Dark Matter: many clues on many scales

From galactic scales...

... to cosmological scales.

What we do not know about Dark Matter

In the Λ CDM model, Dark Matter is a cold, collision-less, matter component, which interacts only through gravity with other species.

Most of its basic properties are unknown

- Is it made of a **single species**?
- Is it a **particle**? A fermion? A boson?
- If it is a particle, what is its **lifetime**?
- Does it have **non-gravitational interaction**?
- How was it **produced**?
- Is it the **same “dark matter”** from cosmological to galactic scales?
- and many more...

Searching for Dark Matter in cosmology

An analogy with the WIMP

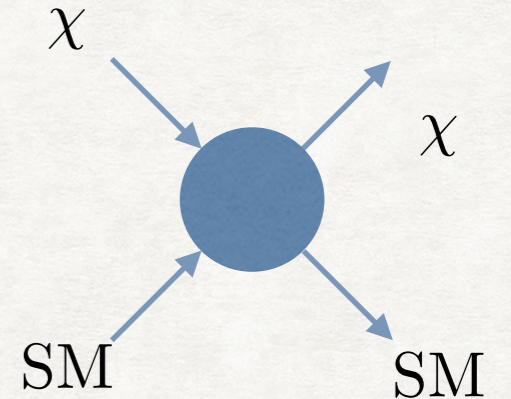

Production

Annihilation

Scattering

in particle physics

Collider

Indirect detection

Direct detection

in cosmology

Relic abundance

Energy injection

Momentum transfer

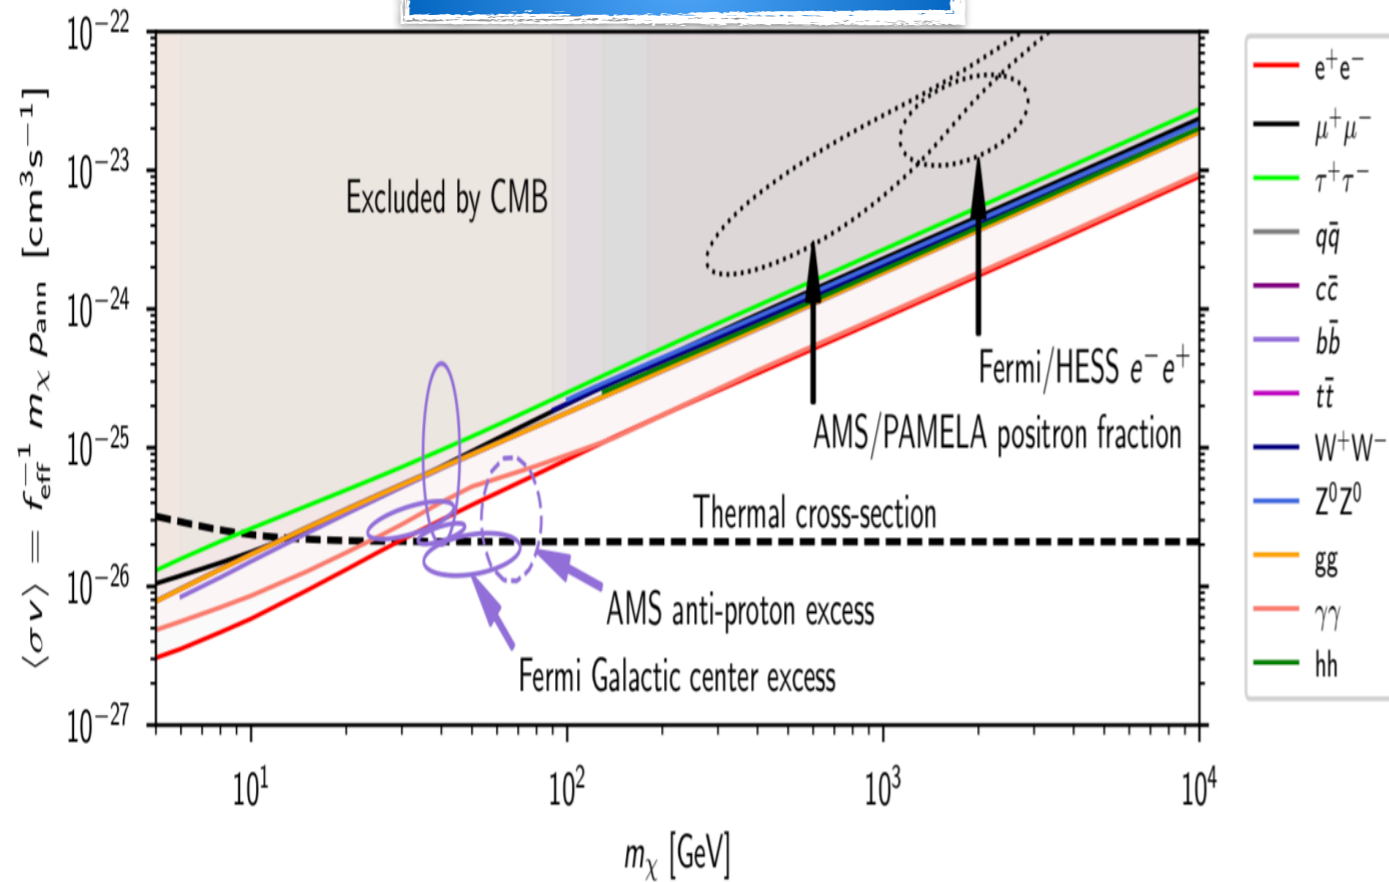

The strength of cosmology is its ability to constrain many different scenarios via the complementarity of various probes

(WIMP, axions, sterile neutrinos, Primordial Black holes...)

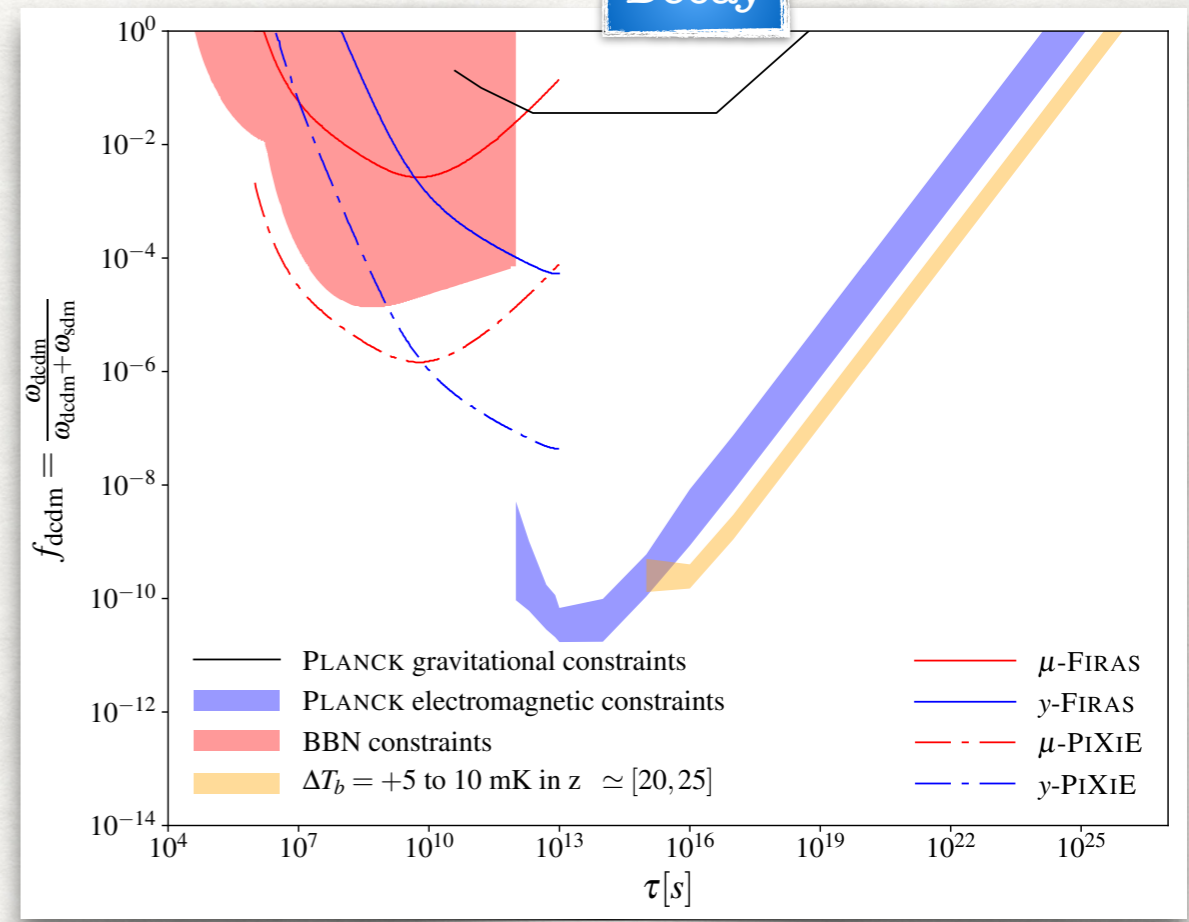

“Cosmic complementarity” over times

Electromagnetic energy injection of Dark Matter is strongly constrained by CMB and BBN.

Annihilation (s-wave)

Decay

- WIMP Dark Matter: CMB excludes thermal relics below $m < 10 - 30 \text{ GeV}$. Competitive with Fermi, AMS constraints.
- Decaying Dark Matter: CMB can constrain $f_{\text{dcdm}} \lesssim 10^{-10}$ at $z \sim 1000$! Complementarity with BBN $z < 2000$.
- Future: 21cm is an exquisite probe of DM thermal history. + CMB ‘spectral distortions’.
- e.g. EDGES: exotic 21cm signal *orders of magnitude* stronger than CMB to constrain DM annihilations/decays.
- Theoretical challenges: efficient methods to extract ‘cosmology’ from large astrophysical uncertainties.

“Cosmic complementarity” over scales and times

Gravitational signature: the nature of Dark Matter impact the behavior at small scales

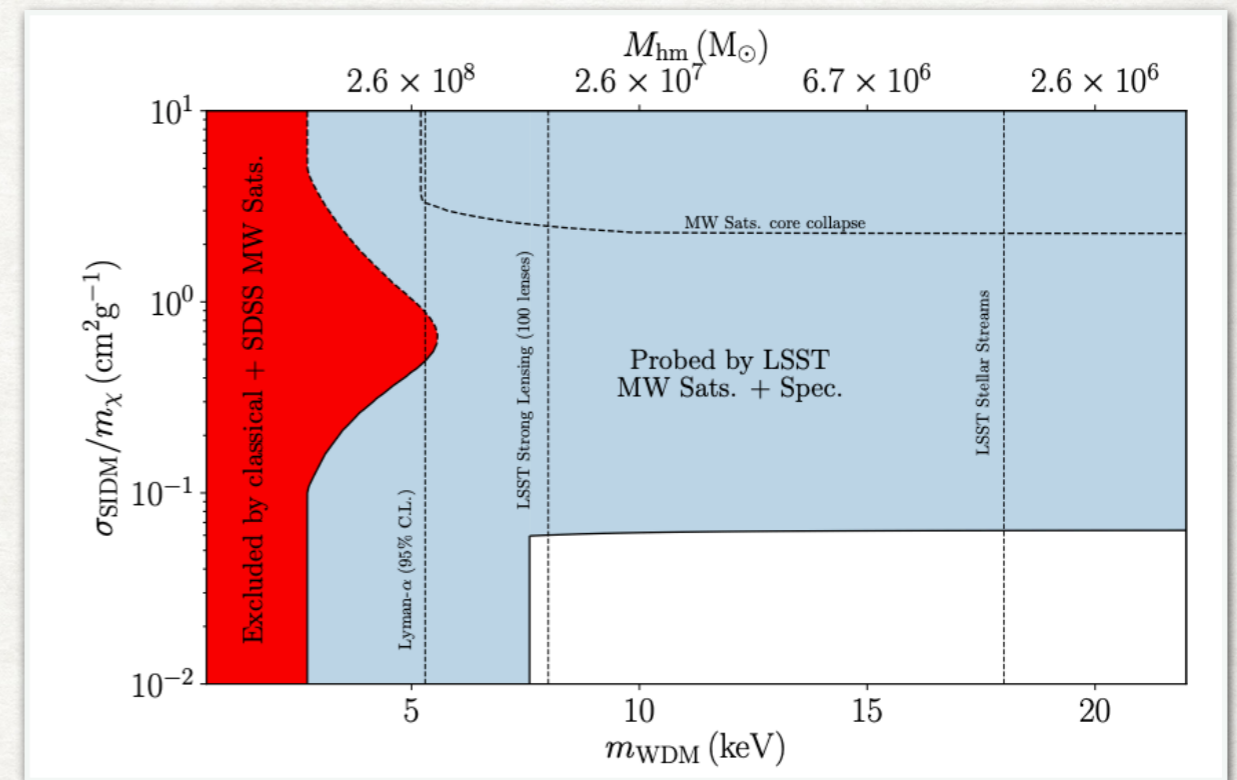

- Large scales: CMB measured to ‘cosmic-variance’ until $\ell \lesssim 2500$ by Planck. (+ACT+SPT extend to 5000)
- Intermediate scales: CMB lensing, Galaxy clustering and weak lensing to few % precision.
- Small-scales: Dwarf satellite count and Ly α strongest at small scales.
- Canonical bounds from Ly α to date: $m_{\text{wdm}} \gtrsim 3 - 5 \text{ keV}$, $m_a > 2 \times 10^{-20} \text{ eV}$. Important for ‘small-scale crisis’.
Irsic++ 1702.01764, Rogers&Peiris 2007.12705
- Future: Great complementarity between CMB-S4 & Euclid / LSST (Vera Rubin Obs) & 21 cm probes (SKA).
- Theoretical challenges: accurate modeling of small-scale physics + statistical analysis. Nbody? EFT of LSS?

Complementarity with laboratory constraints

Direct detection: Dark Matter scattering also suppresses power at small-scales and the number of sub halos

LSST working group 1902.01055

- Direct DM detectors are shielded and insensitive to ‘strongly’ interacting dark matter; velocity-dependent interaction. *Boddy & Gluscevic, 1712.07133, 1801.08609, Enken and Kouvaris 1802.04764*
- Strong DM-baryon or DM-DM self interaction can impact the small-scale matter power spectrum and suppress the number of sub-halos. *Nadler et al. 1904.10000*
- LSST, Euclid: constrain on the minimal mass of sub halos (e.g. through gravitational lensing).
- EDGES *could* have detected the first hint of DM-b interaction (a fraction of milli-charged DM) *Bowman et al, nature25792*
- Future: Smoking gun signals? Refine understanding of astrophysics to extract cosmology and particle physics?

Many tentative discoveries of DM nature

Unfortunately no coherent pictures emerge from these tentative detections...

The σ_8 tension

Figs. from Heymans++ 2007.15632

$$\sigma_8^2 \equiv \int_0^\infty dk \frac{k^2 P_L(k) W_R^2(k)}{2\pi^2}, \quad R = 8\text{Mpc}/h, \quad k \sim 0.1 - 1h/\text{Mpc}$$

- $\sim 2 - 3\sigma$ tension between **CFHTLenS/HSC/KiDS/DES** and *Planck*. (Potentially also Planck SZ clusters).

CFHTLenS MNRAS 2013, HSC PASJ 2019, DES PRD 2018, Salvati++ PoS 1901.05289

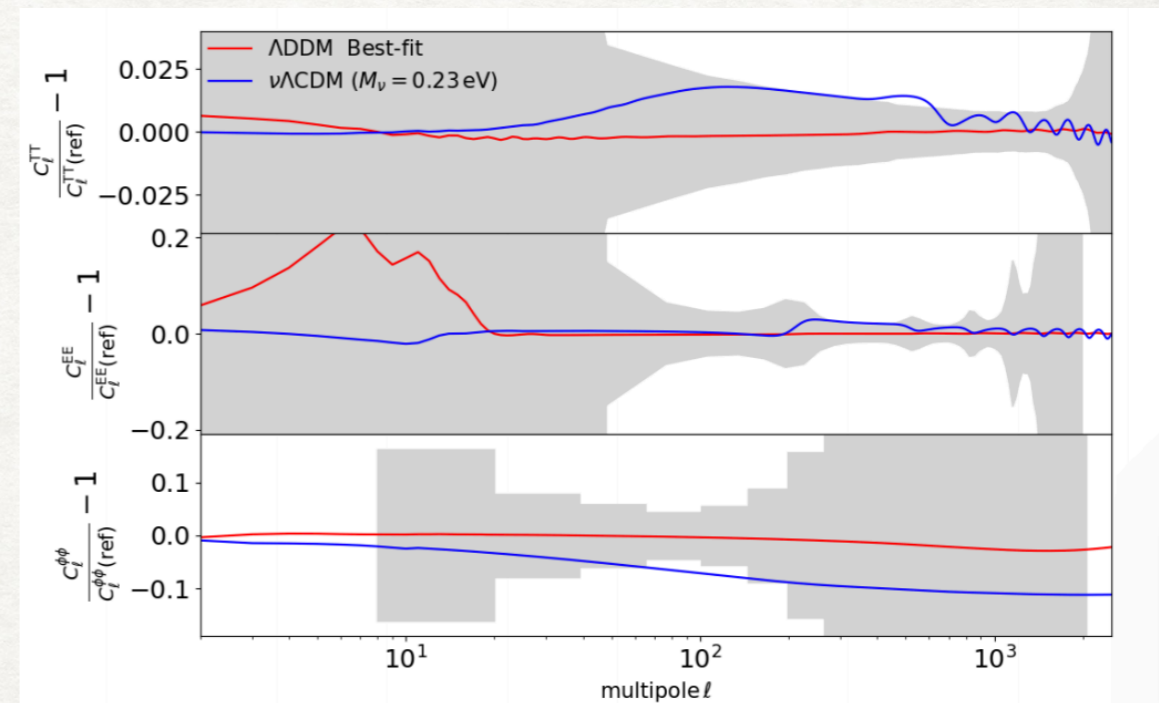

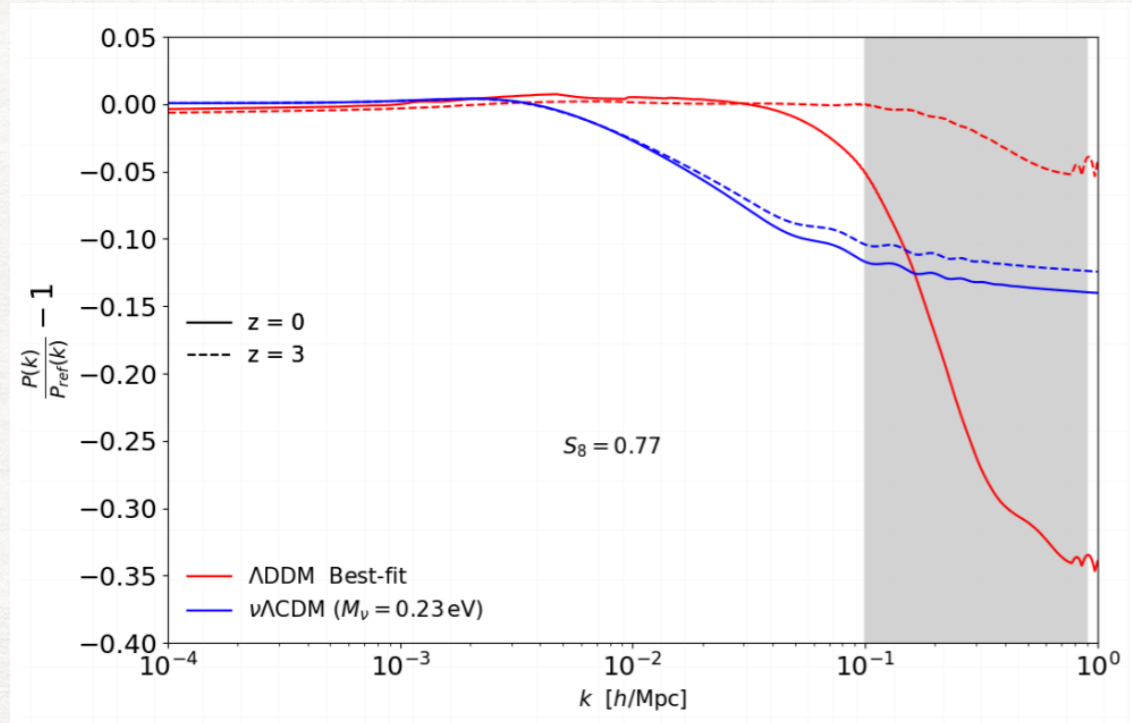

- To resolve the tension: reduce power at scales $k \sim 0.1 - 1 h/\text{Mpc}$. DM interactions or decays, fraction of fuzzy dark matter, hot dark matter.

See 'cosmology intertwined' white paper Di Valentino++ 2008.11285

Decaying Dark Matter and the S_8 tension

Abellan, Murgia++ 2008.09615, 2104.03329

See also Vattis++ 1903.06220

- DM with $\Gamma^{-1} \simeq 55(\epsilon/0.007)^{1.4}$ Gyrs with $\epsilon \simeq v_{\text{wdm}}/c$ can explain low S_8 .
- The warm daughter induces a power suppression similar to hot DM or non-zero m_ν but different time evolution.
- Future LSS measurements (EUCLID, VRO/LSST, DESI) will test the scenario.
- (Fraction of) HDM disfavored Das++ 2104.03329
- (Fraction of) Fuzzy DM seems to work Laguë++ 2104.07802

The Hubble tension

As of 2021, over 20 measurements and 800 papers!!

- Indirect: H_0 is a prediction from the Λ CDM model constrained with high- z data
- Direct: H_0 is measured at low- z in different ways
- Direct measurements are higher than predictions, not all are in strong tension.
- Average: tension between $4-6\sigma$
- Systematics? New Physics?

High Precision Measures of H_0

'Filtered version' w/ $\Delta H_0 \leq 3 \text{ km/s/Mpc}$

Barring systematic errors: no ‘concordance cosmology’ just yet

- What extension(s) could resolve these tensions? Many involve dark matter! None can fully resolve both tensions.

- H_0 : measure the **background** expansion rate. S_8 : measure the amplitude of **perturbations**.
- Background**: reduce the **sound horizon** at early times. **Perturbations**: reduce power at scales $k \sim 0.1 - 1$ h/Mpc.

Cosmology provides many powerful DM probes

- Many **gravitational clues** for the existence of Dark Matter on a **variety of scales**. Description “CDM” is purely parametric: **are we seeing signs of the nature of DM?**

- Broad phenomenology: complementarity of probes over a wide-variety of scales and times.
- CMB & BBN: strong constraints on electromagnetic energy injection
- Weak lensing and galaxy clustering: few-% precision. Some tension with LCDM?
- Lyman-alpha and dwarf galaxies: constrains m_{wdm} , m_a . Implications for ‘Small-scale crisis’?

- S_8 and H_0 tension have received a lot of attention: they could point to **Dark Matter interactions** (with Dark Energy, Dark radiation) or **decay**.
- Signatures of these models in the scale and time-dependence of $P(k,z)$!

- Theoretical challenge: extract “cosmological” & “particle physics” information from large surveys with large astrophysical uncertainties.

Future of Dark Matter searches in Cosmology

The future is bright: 21cm experiments, Simons Observatory, LSST, EUCLID...
If these tensions exist/are due to new physics in the dark sectors, we will know!

- Strength of the French community: Strong expertise in early universe / CMB / BBN. Important experimental involvement in Planck, Euclid, LSST. (INSU / IN2P3 / INP / CEA). Large astro / cosmology / particle physics communities.
- Weaknesses / Risks: DM is a “multi-messenger quest”. Need for a coordinate effort between particle physicists and astro/cosmologists. 21 cm cosmology will be huge in ~5 to 10 years.
