First reason

In order to better understand the role of the BMS group (first identified at null infinity) in the quantum theory, where physical states are usually defined on spacelike (Cauchy) hypersurfaces, it is important to unveil its action on spacelike (Cauchy) hypersurfaces, and thus, at spatial infinity.

(First reason, continued)

This has been done recently in four spacetime dimensions, through a reconsideration of the boundary conditions at spatial infinity.

New, consistent boundary conditions have been proposed, which are invariant under the full infinite-dimensional BMS group, providing a standard, non-trivial, canonical realization of the BMS symmetry.

Conclusions and
comments

(First reason, continued)

This has been done recently in four spacetime dimensions, through a reconsideration of the boundary conditions at spatial infinity.

New, consistent boundary conditions have been proposed, which are invariant under the full infinite-dimensional BMS group, providing a standard, non-trivial, canonical realization of the BMS symmetry.

This establishes also the important fact that the BMS symmetry is a symmetry of the theory and not just a symmetry at null infinity.

A central role in the analysis will be played by the gravitational action

which reads, in Hamiltonian form (Dirac, ADM),

$$S[g_{ij}, \pi^{ij}, N, N^i] = \int dt \left\{ \int d^d x \left(\pi^{ij} \partial_t g_{ij} - N^i \mathcal{H}_i^{\text{grav}} - N \mathcal{H}^{\text{grav}} \right) - B_\infty \right\}$$

where B_∞ is a boundary term at infinity and where

$$\mathcal{H}^{\text{grav}} = -\sqrt{g}R + \frac{1}{\sqrt{g}}(\pi^{ij}\pi_{ij} - \frac{1}{d-1}\pi^2) \approx 0, \quad \mathcal{H}_i^{\text{grav}} = -2\nabla_j \pi_i^j \approx 0.$$

The definition of the theory is completed by providing boundary conditions on the dynamical variables (definition of phase space), which are assumed to make the off-shell action finite.

To see the full BMS group, one must allow a “parity-twisted component” in the leading orders of the asymptotic metric and momenta.

One thus imposes

$$h_{ij} \equiv g_{ij} - \delta_{ij} = h_{ij}^{RT} + U_{ij}, \quad \pi^{ij} = \pi_{RT}^{ij} + V^{ij}$$

U_{ij} and V^{ij} are the parity-twisted contributions that take the form of a gauge transformation (rewritten in Hamiltonian form).

They are of the same order as the leading terms in h_{ij} and π^{ij} ($O(1/r)$ and $O(1/r^2)$) respectively but have the opposite parity.

To see the full BMS group, one must allow a “parity-twisted component” in the leading orders of the asymptotic metric and momenta.

One thus imposes

$$h_{ij} \equiv g_{ij} - \delta_{ij} = h_{ij}^{RT} + U_{ij}, \quad \pi^{ij} = \pi_{RT}^{ij} + V^{ij}$$

U_{ij} and V^{ij} are the parity-twisted contributions that take the form of a gauge transformation (rewritten in Hamiltonian form).

They are of the same order as the leading terms in h_{ij} and π^{ij} ($O(1/r)$ and $O(1/r^2)$) respectively but have the opposite parity.

For a canonical action of the Lorentz boosts, one imposes moreover that U_{ij} be parametrized by an $O(1)$ odd function of the angles $\overline{U}(\mathbf{n}^k) = O(1) = -U(-\mathbf{n}^k)$. Furthermore, V^{ij} is parametrized by an $O(1)$ even function of the angles $V(\mathbf{n}^k) = V(-\mathbf{n}^k)$.

Even though the ideas are identical, there are striking new features in 5 dimensions :

- The size of BMS_5 is bigger than expected. More precisely, the supertranslations depend on four functions of the angles.
- Supertranslation charges (including the energy) acquire non-linear contributions.
- The asymptotic symmetry generators form a non-linear algebra. In particular, the brackets of the boosts acquire cubic contributions.
- There are central charges among the different types of supertranslation generators.

Contrary to the familiar ADM expression for the energy in 4D,
the energy in 5D (with our relaxed boundary conditions) acquires
nonlinear contributions.

Explicitly,

$$E = 2 \oint_{S_\infty^3} d^3x \sqrt{\bar{\gamma}} \left[(1/2) \bar{h}_A^A + D_A \bar{\lambda}^A + 3 \bar{\lambda} - (1/8) \theta_{AB} \theta^{AB} \right]$$

where

$$g_{rr} = 1 + \frac{2\bar{\lambda}}{r^2} + \frac{h_{rr}^{(2)}}{r^3} + \mathcal{O}(r^{-4}), \quad (4.1)$$

$$g_{rA} = \frac{\bar{\lambda}_A}{r} + \frac{h_{rA}^{(2)}}{r^2} + \mathcal{O}(r^{-3}), \quad (4.2)$$

$$g_{AB} = r^2 \bar{g}_{AB} + r \theta_{AB} + \bar{h}_{AB} + \frac{h_{AB}^{(2)}}{r} + \mathcal{O}(r^{-2}). \quad (4.3)$$

As one increases the dimension, the analysis becomes more and more technically intricate

because the gap between the pure (improper) diffeomorphism piece in the expansion of the fields (generated by $O(1)$ vector fields) and the “Coulomb” piece widens by one power of $1/r$ as one increases the dimension by one.

Non linearities (of increasing order) then proliferate.

(Note that these non-linearities are not seen in current null infinity treatments which linearize the theory at infinity)

Preliminary analysis indicates that the size of the BMS group does not increase because the new terms in the diffeomorphism generators define proper gauge transformations.
