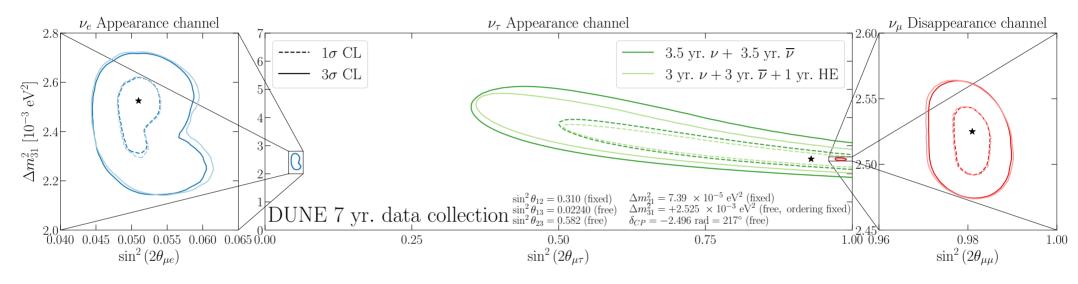

ν_{τ} sample: why?

- Model independent checks.
 - Establishing the existence of ν_{τ} in the beam;
 - Is it consistent with the oscillation interpretation $\nu_{\mu} \rightarrow \nu_{\tau}$?
 - Measuring the oscillation parameters.
 - Comparison to OPERA, atmospheric samples.
- Cross-section measurements.
 - Comparison to OPERA, atmospheric samples.
- Testing the 3-neutrinos paradigm.
 - Independent measurement of the oscillation parameters.
 - More concretely: "unitarity triangle"-like test.
 - Is there anything the ν_{τ} sample brings to the table given the ν_{μ} , ν_{e} , and neutral current samples? [model-dependent]

January 25, 2021 _______ New ν Phys

Testing the Three-Massive-Neutrinos Paradigm

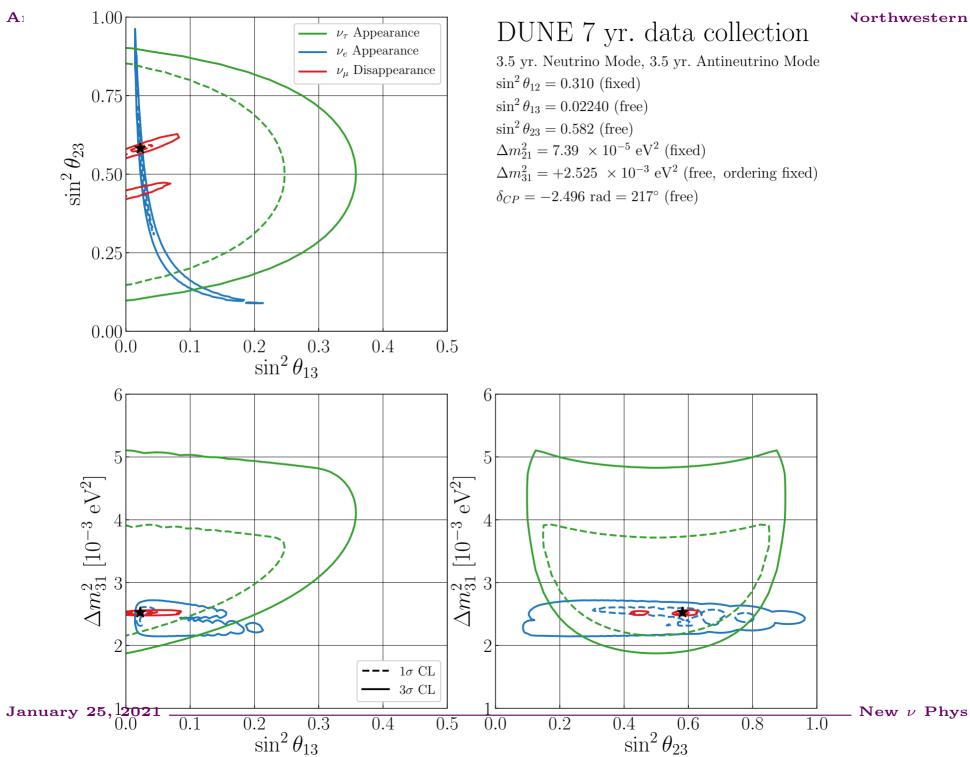

$$\sin^2 2\theta_{\mu e} \equiv 4|U_{\mu 3}|^2|U_{e 3}|^2, \quad \sin^2 2\theta_{\mu \tau} \equiv 4|U_{\mu 3}|^2|U_{\tau 3}|^2, \quad \sin^2 2\theta_{\mu \mu} \equiv 4|U_{\mu 3}|^2(1-|U_{\mu 3}|^2)$$

Unitarity Test:
$$|U_{e3}|^2 + |U_{\mu 3}|^2 + |U_{\tau 3}|^2 = 1_{-0.06}^{+0.05}$$
 [one sigma] $(1_{-0.17}^{+0.13}$ [three sigma])

Case Studies

I will discuss a few case-studies, including the fourth-neutrino hypothesis and non-standard neutral-current neutrino—matter interactions. In general

- I will mostly discuss, for concreteness, the DUNE setup;
- I don't particularly care about how likely, nice, or contrived the scenarios are. It is useful to consider them as well-defined ways in which the three-flavor paradigm can be violated. They can be used as benchmarks for comparing different efforts, or, perhaps, as proxies for other new phenomena.
- I will mostly be interested in three questions:
 - How sensitive are next-generation long-baseline efforts?;
 - How well they can measure the new-physics parameters, including new sources of CP-invariance violation?;
 - Can they tell different new-physics models apart?

A Fourth Neutrino

(Berryman et al, arXiv:1507.03986)

If there are more neutrinos with a well-defined mass, it is easy to extend the paradigm:

$$\begin{pmatrix} \nu_{e} \\ \nu_{\mu} \\ \nu_{\tau} \\ \nu_{?} \\ \vdots \end{pmatrix} = \begin{pmatrix} U_{e1} & U_{e2} & U_{e3} & U_{e4} & \cdots \\ U_{\mu 1} & U_{\mu 2} & U_{\mu 3} & U_{\mu 4} & \cdots \\ U_{\tau 1} & U_{\tau 2} & U_{\tau 3} & U_{\tau 4} & \cdots \\ U_{?1} & U_{?2} & U_{?3} & U_{?4} & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix} \begin{pmatrix} \nu_{1} \\ \nu_{2} \\ \nu_{3} \\ \nu_{4} \\ \vdots \end{pmatrix}$$

- New mass eigenstates easy: ν_4 with mass m_4 , ν_5 with mass m_5 , etc.
- What are these new "flavor" (or weak) eigenstates $\nu_?$? Here, the answer is we don't care. We only assume there are no new accessible interactions associated to these states.

$$U_{e2} = s_{12}c_{13}c_{14},$$

$$U_{e3} = e^{-i\eta_1}s_{13}c_{14},$$

$$U_{e4} = e^{-i\eta_2}s_{14},$$

$$U_{\mu 2} = c_{24}\left(c_{12}c_{23} - e^{i\eta_1}s_{12}s_{13}s_{23}\right) - e^{i(\eta_2 - \eta_3)}s_{12}s_{14}s_{24}c_{13},$$

$$U_{\mu 3} = s_{23}c_{13}c_{24} - e^{i(\eta_2 - \eta_3 - \eta_1)}s_{13}s_{14}s_{24},$$

$$U_{\mu 4} = e^{-i\eta_3}s_{24}c_{14},$$

$$U_{\tau 2} = c_{34}\left(-c_{12}s_{23} - e^{i\eta_1}s_{12}s_{13}c_{23}\right) - e^{i\eta_2}c_{13}c_{24}s_{12}s_{14}s_{34} - e^{i\eta_3}\left(c_{12}c_{23} - e^{i\eta_1}s_{12}s_{13}s_{23}\right)s_{24}s_{34},$$

$$U_{\tau 3} = c_{13}c_{23}c_{34} - e^{i(\eta_2 - \eta_1)}s_{13}s_{14}s_{34}c_{24} - e^{i\eta_3}s_{23}s_{24}s_{34}c_{13},$$

$$U_{\tau 4} = s_{34}c_{14}c_{24}.$$

When the new mixing angles ϕ_{14} , ϕ_{24} , and ϕ_{34} vanish, one encounters oscillations among only three neutrinos, and we can map the remaining parameters $\{\phi_{12}, \phi_{13}, \phi_{23}, \phi_{13}, \phi_{13}, \phi_{23}, \phi_{13}, \phi_{13}, \phi_{23}, \delta_{CP}\}$.

Also

$$\eta_s \equiv \eta_2 - \eta_3$$

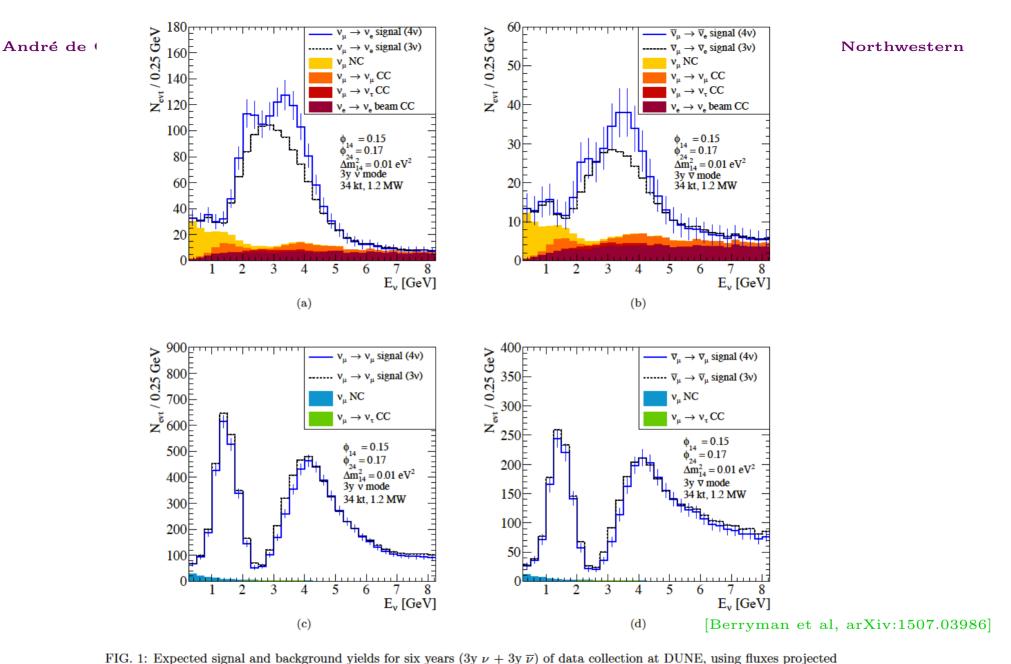

is the only new CP-odd parameter to which oscillations among ν_e and ν_μ are sensitive.

January 25, 2021 -

 $_$ New ν Phys

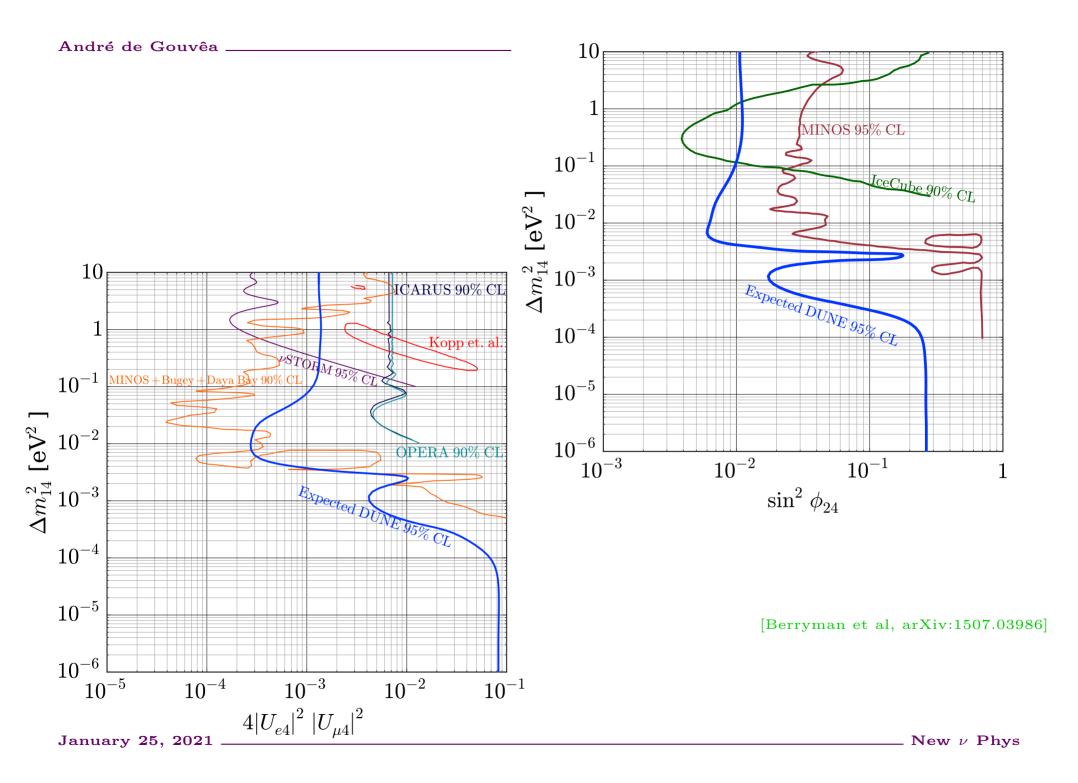

Some technicalities for the aficionados

- 34 kiloton liquid argon detector;
- 1.2 MW proton beam on target as the source of the neutrino and antineutrino beams, originating 1300 km upstream at Fermilab;
- 3 years each with the neutrino and antineutrino mode;
- Include standard backgrounds, and assume a 5% normalization uncertainty;
- Whenever quoting bounds or measurements of anything, we marginalize over all parameters not under consideration;
- We include priors on Δm_{12}^2 and $|U_{e2}|^2$ in order to take into account information from solar experiments and KamLAND. Unless otherwise noted, we assume the mass ordering is normal;
- We do not include information from past experiments. We assume that DUNE will "out measure" all experiments that came before it (except for the solar ones, as mentioned above).

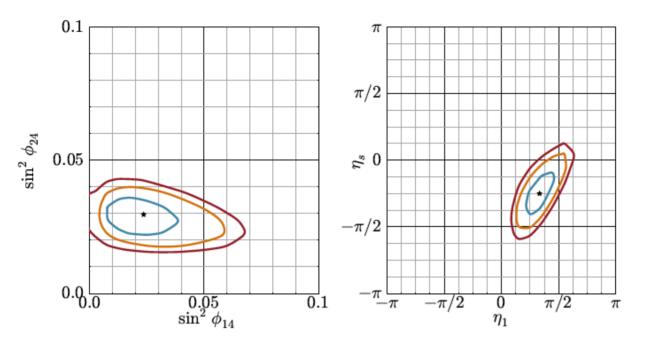

by Ref. [1], for a 34 kiloton detector, and a 1.2 MW beam. (a) and (b) show appearance channel yields for neutrino and antineutrino beams, respectively, while (c) and (d) show disappearance channel yields. The 3ν signal corresponds to the standard three-neutrino hypothesis, where $\sin^2\theta_{12}=0.308$, $\sin^2\theta_{13}=0.0235$, $\sin^2\theta_{23}=0.437$, $\Delta m_{12}^2=7.54\times 10^{-5} \text{ eV}^2$, $\Delta m_{13}^2=2.43\times 10^{-3} \text{ eV}^2$, $\delta_{CP}=0$, while the 4ν signal corresponds to $\sin^2\phi_{12}=0.315$, $\sin^2\phi_{13}=0.024$, $\sin^2\phi_{23}=0.456$, $\sin^2\phi_{24}=0.023$, $\sin^2\phi_{24}=0.030$, $\Delta m_{14}^2=10^{-2} \text{ eV}^2$, $\eta_1=0$, and $\eta_s=0$. Statistical uncertainties are shown as vertical bars in each bin. Backgrounds are defined in the text and are assumed to be identical for the three- and four-neutrino scenarios: any discrepancy is negligible after accounting for a 5% normalization uncertainty.

TABLE I: Input values of the parameters for the three scenarios considered for the four-neutrino hypothesis. Values of ϕ_{12} , ϕ_{13} , and ϕ_{23} are chosen to be consistent with the best-fit values of $|U_{e2}|^2$, $|U_{e3}|^2$, and $|U_{\mu3}|^2$, given choices of ϕ_{14} and ϕ_{24} . Here, $\eta_s \equiv \eta_2 - \eta_3$. Note that Δm_{14}^2 is explicitly assumed to be positive, i.e., $m_4^2 > m_1^2$.

And

[Berryman et al, arXiv:1507.03986]

FIG. 6: Expected sensitivity contours at 68.3% (blue), 95% (orange), and 99% (red) CL at DUNE with six years of data collection (3y ν + 3y $\overline{\nu}$), a 34 kiloton detector, and a 1.2 MW beam given the existence of a fourth neutrino with parameters from Case 3 in Table I. Results from solar neutrino experiments are included here as Gaussian priors for the values of $|U_{e2}|^2 = 0.301 \pm 0.015$ and $\Delta m_{12}^2 = 7.54 \pm 0.24 \times 10^{-5} \text{ eV}^2$ [22].

Non-Standard Neutrino Interactions (NSI)

Effective Lagrangian:

$$\mathcal{L}^{\text{NSI}} = -2\sqrt{2}G_F(\bar{\nu}_{\alpha}\gamma_{\rho}\nu_{\beta}) \sum_{f=e,u,d} (\epsilon_{\alpha\beta}^{fL} \overline{f}_L \gamma^{\rho} f_L + \epsilon_{\alpha\beta}^{fR} \overline{f}_R \gamma^{\rho} f_R) + h.c.,$$

For oscillations,

$$H_{ij} = \frac{1}{2E_{\nu}} \operatorname{diag} \left\{ 0, \Delta m_{12}^2, \Delta m_{13}^2 \right\} + V_{ij},$$

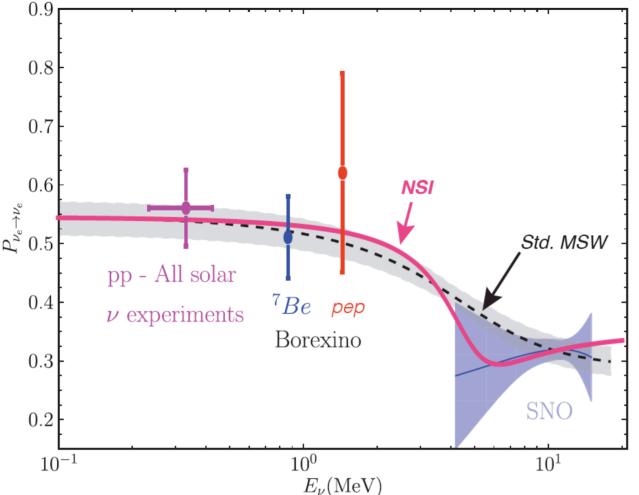

where

$$V_{ij} = U_{i\alpha}^{\dagger} V_{\alpha\beta} U_{\beta j},$$

$$V_{\alpha\beta} = A \begin{pmatrix} 1 + \epsilon_{ee} & \epsilon_{e\mu} & \epsilon_{e\tau} \\ \epsilon_{e\mu}^* & \epsilon_{\mu\mu} & \epsilon_{\mu\tau} \\ \epsilon_{e\tau}^* & \epsilon_{\mu\tau}^* & \epsilon_{\tau\tau} \end{pmatrix},$$

 $A = \sqrt{2}G_F n_e$. $\epsilon_{\alpha\beta}$ are linear combinations of the $\epsilon_{\alpha\beta}^{fL,R}$. Important: I will discuss propagation effects only and ignore NSI effects in production or detection (ϵ versus ϵ^2).

Solar Neutrinos

We are not done yet!

- see "vaccum-matter" transition
- probe for new physics: NSI, pseudo-Dirac, . . .
- probe of the solar interior!

 "solar abundance problem"

 (see e.g. 1104.1639)

'CNO neutrinos may provide information on planet formation!'

FIG. 1: Recent SNO solar neutrino data [18] on $P(v_e \rightarrow v_e)$ (blue line with 1 σ band). The LMA MSW solution (dashed black curve with gray 1 σ band) appears divergent around a few MeV, whereas for NSI with $\varepsilon_{e\tau} = 0.4$ (thick magenta), the electron neutrino probability appears to fit the data better. The data points come from the recent Borexing paper [19].

How Do We Learn More – Different Experiments!

- Different L and E, same L/E (e.g. HyperK versus DUNE);
- Different matter potentials (e.g. atmosphere versus accelerator);
- Different oscillation modes (appearance versus disappearance, e's, μ 's and τ 's).

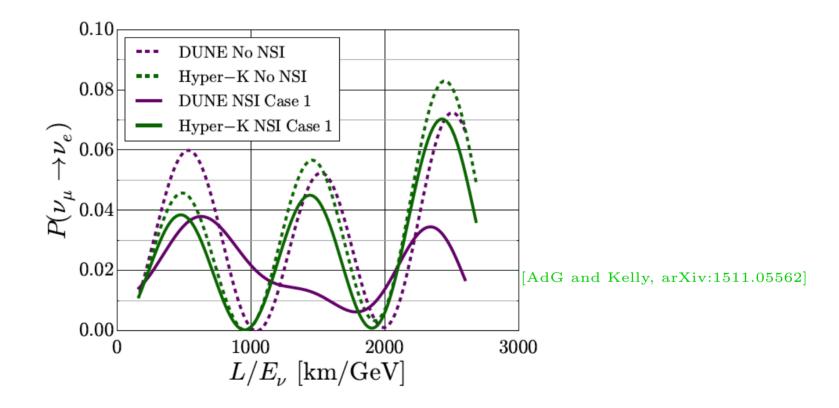

FIG. 9: Oscillation probabilities for three-neutrino (dashed) and NSI (solid) hypotheses as a function of L/E_{ν} , the baseline length divided by neutrino energy, for the DUNE (purple) and HyperK (green) experiments. Here, $\delta = 0$ and the three-neutrino parameters used are consistent with Ref. [47].

The Physics Behind NSI – Comments and Concerns

There are two main questions associated to NSI's. They are somewhat entwined.

- 1. What is the new physics that leads to neutrino NSI? or are there models for new physics that lead to large NSIs? Are these models well motivated? Are they related to some of the big questions in particle physics?
- 2. Are NSIs constrained by observables that have nothing to do with neutrino physics? Are large NSI effects allowed at all?

Effective Lagrangian:

$$\mathcal{L}^{\text{NSI}} = -2\sqrt{2}G_F \epsilon^{\alpha\beta} (\bar{\nu}_{\alpha}\gamma_{\rho}\nu_{\beta}) (\bar{f}\gamma^{\rho}f).$$

This is not $SU(2)_L$ invariant. Let us fix that:

$$\mathcal{L}^{\text{NSI}} = -2\sqrt{2}G_F \epsilon^{\alpha\beta} (\bar{L}_{\alpha}\gamma_{\rho}L_{\beta}) (\bar{f}\gamma^{\rho}f).$$

where $L = (\nu, \ell^-)^T$ is the lepton doublet. This is a big problem. Charged-Lepton flavor violating constraints are really strong (think $\mu \to e^+e^-e^+$, $\mu \to e$ -conversion, $\tau \to \mu$ +hadrons, etc), and so are most of the flavor diagonal charged-lepton effects.

There are a couple of ways to circumvent this...

1. Dimension-Eight Effective Operator

$$\mathcal{L}^{\text{NSI}} = -2\sqrt{2}G_F \epsilon^{\alpha\beta} (\bar{\nu}_{\alpha}\gamma_{\rho}\nu_{\beta}) (\bar{f}\gamma^{\rho}f).$$

This is not $SU(2)_L$ invariant. Let us fix that in a different way

$$\mathcal{L}^{\text{NSI}} = -2\sqrt{2}G_F \frac{\epsilon^{\alpha\beta}}{v^2} ((HL)^{\dagger}_{\alpha} \gamma_{\rho} (HL)_{\beta}) (\overline{f} \gamma^{\rho} f).$$

where $HL \propto H^+\ell^- - H^0\nu$. After electroweak symmetry breaking $H^0 \to v + h^0$ and we only get new neutrino interactions.

Sadly, it is not that simple. At the one-loop level, the dimension-8 operator will contribute to the dimension-6 operator in the last page, as discussed in detail in [Gavela *et al*, arXiv:0809.3451 [hep-ph]]. One can, however, fine-tune away the charged-lepton effects.

January 25, 2021 _____

2. Light Mediator

(Recent overview: Y. Farzan and M. Tórtola, arXiv:1710.09360 [hep-ph])

$$\mathcal{L}^{\text{NSI}} = -2\sqrt{2}G_F \epsilon^{\alpha\beta} (\bar{\nu}_{\alpha}\gamma_{\rho}\nu_{\beta}) (\bar{f}\gamma^{\rho}f).$$

This may turn out to be a good effective theory for neutrino propagation but a bad effective theory for most charged-lepton processes. I.e.

$$\mathcal{L}^{\text{NSI}} = -2\sqrt{2}G_F \epsilon^{\alpha\beta} (\bar{L}_{\alpha}\gamma_{\rho}L_{\beta}) (\bar{f}\gamma^{\rho}f).$$

might be inappropriate for describing charged-lepton processes if the particle we are integrating out is light (as in lighter than the muon).

Charged-lepton processes are "watered down." Very roughly

$$\epsilon \to \epsilon \left(\frac{m_{Z'}}{m_\ell}\right)^2$$

where $m_{Z'}$ is the mass of the particle mediating the new interaction, and m_{ℓ} is the mass associated to the charged-lepton process of interest.

Different Oscillation Parameters for Neutrinos and Antineutrinos?

[AdG, Kelly, arXiv:1709.06090]

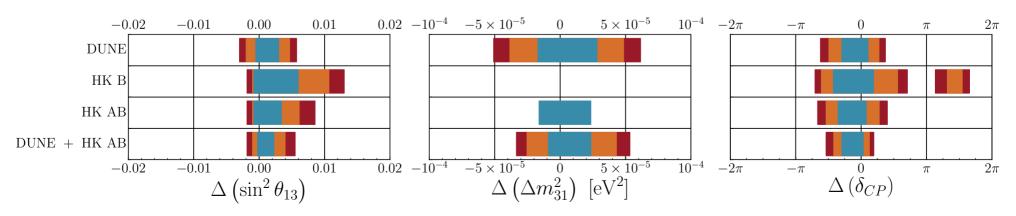

- How much do we know, independently, about neutrino and antineutrino oscillations?
- What happens if the parameters disagree?

[AdG and Kelly, arXiv:1709.06090]

New ν Phys

Other Opportunities (Very Brief)

- Near-Detector New Physics: Long-baseline experiments will collect large samples of neutrino—nucleus and neutrino—electron scattering events. These allow, for example, high-precision measurements of the the Weinberg angle (see, e.g., AdG et al, 1912.06658). They are also beam-dump-like experiments with an enormous detector a great place to look for new very weakly coupled states including heavy neutrinos (HNL), hidden-sector particles (ALPs) (see, e.g. Berryman et al, 1912.07622) and the physics responsible for DM, etc.
- Supernova Neutrinos: Type-II supernova explosions are an intense source of neutrinos. It allows one to constrain neutrino properties to which we don't have access in the laboratory, including new physics associates to neutrino decays (see, e.g., AdG et al, 1910.01127 or the presence of new oscillations associated to tiny mass-squared differences, the so-called pseudo-Dirac neutrino scenario.

André de Gouvêa	J	Northwestern

In Conclusion

The venerable Standard Model sprung a leak in the end of the last century (and we are still trying to patch it): neutrinos are not massless!

- 1. We still **know very little** about the new physics uncovered by neutrino oscillations.
- 2. **neutrino masses are very small** we don't know why, but we think it means something important.
- 3. **neutrino mixing is "weird"** we don't know why, but we think it means something important.

January 25, 2021 _______ New ν Phys

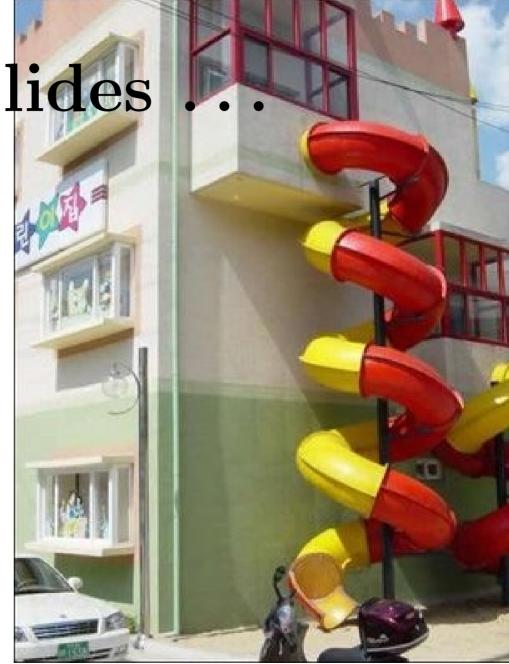

- 4. We need more experimental input These will come from a rich, diverse experimental program which relies heavily on the existence of underground facilities capable of hosting large detectors (double-beta decay, precision neutrino oscillations, supernova neutrinos, proton decay, etc).
- 5. Precision measurements of neutrino oscillations are sensitive to several new phenomena, including new neutrino properties, the existence of new states, or the existence of new interactions. There is a lot of work to be done when it comes to understanding which new phenomena can be probed in long-baseline oscillation experiments (and how well) and what are the other questions one can ask related and unrelated to neutrinos of these unique particle physics experiments.
- 6. There is plenty of **room for surprises**, as neutrinos are potentially very deep probes of all sorts of physical phenomena. Remember that neutrino oscillations are "quantum interference devices" potentially very sensitive to whatever else may be out there (e.g., $\Lambda \simeq 10^{14} \text{ GeV}$).

Not all is well(?): The Short Baseline Anomalies

Different data sets, sensitive to L/E values small enough that the known oscillation frequencies do not have "time" to operate, point to unexpected neutrino behavior. These include

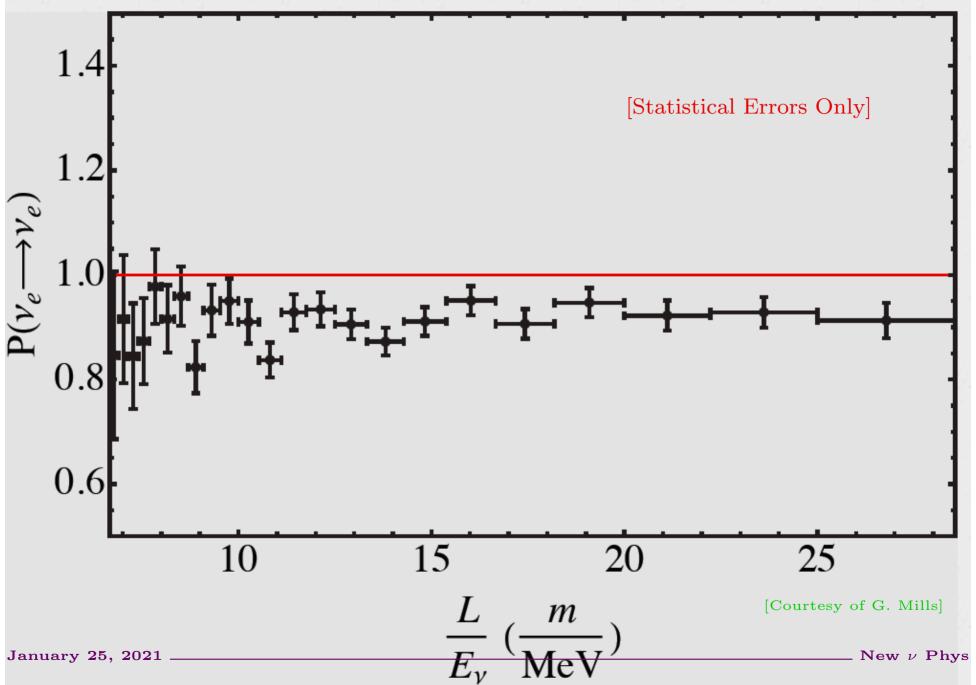

- $\nu_{\mu} \rightarrow \nu_{e}$ appearance LSND, MiniBooNE;
- $\nu_e \rightarrow \nu_{\text{other}}$ disappearance radioactive sources;
- $\bar{\nu}_e \to \bar{\nu}_{\text{other}}$ disappearance reactor experiments.

None are entirely convincing, either individually or combined. However, there may be something very very interesting going on here...

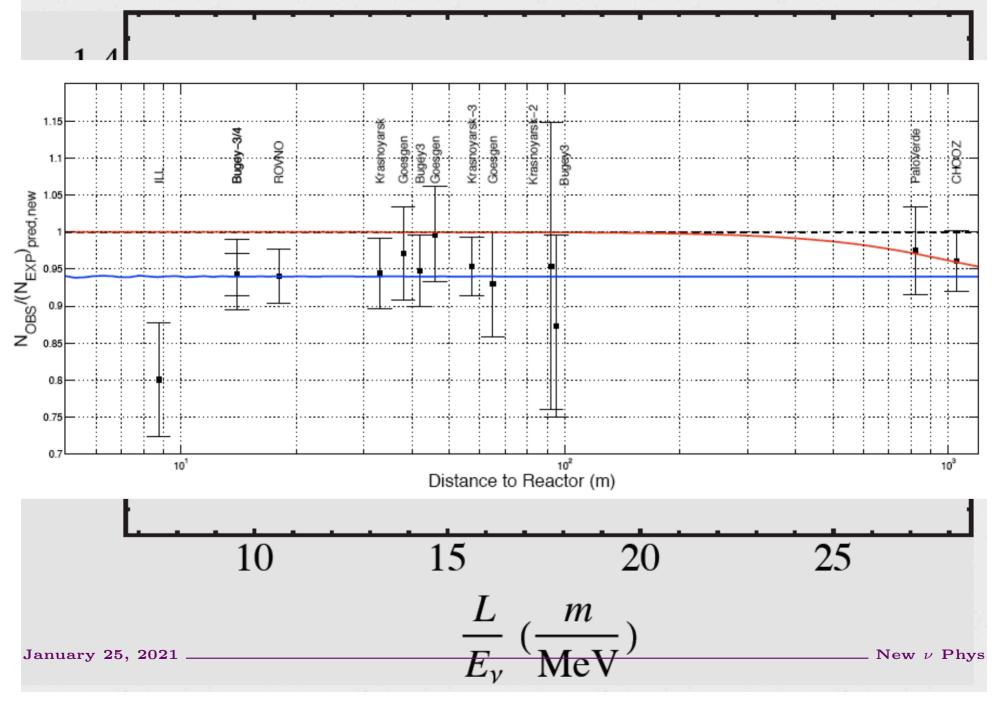

New ν Phys

January 25, 2021

Bugey 40 m

Bugey 40 m

What is Going on Here?

- Are these "anomalies" related?
- Is this neutrino oscillations, other new physics, or something else?
- Are these related to the origin of neutrino masses and lepton mixing?
- How do clear this up **definitively**?

Need new clever experiments, of the short-baseline type!

Observable wish list:

- ν_{μ} disappearance (and antineutrino);
- ν_e disappearance (and antineutrino);
- $\nu_{\mu} \leftrightarrow \nu_{e}$ appearance;
- $\nu_{\mu,e} \to \nu_{\tau}$ appearance.

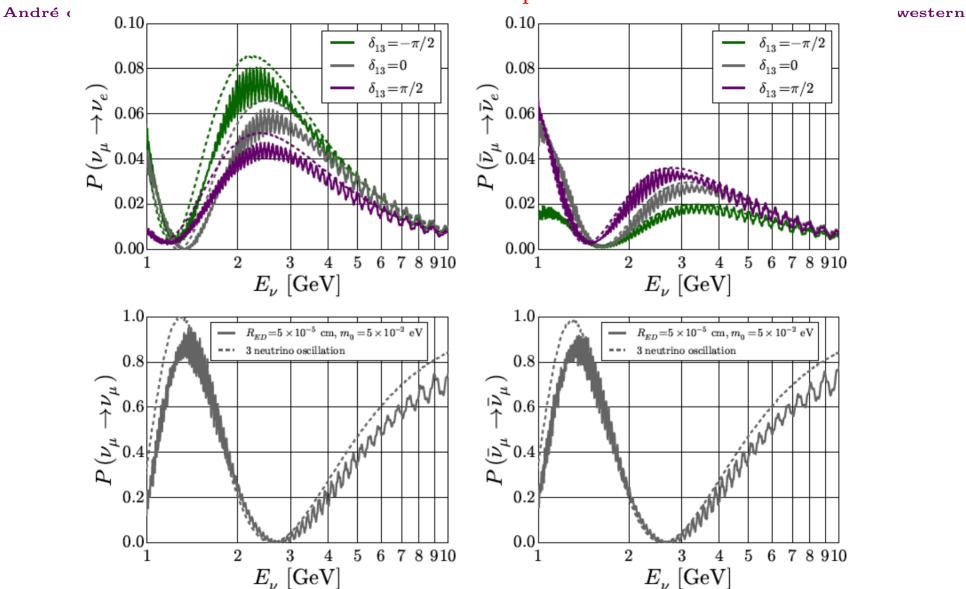

FIG. 1: Oscillation probabilities assuming a three-neutrino framework (dashed) and an LED hypothesis with $m_0 = 5 \times 10^{-2}$ eV and $R_{\rm ED}^{-1} = 0.38$ eV ($R_{\rm ED} = 5 \times 10^{-5}$ cm), for the normal neutrino mass hierarchy, ar Xiv:1603.00018] $\Delta m_{13}^2 > 0$. The values of the other oscillation parameters are tabulated in Table I, see text for details. The top row displays appearance probabilities $P(\nu_{\mu} \to \nu_{e})$ (left) and $P(\bar{\nu}_{\mu} \to \bar{\nu}_{e})$ (right), and has curves shown January for $\delta_{13} = 0$ (gray), and $\delta_{13} = \pi/2$ (purple). The bottom row displays disappearance ν Phys probabilities $P(\nu_{\mu} \to \nu_{\mu})$ (left) and $P(\bar{\nu}_{\mu} \to \bar{\nu}_{\mu})$ (right).

Another Model: Can Neutrino Oscillation Experiments Discover A Fifth Dimension?

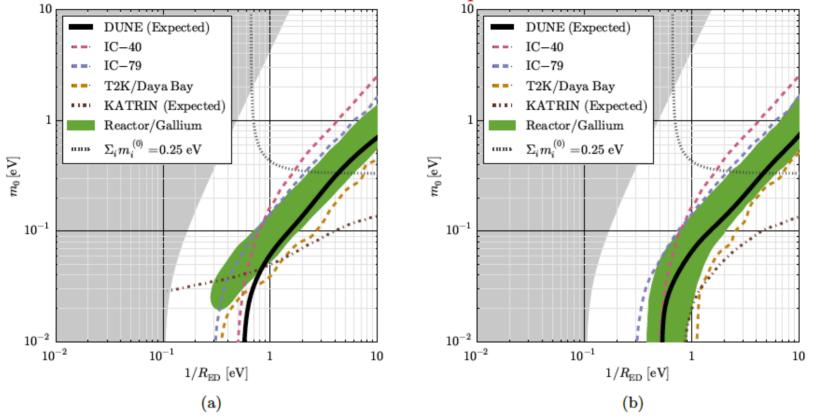

FIG. 3: Exclusion limits in the $R_{\rm ED}^{-1}$ - m_0 plane, assuming either (a) a normal hierarchy or (b) an inverted hierarchy of neutrino masses. The exclusion regions are to the top-left of the relevant curves. Shown are the 95% CL lines from DUNE (black), IceCube-40 (mauve) and Ice-Cube79 (blue) [20], and a combined analysis of T2K and Daya Bay (gold) [18]. We also include the 90% CL line from sensitivity analysis of KATRIN (burgundy) [16]. The shaded green regions are preferred at 95% CL by the reactor anomaly seen in reactor and Gallium experiments [19]. The gray shaded regions are excluded by the measurements of Δm_{i1}^2 , as explained in the text. The dotted gray lines are curves along which $\sum_i m_i^{(0)} = 0.25$ eV. Higher values of $\sum_i m_i^{(0)}$ correspond to the regions above and to the right of the dotted gray lines.

Another Model: Can Neutrino Oscillation Experiments Discover A Fifth Dimension?

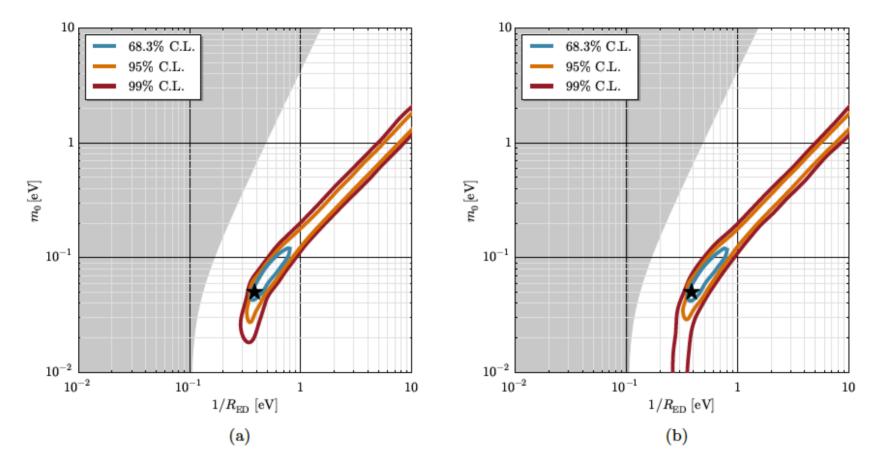

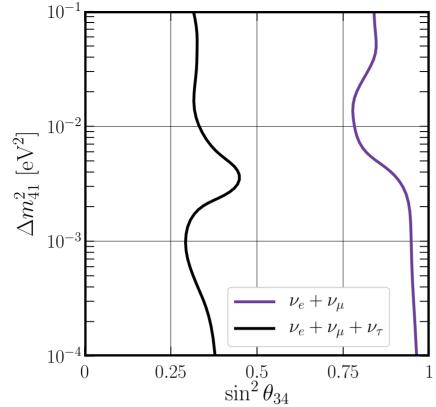

FIG. 4: Expected sensitivity to a non-zero set of LED parameters as measured by DUNE, assuming three years each of neutrino and antineutrino data collection. Fig. 4(a) assumes the normal mass hierarchy (NH) and Fig. 4(b) assumes the inverted mass hierarchy (IH). The LED parameters assumed here are $m_0 = 5 \times 10^{-2}$ eV and $R_{\rm ED}^{-1} = 0.38$ eV, while $\delta_{13} = \pi/3$. The input values of Δm_{i1}^2 , i = 1, 2 are in Table I. The input values for the mixing angles are, for the NH, $\sin^2 \theta_{12} = 0.322$, $\sin^2 \theta_{13} = 0.0247$, $\sin^2 \theta_{23} = 0.581$, and, for the IH, $\sin^2 \theta_{12} = 0.343$, $\sin^2 \theta_{13} = 0.0231$, $\sin^2 \theta_{23} = 0.541$.
