The Belle II Experiment

- ▶ International collaboration based in Japan.
- ▶ Data taking since **2019**.
- ▶ Comprised of asymmetric e^+e^- **SuperKEKB** collider (10.58 GeV) and **Belle II** detector.
- ▶ Main target : discovery of **BSM** physics.

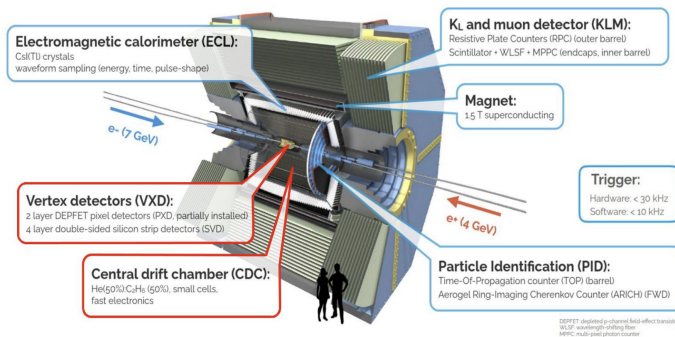

The Belle II Experiment

- ▶ Data taking since **2019**.
- ▶ Current Luminosity:
 - **Highest instantaneous luminosity** in the world $2.4 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$
 - Already collected 219 fb^{-1}
- ▶ Luminosity target:
 - Peak luminosity $\sim 6 \times 10^{35} \text{ cm}^{-2} \text{ s}^{-1}$
 - Collect 50 ab^{-1}
- ▶ Thanks to nano-beam scheme, high current

SVD roles:

- ▶ Extrapolate tracks to PXD
 - essential for reconstruction of decay vertices
 - PXD region of interest for data reduction
- ▶ Stand-alone tracking for low momentum tracks
- ▶ PID with dE/dx

Silicon Vertex Detector

SVD:

4 layers (SVD) of double-sided Si strip sensors (DSSD):

Side u/P along $r\phi$ -direction

Side v/N along z-direction

Double Sided Strip Detector DSSD

3 shapes of DSSD used in ladders

Digital estimated resolution counting floating strips:

$$\sigma_{\text{digit}} = \frac{\text{Pitch}}{2\sqrt{12}} \quad (1)$$

Layer (Side)	3 (u/P)	456 (u/P)	3 (v/N)	456 (v/N)
Strip Pitch (μm)	50	75	160	240
Digital Resolution (μm)	7	10	23	34

Spatial Resolution

Motivations

- ▶ Excellent Spatial resolution is mandatory for SVD reconstruction, crucial input for tracking:
 - Improve quality of reconstructed tracks and vertices
 - Correctly propagate uncertainty on hit's position to track parameters

Spatial Resolution

Ingredients

True Position	x	
Cluster Position	m	→ Center of Gravity
Unbiased Track Position	t	→ Track fitting
Track position error	σ_t	

Residuals:

Residual	$R = m - t$
Track Residual	$\varepsilon_t = t - x$
True Residual	$\varepsilon_m = m - x$

Spatial Resolution σ_{cl} :

$$\sigma_{cl}^2 := \text{Var}[\varepsilon_m] \quad (2)$$

$$:= E[(m - x)^2] - E[(m - x)]^2 \quad (3)$$

Nonetheless the true position x is only available in Monte-Carlo samples.

 - 2.1 Motivations
 - 2.2 Ingredients for resolution measurements
- 3 **CI Pos Resolution Measurements**
 - 3.1 Event by Event Method
 - 3.2 Global Method
 - 3.3 Overlapping Method
- 4 Unfolding

Event by event method:

Subtract in quadrature the effect of the error on track extrapolation on residual:

$$\sigma_{cl}^2 = \langle R^2 - \sigma_t^2 \rangle_{trunc} \quad (4)$$

- Discrepancy between true and measured resolution on simulation
- Solved by optimising the quantile truncation on $R^2 - \sigma_t^2$ following:

$$FOM = \frac{(\sigma_{true} - \sigma_{cl})^2}{(\Delta\sigma_{cl})^2} \quad (5)$$

Event by Event Method

Data and Simulation results

Event by Event Method

Data results

13

- ▶ v/N Side reaches the digital resolution for perpendicular tracks (low cluster size). Smaller resolution for higher angle and cluster size.
- ▶ Maybe still some room for improvements on u/P side

Global Method:

Based on Mean Absolute Deviation (MAD) as best estimator : no optimization on MC needed.

$$\sigma_{cl}^2 = \langle R^2 - \sigma_t^2 \rangle \simeq \text{mad}(R)^2 - \text{median}(\sigma_t)^2 - \text{mad}(\sigma_t)^2$$

- ▶ $\text{mad}(y) = 1.4826 \times \text{median}(|y - \text{median}(y)|)$
- ▶ mad and median more robust against outliers than standard deviation and mean.

- Results in agreement with event by event method: data/MC agreement, angular distribution..
- The Global Method allows to estimate the spatial resolution in a robust way.
- Small discrepancies between data and simulation.

Overlapping Method:

- ▶ Select tracks in fiducial area with two hits on the same layer and on consecutive ladders
- ▶ Compare residuals computed for the pair of overlapping ladder, double residuals:

$$\Delta R = R_{int} - R_{ext} \quad (6)$$

- ▶ Apply geometrical correction due to non-parallel sensors
- ▶ Resolution is the σ_{68} width of a Student-T distribution fit

- ▶ Marginally sensitive to Coulomb scattering
- ▶ Decouple contribution of tracking uncertainty
→ assuming the error on the track extrapolation cancel out in the double difference!
- ▶ Most critical side for resolutions in u/P direction, due to the reduced overlapping region: limited angle range and statistics.

Overlaps

Data results

17

- ▶ Outermost v/N side layers are in agreement with expected digital resolution
- ▶ Measured resolutions with overlaps approach are larger than expected/other methods, even on simulation

- 1 The Belle II Experiment
- 2 Spatial Resolution
 - 2.1 Motivations
 - 2.2 Ingredients for resolution measurements
- 3 Cl Pos Resolution Measurements
 - 3.1 Event by Event Method
 - 3.2 Global Method
 - 3.3 Overlapping Method
- 4 **Unfolding**

Charge coupling between strips

- ▶ A **signal** is injected on a given strip, the waveform of the **adjacent channel** is also checked.
- ▶ A small signal is observed on the adjacent channel with a lower time ($\simeq 27ns$)

Expected effect on strip charges:

$$charge_{obs}(a) = charge_{true}(a) + c \times charge_{true}(b)$$

Strip charge is used to compute position : impact on resolution !

Correction by unfolding

The observed charges follow:

$$a_i = (1 - 2c)A_i + c(A_{i-1} + A_{i+1})$$

From the observations on data, $c = 0.1$

Correction by unfolding

21

To correct this effect, we link the *observed* charges to the *true* charges :

$$\begin{pmatrix} 1 - 2c & c & 0 & 0 \\ c & 1 - 2c & c & 0 \\ 0 & c & 1 - 2c & c \\ 0 & 0 & c & 1 - 2c \end{pmatrix} \begin{pmatrix} A_1 \\ A_2 \\ A_3 \\ A_4 \end{pmatrix} = \begin{pmatrix} a_1 \\ a_2 \\ a_3 \\ a_4 \end{pmatrix}$$

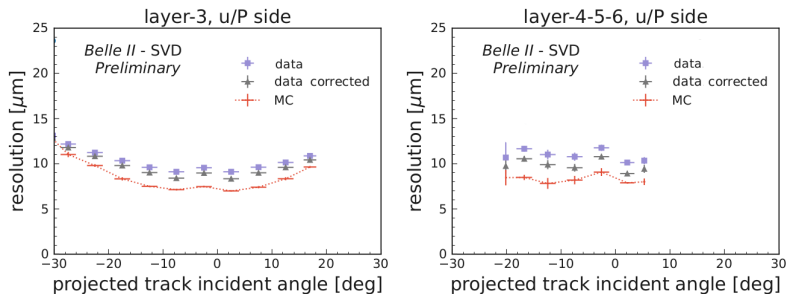

Then **unfold** the charges by inversion :

$$\begin{pmatrix} A_1 \\ A_2 \\ A_3 \\ A_4 \end{pmatrix} = M^{-1} \begin{pmatrix} a_1 \\ a_2 \\ a_3 \\ a_4 \end{pmatrix}$$

The observed charges follow:

$$a_i = (1 - 2c)A_i + c(A_{i-1} + A_{i+1})$$

From the observations on data, $c = 0.1$

- This correction only yields improvements for u/P side.
- The unfolding method improves data/MC agreement : allows to breach $\simeq 20 - 30$ % of the gap.
- Correction implemented in the Belle II analysis software

- Different method developed to estimate spatial resolution :

Event By Event	Global	Overlaps
Good estimation of spatial resolution	Good estimation of spatial resolution	Marginally sensitive to Coulomb scattering
Data/MC agreement	No optimization needed	
Optimization on MC needed	Small Data/MC discrepancies	Estimated resolution higher than expected

- Development of the unfolding method: correction of data that improves the spatial resolution measured on u/P side.

Thanks for your attention

Backups

Cluster reconstruction

- For each cluster, computation of:
 - Charge S_{cl}
 - Position x_{cl}
 - Time t_{cl}
- For a cluster made of n strips
- $S_{cl} = \sum S_i$
- $x_{cl} = \sum x_i S_i / \sum S_i$ (Center of gravity)
- $t_{cl} = \sum t_i S_i / \sum S_i$ (Center of gravity)

Estimation of cluster position resolution

- We define the quantity σ_{cl}^2 as : $\sigma_{cl}^2 = \langle res^2 - \sigma_l^2 \rangle = \langle res^2 \rangle - \langle \sigma_l^2 \rangle$
 $= \text{mean}(res)^2 - \text{mean}(\sigma_l)^2 - \text{std.dev}(\sigma_l)^2$
- Since the distributions are not perfectly gaussian use instead :
 - $\text{mean}(x) \approx \text{median}(x)$
 - $\text{Std.dev}(x) \approx \text{mad}(x) \equiv 1.4826 * \text{median}(|x - \text{median}(x)|)$
- Then $\sigma_{cl}^2 = \text{mad}(res)^2 - \text{median}(\sigma_l)^2 - \text{mad}(\sigma_l)^2$

Errors estimation in Event by event method:

1. Statistical uncertainties

Taking variance of resolution squared as variance of sample mean

$$\Delta\sigma_{Cl} = \frac{1}{2\sigma_{Cl}} \sqrt{\frac{\langle (R^2 - \delta_t^2)^2 \rangle - \sigma_{Cl}^4}{N}}$$

2. Systematic uncertainties

Adding in quadrature:

- Variation in resolution measurement with and without selection on residual
- Variation in resolution measurement with quantile truncation at $\mp 0.2\%$ (step) between optimal quantile

Errors estimation in Global method:

1. Statistical uncertainties

- For median $\frac{mad}{\sqrt{N}}$
- For mad $\sqrt{2} \frac{mad}{\sqrt{N-1}}$

2. Systematic uncertainties:

Difference with another robust estimator that should give the same result for Gaussian distributions

- For median $|median - midhinge|$
(average of the first and third quartiles)
- For mad $|mad - \sigma_{68}|$

Method for estimate resolution with overlapping:

1. Apply geometrical correction factor on double residuals
2. Fit **DeltaRes** with a student's t-distribution:

$$T(X, \nu, \mu, \sigma) = \frac{\exp\left(\Gamma\left(\frac{\nu+1}{2}\right) - \Gamma\left(\frac{\nu}{2}\right)\right)}{\sigma \sqrt{\pi \nu}} \left(1 + \frac{(X - \mu)^2}{\sigma^2 \nu}\right)^{-\frac{\nu+1}{2}}$$

normalisation parameter N

number of degree of freedom ν

mean μ

variance σ^2

3. The resolution is the σ_{68} of the fitted student's t-model T

$$\sigma_{cl} = \sigma_{68}(T(X, \nu, \mu, \sigma)) \\ = \frac{\chi_{84}(T(X, \nu, \mu, \sigma)) - \chi_{16}(T(X, \nu, \mu, \sigma))}{2}$$

True Resolution in Monte-Carlo:

$$\sigma_{68}(m - x)$$

Cluster position m

True position x

Method for estimate resolution uncertainties:

1. Vary fitted parameters (N, μ , ν , σ) within the fit uncertainties (\pm Fit errors)
2. Compute student's T-model with new parameters
3. Taking σ_{68} resolution of this new model
4. Take as resolution uncertainty for each layer half the maximal variation of the recomputed σ_{68} :

$$\frac{\max(\sigma_{68}) - \min(\sigma_{68})}{2}$$

Backups

Details on Overlaps method

30

Geometrical correction:

Project parallel to the tracks, the external residual on internal ladder.

u/P Side:

$$\Delta R = \frac{R_{int} - R_{ext} * C}{\sqrt{1 + C^2}}$$

with $C = \frac{\cos a_{ext}}{\cos a_{int}}$

v/N Side:

$$\Delta R = \frac{R_{int} - (R_{ext} + \sin(i) \tan(a_{ext}) R_{ext}^{u/P})}{\sqrt{2}}$$

Cluster unfolding method – estimation of best correction factor

- The resolution is computed for each type of sensor for different values of c ranging from **0** to **0.2**
- The unfolding method does not improve the resolution on V-side sensors
- However, **U-side** sensors do benefit from the method, with an optimal gain with $c = 0.1$ for all type of sensors
