Nobel Prize 2020: Black holes' existence confirmed

Milky Way, Sagittarius A*

R. Penrose R. Genzel A. Ghez

Observations: BHs exist!

⇒ PBH is a plausible dark matter candidate, the only candidate known to exist in nature

Experimental constraints

A - Dark matter

B - candidate events from HSC, OGLE [1701.02151, 1901.07120]

C - interesting for GW, as well as transmuted NS -> BH population [1707.05849; 2008.12780]

D - seeds of supermassive black holes [astro-ph/0204486, arXiv:1202.3848, 2008.11184]

First candidate events [Takada et al., Kavli IPMU]

First candidate events from HSC and OGLE

[Niikura et al.. Nature Astron., arXiv:1701.02151, 1901.07120]

- Primordial fluctuations enhanced on small scales (inflation model)
- Yukawa interactions, "long-range" forces, radiative cooling => PBH
- Supersymmetry: Q-balls as building blocks of PBH
- Supersymmetry: Q-balls with long-range scalar forces
- Multiverse => PBHs

- Primordial fluctuations enhanced on small scales (inflation model)
- Yukawa interactions, "long-range" forces, radiative cooling => PBH
- Supersymmetry: Q-balls as building blocks of PBH
- Supersymmetry: Q-balls with long-range scalar forces
- Multiverse => PBHs

- Primordial fluctuations enhanced on small scales (inflation model)
- Yukawa interactions, "long-range" forces, radiative cooling => PBH
- Supersymmetry: Q-balls as building blocks of PBH
- Supersymmetry: Q-balls with long-range scalar forces
- Multiverse => PBHs

PBH formation mechanism: Yukawa "fifth force"

Yukawa interactions:

 $V(r) = \frac{y^2}{r} e^{-m_{\chi}r}$

$$y\chi ar{\psi}\psi$$

a heavy fermion interacting with a light scalar

A light scalar field \Rightarrow long-range attractive force, \Rightarrow instability similar to
gravitational instability,
only stronger

⇒ halos form even in radiation dominated universe [Amendola et al., 1711.09915; Savastano et al., 1906.05300; Domenech, Sasaki, 2104.05271] Same Yukawa coupling provides a source of **radiative cooling** by emission of gravitational radiation ⇒ halos collapse to black holes [Flores, AK, 2008.12456, PRL 126 (2021) 041101; 2008.12456]

Growth of structures due to Yukawa force: N-body simulations

Inman, PRELIMINARY Domenech, Inman, Sasaki, AK work in progress

Rapid growth of structures... plus radiative cooling!

Same Yukawa fields allow particles moving with acceleration emit scalar waves

Flores, AK, Phys.Rev.Lett. 126 (2021) 4, 041101; 2008.12456

\Rightarrow radiative cooling and collapse to black holes

PBH DM abundance natural for m_{ψ} ~1-100 GeV

Asymmetric dark matter models: Asymmetry in the dark sector = baryon asymmetry

In our case, all these particles end up in black holes:

$$f_{\rm PBH} = \frac{\Omega_{\rm PBH}}{\Omega_{\rm DM}} = 0.2 \frac{m_{\psi}}{m_p} \frac{\eta_{\psi}}{\eta_{\rm B}} = \left(\frac{m_{\psi}}{5 \,\text{GeV}}\right) \left(\frac{\eta_{\psi}}{10^{-10}}\right)$$

Similar to asymmetric dark matter [Petraki]

[Flores, AK, 2008.12456, PRL 126 (2021) 041101]

Natural explanation for the ratio

(dark matter density) / (ordinary matter density) for ~1-100 GeV masses

- Primordial fluctuations enhanced on small scales (modify inflation)
- Yukawa interactions, "long-range" forces, radiative cooling => PBH
- Supersymmetry: Q-balls as building blocks of PBH
- Supersymmetry: Q-balls with long-range scalar forces
- Multiverse => PBHs

Scalar fields in de Sitter space (used by Affleck-Dine)

A scalar with a small mass develops a VEV

[Chernikov, Tagirov; Starobinsky, Zeldovich; Bunch, Davies; Linde; Affleck, Dine; Starobinsky, Yokoyama]

Scalar fields in de Sitter space (used by Affleck-Dine)

A scalar with a small mass develops a VEV

[Chernikov, Tagirov; Starobinsky, Zeldovich; Bunch, Davies; Linde; Affleck, Dine; Starobinsky, Yokoyama]

Scalar fields: an instability (Q-balls)

Gravitational instability can occurs due to the attractive force of gravity.

Similar instability can occur due to scalar self-interaction which is **attractive**:

$$U(\phi) \supset \lambda_3 \phi^3$$
 or $\lambda_{\chi \phi \phi} \chi \phi^{\dagger} \phi$

[AK, Shaposhnikov, hep-ph/9709492]

Scalar fields: an instability (Q-balls)

homogeneous solution
$$\varphi(x,t) = \varphi(t) \equiv R(t)e^{i\Omega(t)}$$

 $\delta R, \delta \Omega \propto e^{S(t)-i\vec{k}\vec{x}}$
 $\ddot{\delta\Omega} + 3H(\dot{\delta\Omega}) - \frac{1}{a^2(t)}\Delta(\delta\Omega) + \frac{2\dot{R}}{R}(\dot{\delta\Omega}) + \frac{2\dot{\Omega}}{R}(\dot{\delta R}) - \frac{2\dot{R}\dot{\Omega}}{R^2}\delta R = 0,$

$$\ddot{\delta R} + 3H(\dot{\delta R}) - \frac{1}{a^2(t)}\Delta(\delta R) - 2R\dot{\Omega}(\dot{\delta \Omega}) + U''\delta R - \dot{\Omega}^2\delta R = 0.$$

1

$$(\dot{\Omega}^2 - U''(R)) > 0 \Rightarrow \text{growing modes: } 0 < \mathbf{k} < \mathbf{k}_{\mathrm{max}} < \mathbf{k}_{$$

$$k_{max}(t) = a(t)\sqrt{\dot{\Omega}^2 - U''(R)}$$

Also of interest: oscillons

$$M_{\rm hor} \sim r_f^{-1} \left(\frac{M_{\rm Planck}^3}{M_{\rm SUSY}^2}\right) \sim 10^{23} {\rm g} \left(\frac{100 {\rm TeV}}{M_{\rm SUSY}}\right)^2$$

7 1

$$M_{\rm PBH} \sim r_f^{-1} \times 10^{22} {\rm g} \left(\frac{100 {\rm TeV}}{M_{\rm SUSY}}\right)^2$$

Cotner, AK, Phys.Rev.Lett. 119 (2017) 031103 Cotner, AK, Sasaki, Takhistov, JCAP 1910 (2019) 077

- Primordial fluctuations enhanced on small scales (modify inflation)
- Yukawa interactions, "long-range" forces, radiative cooling => PBH
- Supersymmetry: Q-balls as building blocks of PBH
- Supersymmetry: Q-balls with long-range scalar forces
- Multiverse => PBHs

Yet another way to get PBHs from SUSY: long-range forces

A SUSY flat direction φ can couple to another SUSY scalar, χ , which can mediate long-range forces between SUSY Q-balls, leading to Yukawa long-range potential

- Primordial fluctuations enhanced on small scales (modify inflation)
 Yukawa interactions, "long-range" forces, radiative cooling => PBH
- Supersymmetry: Q-balls as building blocks of PBH
- Supersymmetry: Q-balls with long-range scalar forces
- Multiverse => PBHs

And yet another mechanism: inflationary multiverse

Tunneling events lead to nucleation of baby universes, which appear to outside observer as black holes.

PBH and neutron stars

- Neutron stars can capture PBH, which consume and destroy them from the inside.
- Capture probability high enough in DM rich environments, e.g. Galactic Center
- Missing pulsar problem...
 [e.g. Dexter, O'Leary, arXiv:1310.7022]
- What happens if NSs really are systematically destroyed by PBH?

Neutron star destruction by black holes ⇒r-process nucleosynthesis, 511 keV, FRB

[Fuller, AK, Takhistov, Phys.Rev.Lett. 119 (2017) 061101]

Fast-spinning millisecond pulsar.

Image: NASA/Dana Berry

MSP spun up by an accreting PBH

r-process material

- MSP with a BH inside, spinning near mass shedding limit: elongated spheroid
- Rigid rotator: viscosity sufficient even without magnetic fields [Kouvaris, Tinyakov]; more so if magnetic field flux tubes are considered
- Accretion leads to a decrease in the radius, increase in the angular velocity (by angular momentum conservation)
- Equatorial regions gain speed in excess of escape velocity: ejection of cold neutron matter

[Fuller, AK, Takhistov, Phys. Rev. Lett. 119 (2017) 061101] also, Viewpoint by H.-T. Janka

r-process nucleosynthesis: site unknown

- s-process cannot produce peaks of heavy elements
- Observations well described by r-process
- Neutron rich environment
 needed
 - Site? SNe? NS-NS collisions?..

Image: Los Alamos, Nuclear Data Group

r-process nucleosynthesis: site unknown

- **SN**? Problematic: neutrinos
- **NS mergers**? Can account for all r-process?

Image: Los Alamos, Nuclear Data Group

NS-NS might not be not enough...

THE ASTROPHYSICAL JOURNAL, 900:179 (33pp), 2020 September 10

<u>Scientists dazed and confused by extraordinary amount of Gold in the</u>

<u>UNIVERSE</u>

Kobayashi,

There's too much gold in the universe. No one knows where it came from.

By Rafi Letzter - Staff Writer 12 days ago

Something is showering gold across the universe. But no one knows what it is.

Figure 39. The time evolution (in Gyr) of the origin of elements in the periodic table: Big Bang nucleosynthesis (black), AGB stars (green), core-collapse supernovae including SNe II, HNe, ECSNe, and MRSNe (blue), SNe Ia (red), and NSMs (magenta). The amounts returned via stellar mass loss are also included for AGB stars and core-collapse supernovae depending on the progenitor mass. The dotted lines indicate the observed solar values.

[Kobayashi et al., ApJ 900:179, 2020]

r-process material: observations

Milky Way (total): M~10⁴ M_o

Ultra Faint Dwarfs (UFD): most of UFDs show no enhancement of r-process abundance.

However, **Reticulum II** shows an enhancement by factor **10²-10³**!

"Rare event" consistent with the UFD data: one in ten shows r-process material [Ji, Frebel et al. Nature, 2016]

NS disruptions by PBHs

- Centrifugal ejection of cold neutron-rich material (~0.1 M_☉) MW: M~10⁴ M_☉ ✓
- UFD: a rare event, only one in ten UFDs could host it in 10 Gyr ✔
- Globular clusters: low/average DM density, but high density of millisecond pulsars. Rates OK. ✓

[Fuller, AK, Takhistov, PRL 119 (2017) 061101] also, a *Viewpoint* PRL article by Hans-Thomas Janka

NS disruptions by PBHs

- Weak/different GW signal
- No significant neutrino emission
- Fast Radio Bursts
- Kilonova event without a GW counterpart, but with a possible coincident FRB (LSST, ZTF,...)
- 511 keV line

[Fuller, AK, Takhistov, Phys. Rev. Lett. 119 (2017) 061101]

511-keV line in Galactic Center

Origin of positrons unknown. Need to produce 10⁵⁰ positrons per year. Positrons must be produced with energies below 3 MeV to annihilate at rest. [Beacom,Yuksel '08]

Cold, neutron-rich material ejected in PBH-NS events is heated by β -decay and fission to T~0.1 MeV

 \rightarrow generate 10⁵⁰ e⁺/yr for the rates needed to explain r-process nucleosynthesis. Positrons are non-relativistic.

ESA/Bouchet et al.

$$\Gamma(e^+e^- \to \gamma\gamma) \sim 10^{50} \mathrm{yr}^{-1}$$

Fuller, AK, Takhistov, Phys. Rev. Lett. 119 (2017) 061101

Fast Radio Bursts (FRB)

Origin unknown. One repeater, others: non-repeaters. τ ~ ms.

PBH - NS events: final stages dynamical time scale τ ~ ms. NS magnetic field energy available for release: ~ 10^{41} erg Massive rearrangement of magnetic fields at the end of the NS life, on the time scale ~ms produces an FRB. **Consistent with observed FRB fluence.**

GW detectors can discover small PBH...

PBH + NS ↓ BH of 1-2 M_☉

[Takhistov et al., 1704.01129, 1707.05849; 2008.12780]

...if it detects mergers of **1-2 M_O black holes** (not expected from evolution of stars)

Conclusion

- Simple, generic formation scenarios in the early universe: PBH from scalar forces, PBH from a scalar field fragmentation, PBH from vacuum bubbles...
- PBH with masses $10^{-16} 10^{-10} M_{\odot}$, motivated by 1-100 TeV scale **supersymmetry**, can make up 100% (or less) of dark matter. **PBH is a generic dark matter candidate in SUSY**
- PBH from ~ 1-100 GeV scale particles can naturally explain DM abundance
- Microlensing (HSC) can detect the tail of DM mass function.
- PBH can contribute to r-process nucleosynthesis
- Signatures of PBH:
 - Kilonova without a GW counterpart, or with a weak/unusual GW signature
 - \circ $\,$ An unexpected population of 1-2 $\rm M_{\odot}$ black holes (GW)
 - Galactic positrons, FRB, etc.
