

# Cosmic Neutrinos in Louvain-la-Neuve

francis halzen

ICECUBE

- ANTARES, Baikal GVD, IceCube
- the diffuse high-energy neutrino flux
- observation of the first sources
- multimessenger astronomy: plan B

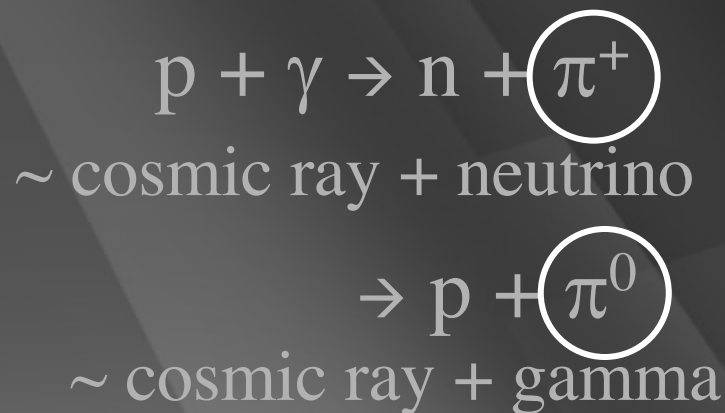

# $\nu$ and $\gamma$ beams : heaven and earth

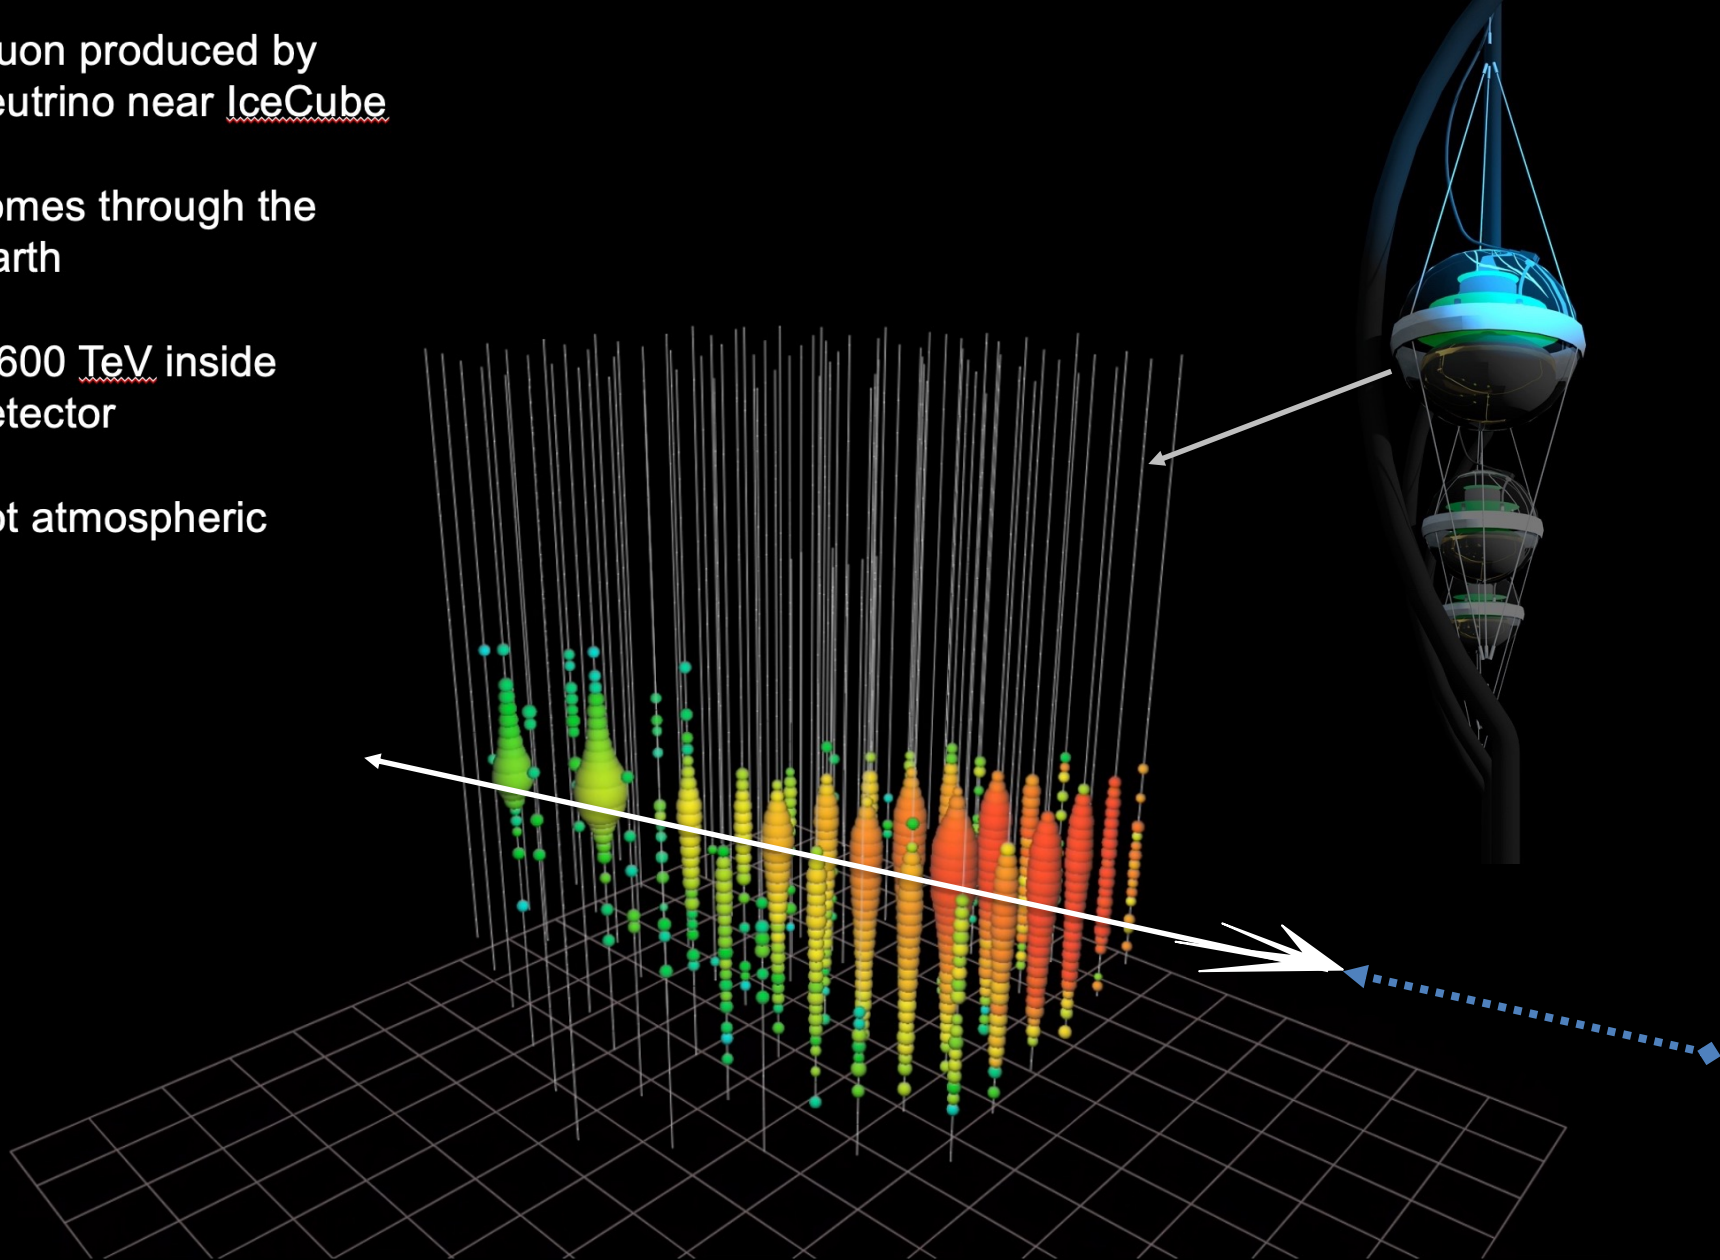

accelerator is powered by large gravitational energy

→ **supermassive black hole**

→ **nearby radiation or hydrogen, or...**

- muon produced by neutrino near IceCube
- comes through the Earth
- 2,600 TeV inside detector
- not atmospheric

- muon produced by neutrino near IceCube
- comes through the Earth
- 2,600 TeV inside detector
- not atmospheric
- angular resolution: astronomy

neutrinos interacting  
inside the detector

muon neutrinos  
filtered by the Earth

date: **June 11, 2014**  
most probable energy: **9 PeV**  
topology: **track**

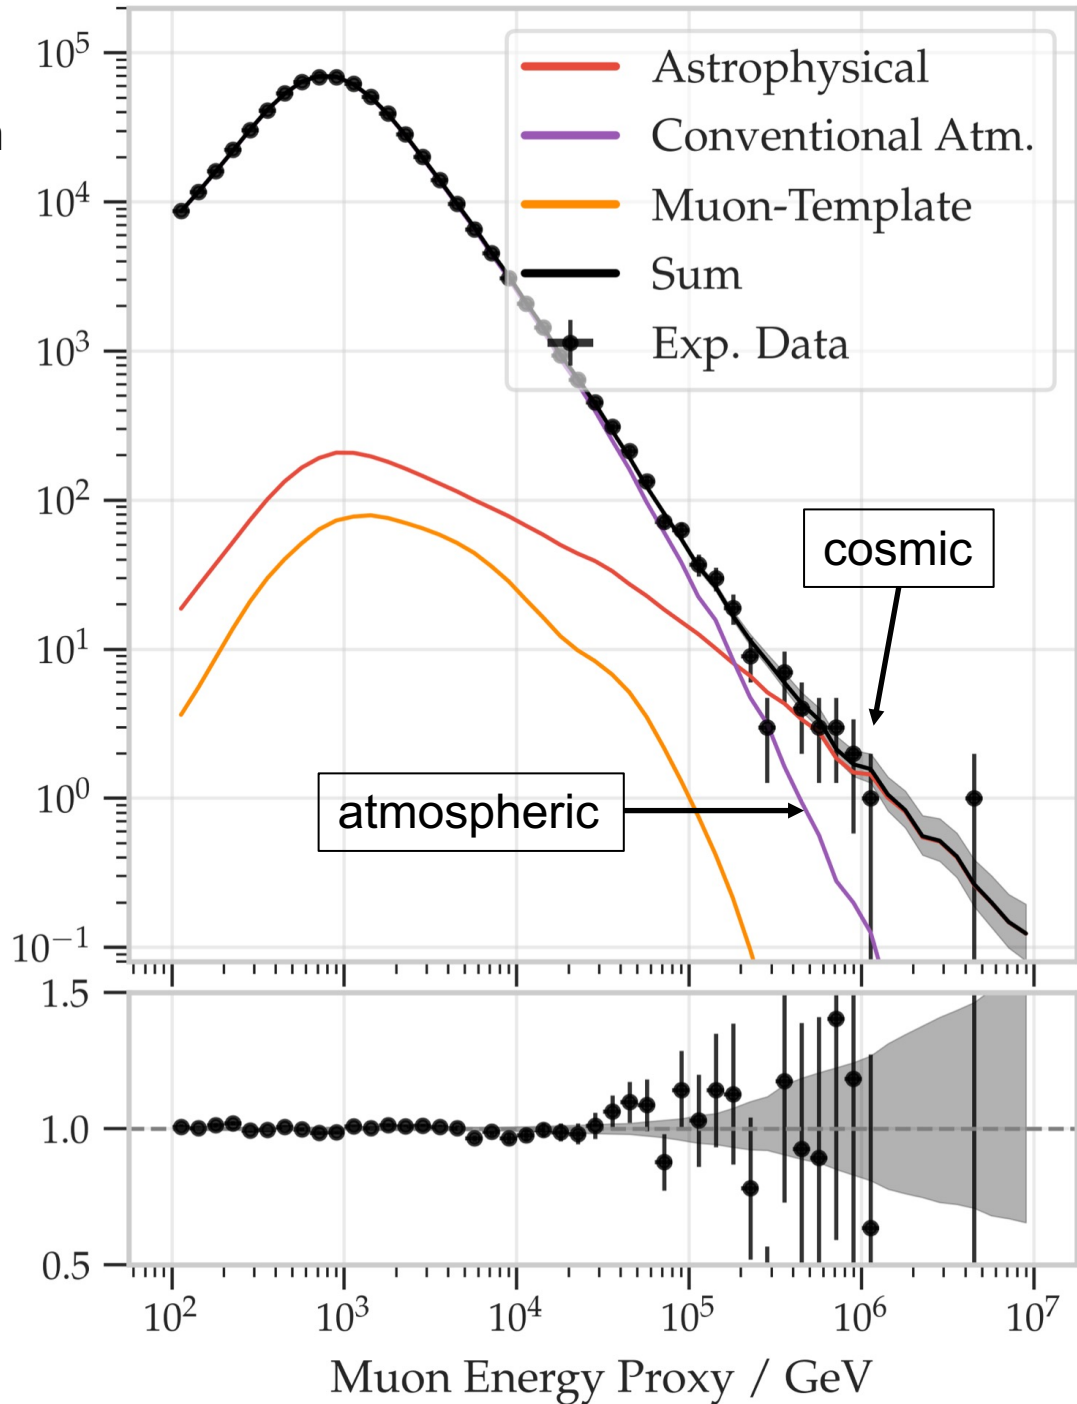

superior total energy  
measurement  
to 10%, all flavors, all sky

astronomy: superior  
angular resolution  
superior ( $0.3^\circ$ )

Number of Events per Bin

muon neutrino flux  
filtered by the Earth:  
atmospheric vs  
cosmic

# electron and tau neutrinos (showers)

$$E^2 dN/dE \sim E^{-2.5}$$

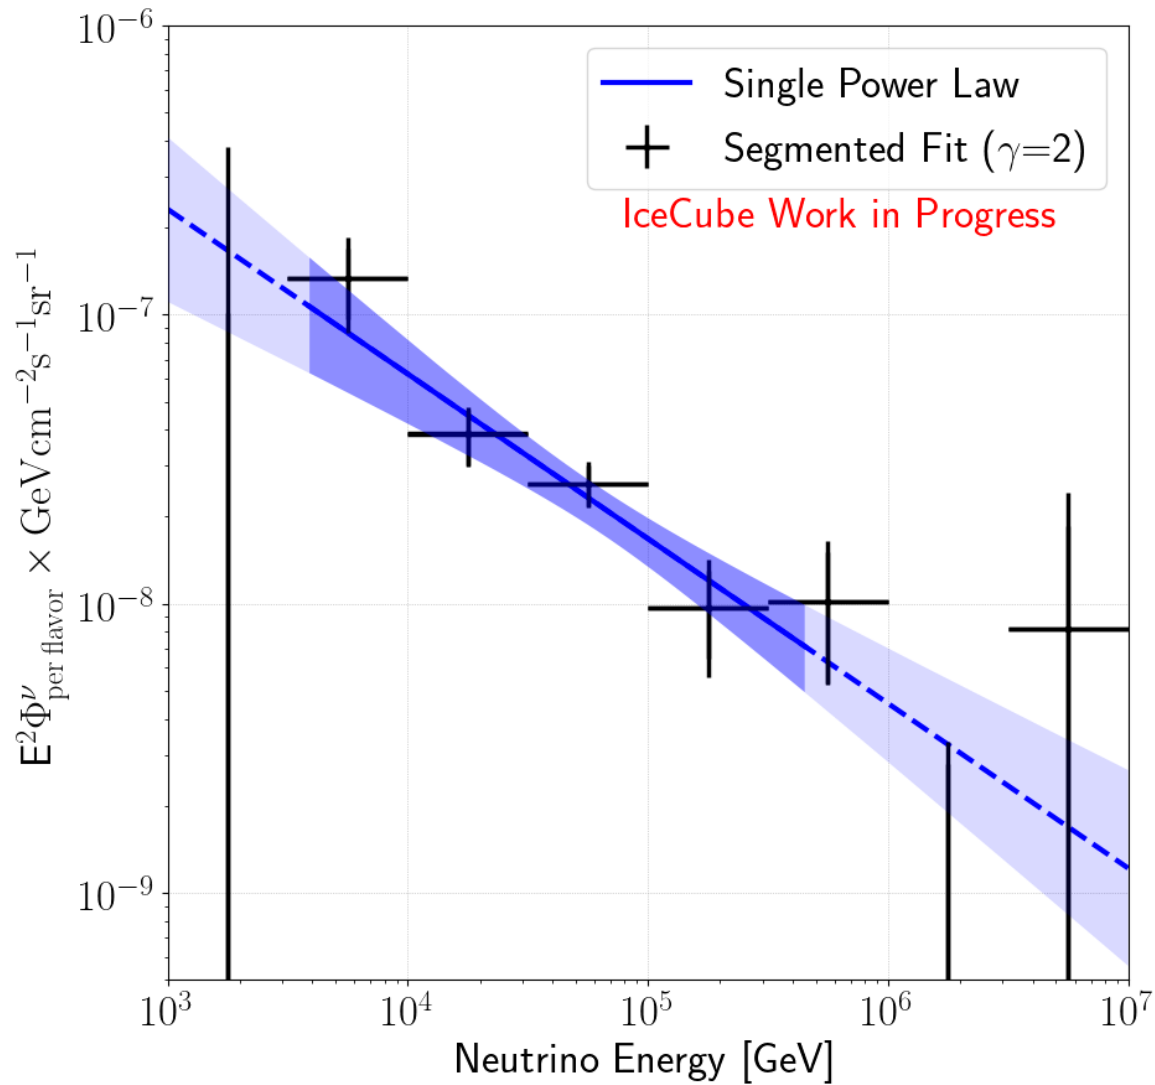

# muon neutrinos through Earth (tracks)

# update: multi-year cascade ( $\nu_e + \nu_\tau$ ) analysis

# update: multi-year starting $\nu_\mu$ track analysis

## All-sky search for HE cascades [arXiv:2211.09447](https://arxiv.org/abs/2211.09447)

Additional selection requirements:

( $N_{\text{hit}_\mu} = 0, E_{\text{rec}} \geq 70 \text{ TeV}$ ) or

( $N_{\text{hit}_\mu} = 1, E_{\text{rec}} \geq 100 \text{ TeV}$ )

$N_{\text{hit}_\mu}$  is number of hits in time interval where hits from muons are expected

Expected:

7.4 events from atm. muons

0.8 events from atm. neutrinos

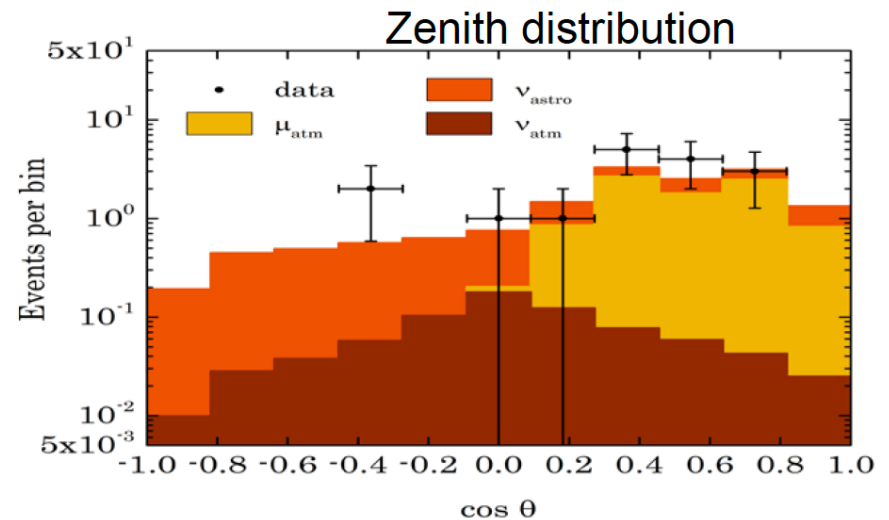

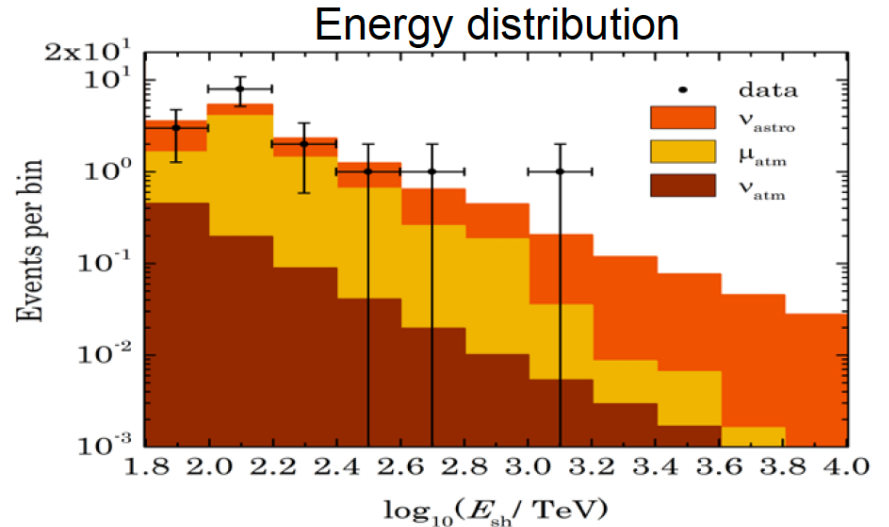

5.8 events for Baikal-GVD best fit

$E^{-2.58}$  astrophysical flux

Found in real data: 16 events

Probability for the background-only hypothesis (stat.+sys.)

**P-value = 0.026 (2.22  $\sigma$ )**

# Search for upward moving events [arXiv:2211.09447](https://arxiv.org/abs/2211.09447)

Additional selection requirements:

$$E > 15 \text{ TeV} \ \& \ N_{\text{hit}} > 11 \ \& \ \cos\theta < -0.25$$

Expected:

0.5 events from atm. muons

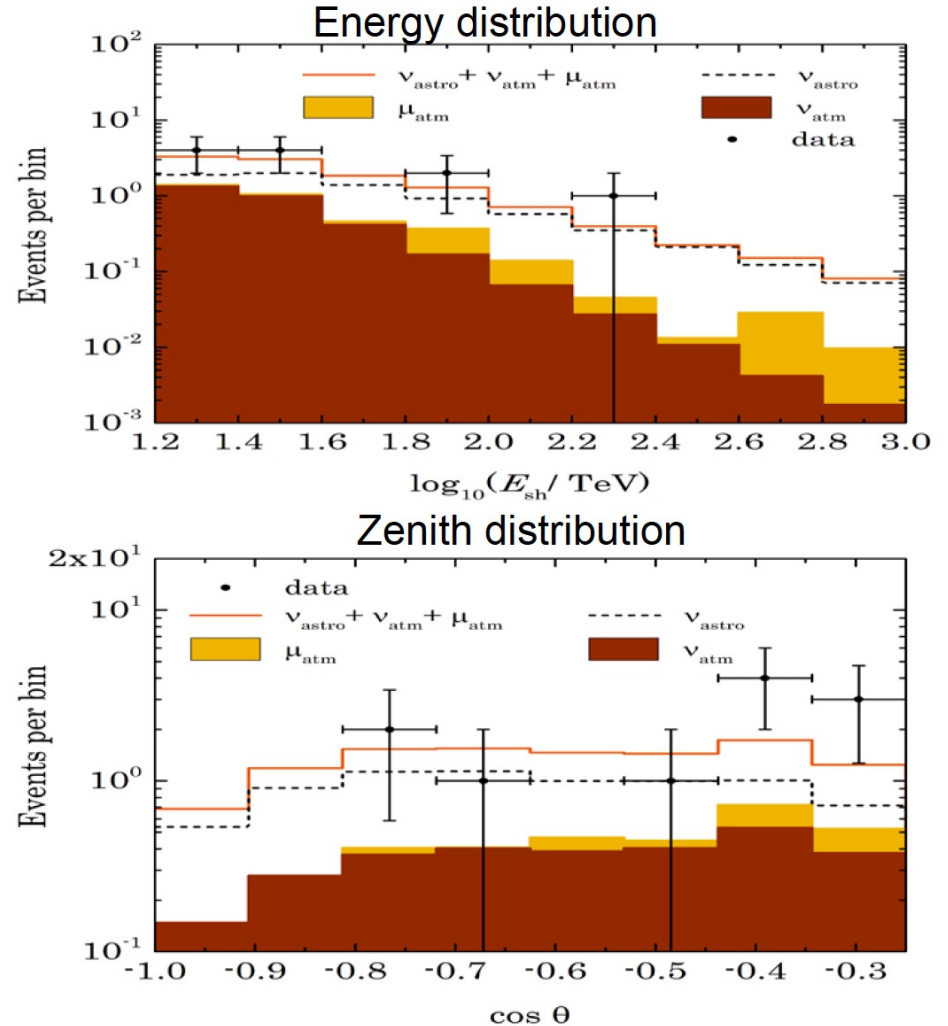

2.7 events from atm. neutrinos

6.3 events for Baikal-GVD best fit  $E^{-2.58}$   
astrophysical flux

Found in data: 11 events

Probability for the background-only hypothesis (stat.+sys.)

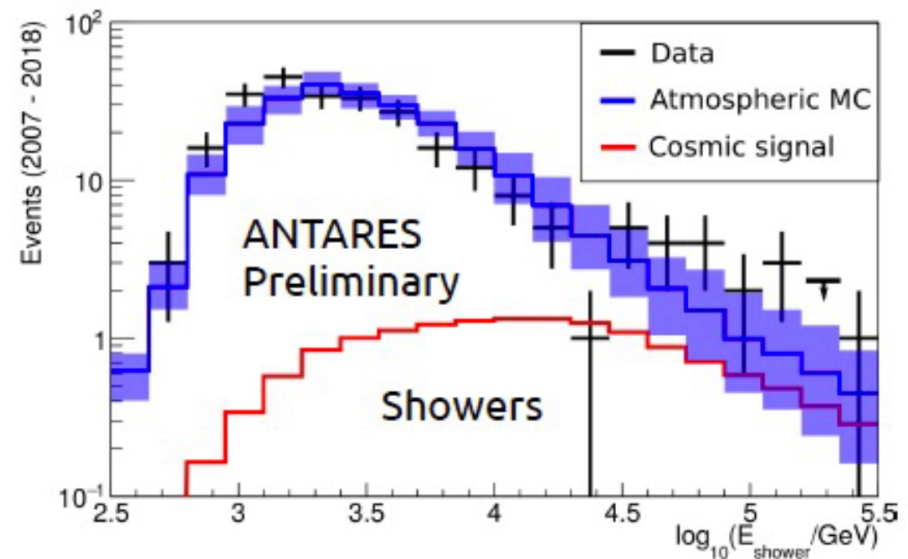

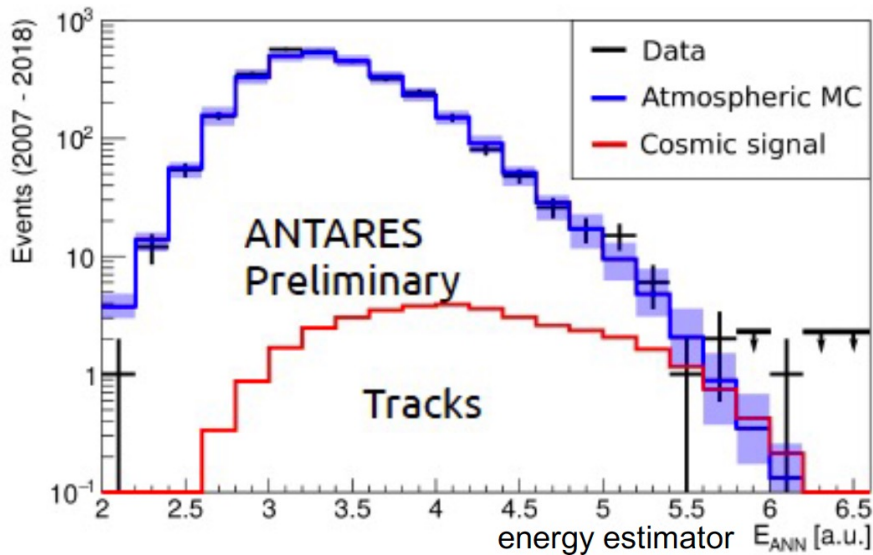

**P-value = 0.0024 ( $3.05\sigma$ )**

# ANTARES

Updated data sample @ ICRC2019: 2007-2015 (2450 days) → 2007-2018 (3330 days)  
All-sky / All-flavor neutrino search

- Selection cuts optimized with MRF procedure (assumed spectral index  $\Gamma = 2.5$ )
- Look for excess above a given  $E_{\text{th}}$
- Combine track & shower samples

Data: 50 events (27 tracks + 23 showers)

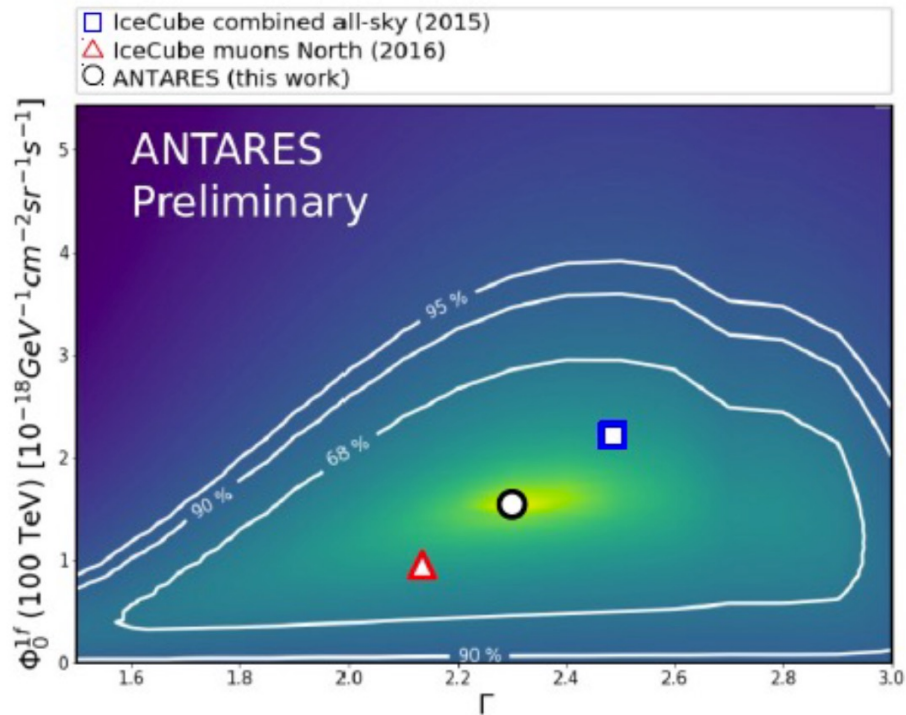

Background expectation (atm. flux, incl. prompt) :

$36.1 \pm 8.7$  (19.9 tracks and 16.2 showers) – stat. + syst.

Results not really constraining... but fully compatible with IceCube

# Combined (tracks+showers) likelihood fitting:

Cosmic:  $\Phi_{100 \text{ TeV}} = (1.5 \pm 1.0) \times 10^{-18} \text{ GeV}^{-1} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$   
 $\Gamma = 2.3 \pm 0.4$

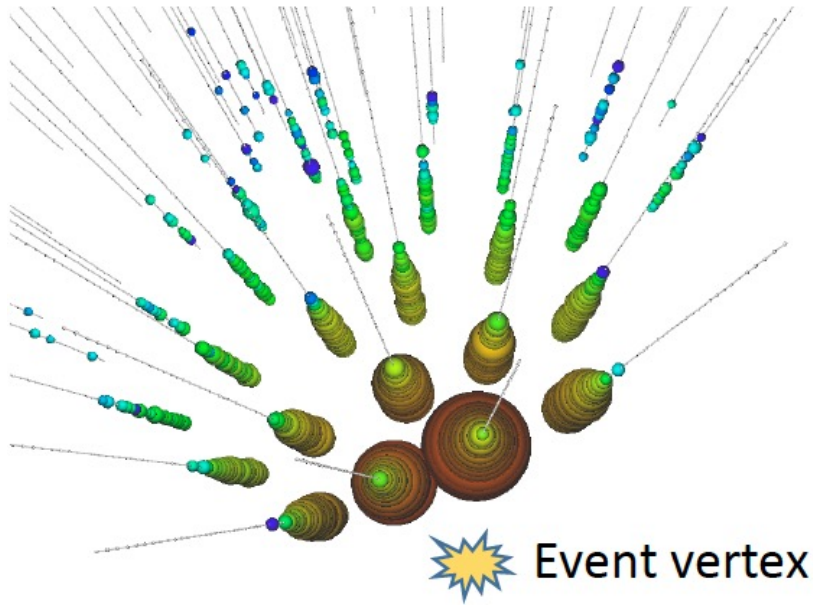

Results not really constraining... but fully compatible with IceCube

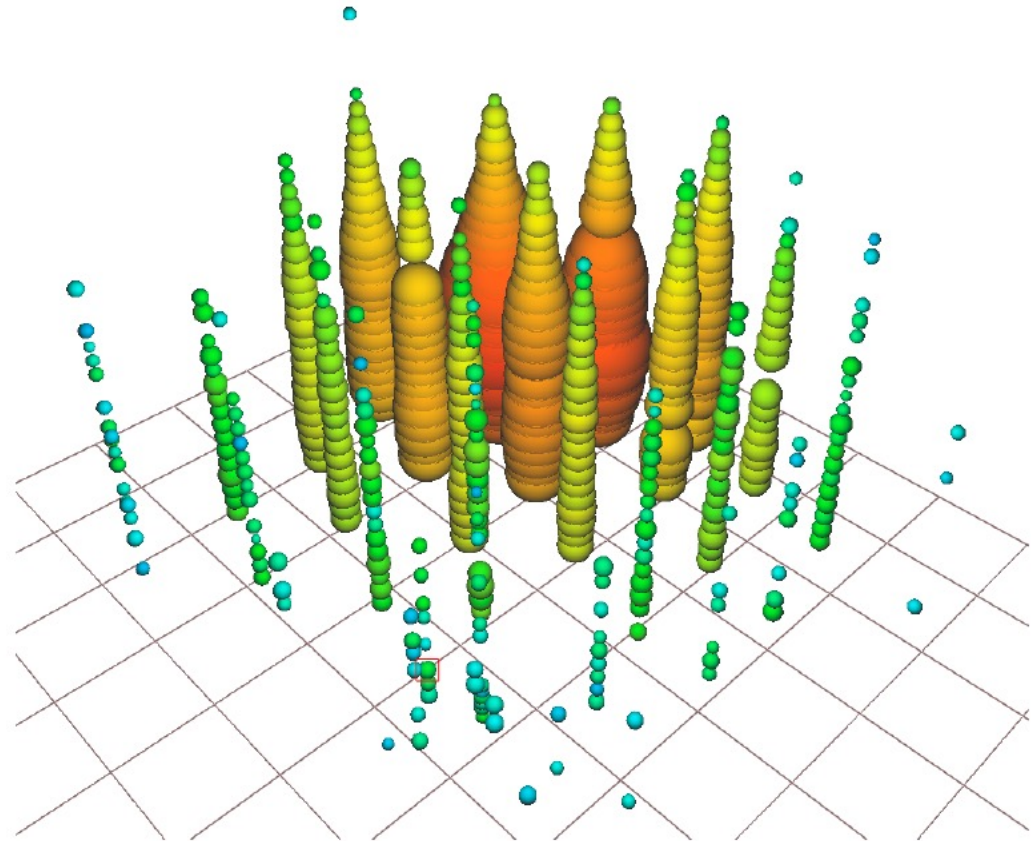

cosmic neutrinos: four independent observations  
exceeding  $5\sigma$

- muon neutrinos through the Earth
- starting neutrinos: all flavors
- tau neutrinos
- Glashow event

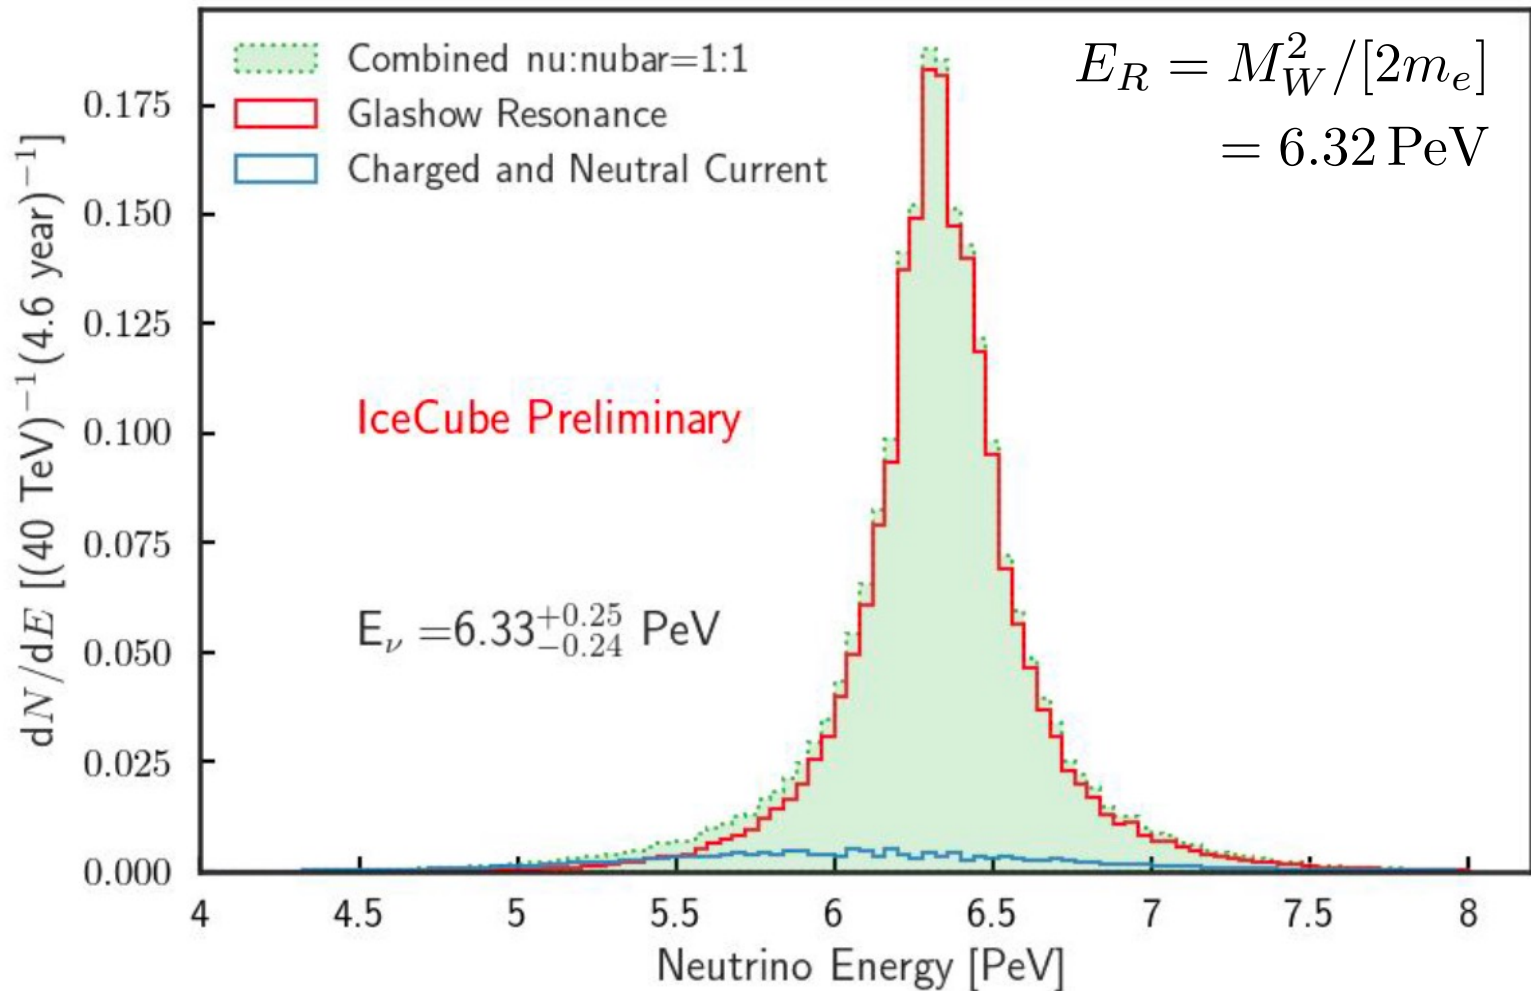

# partially contained event with energy 6.3 PeV

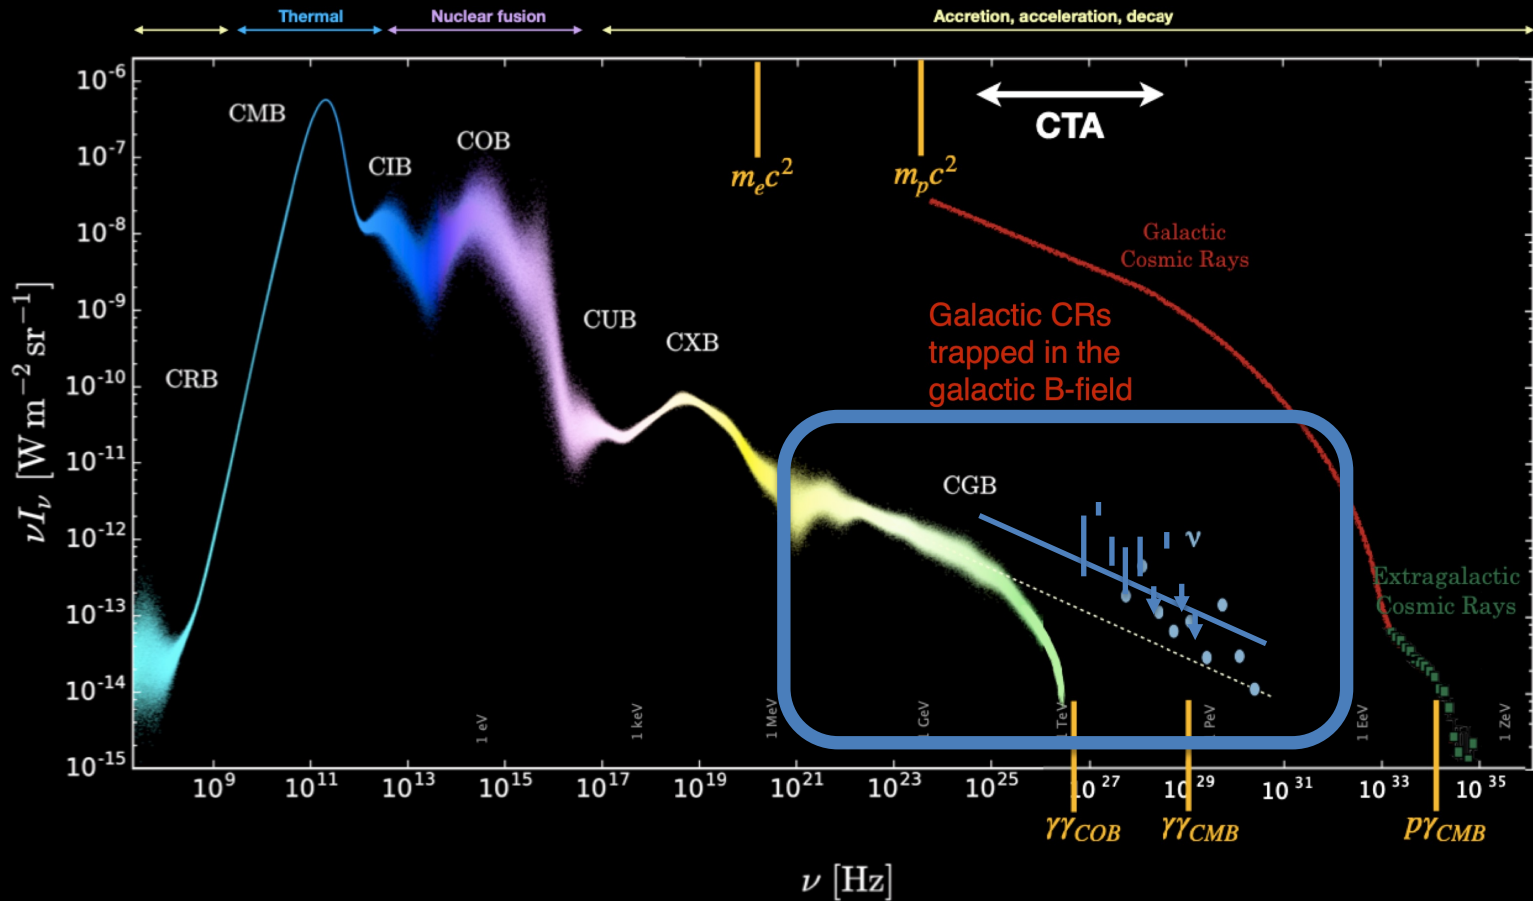

resonant production of a weak intermediate boson by an anti-electron neutrino interacting with an atomic electron

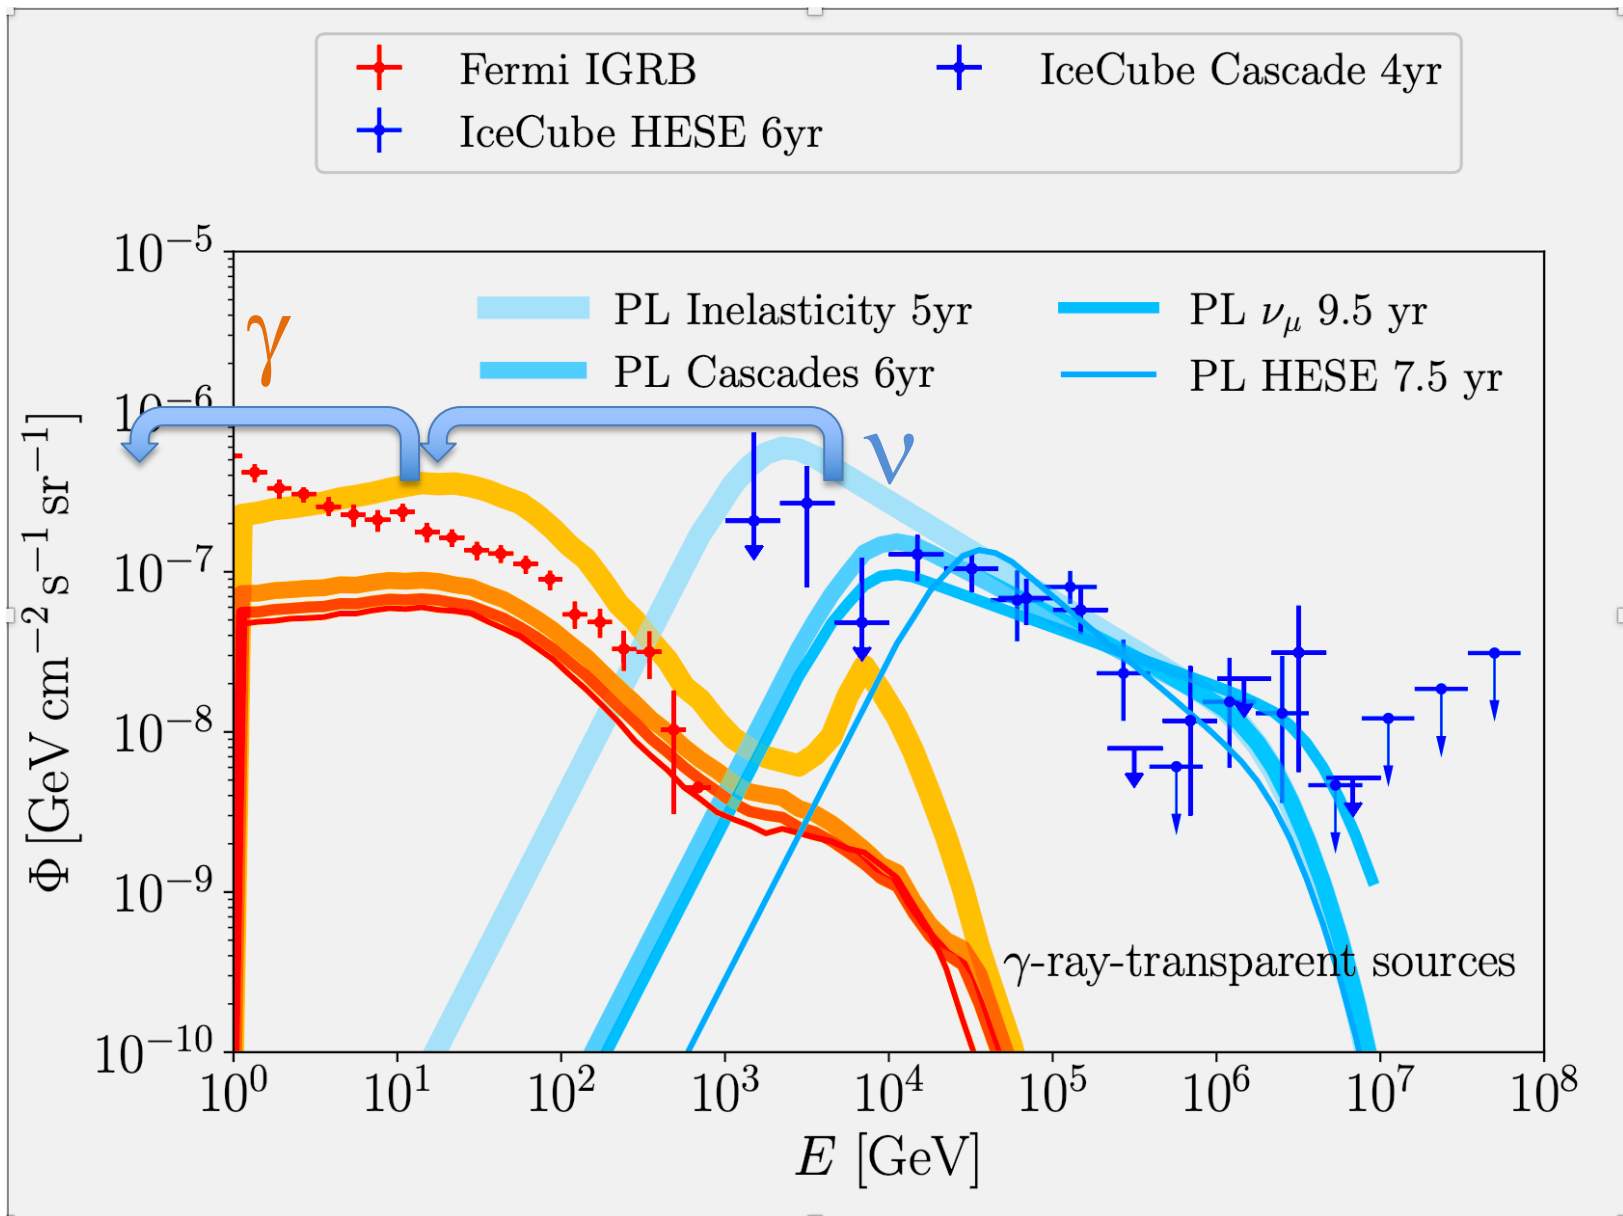

- energy measurement understood
- shower consistent with the hadronic decay of a weak intermediate boson  $W$
- identification of anti-electron neutrino

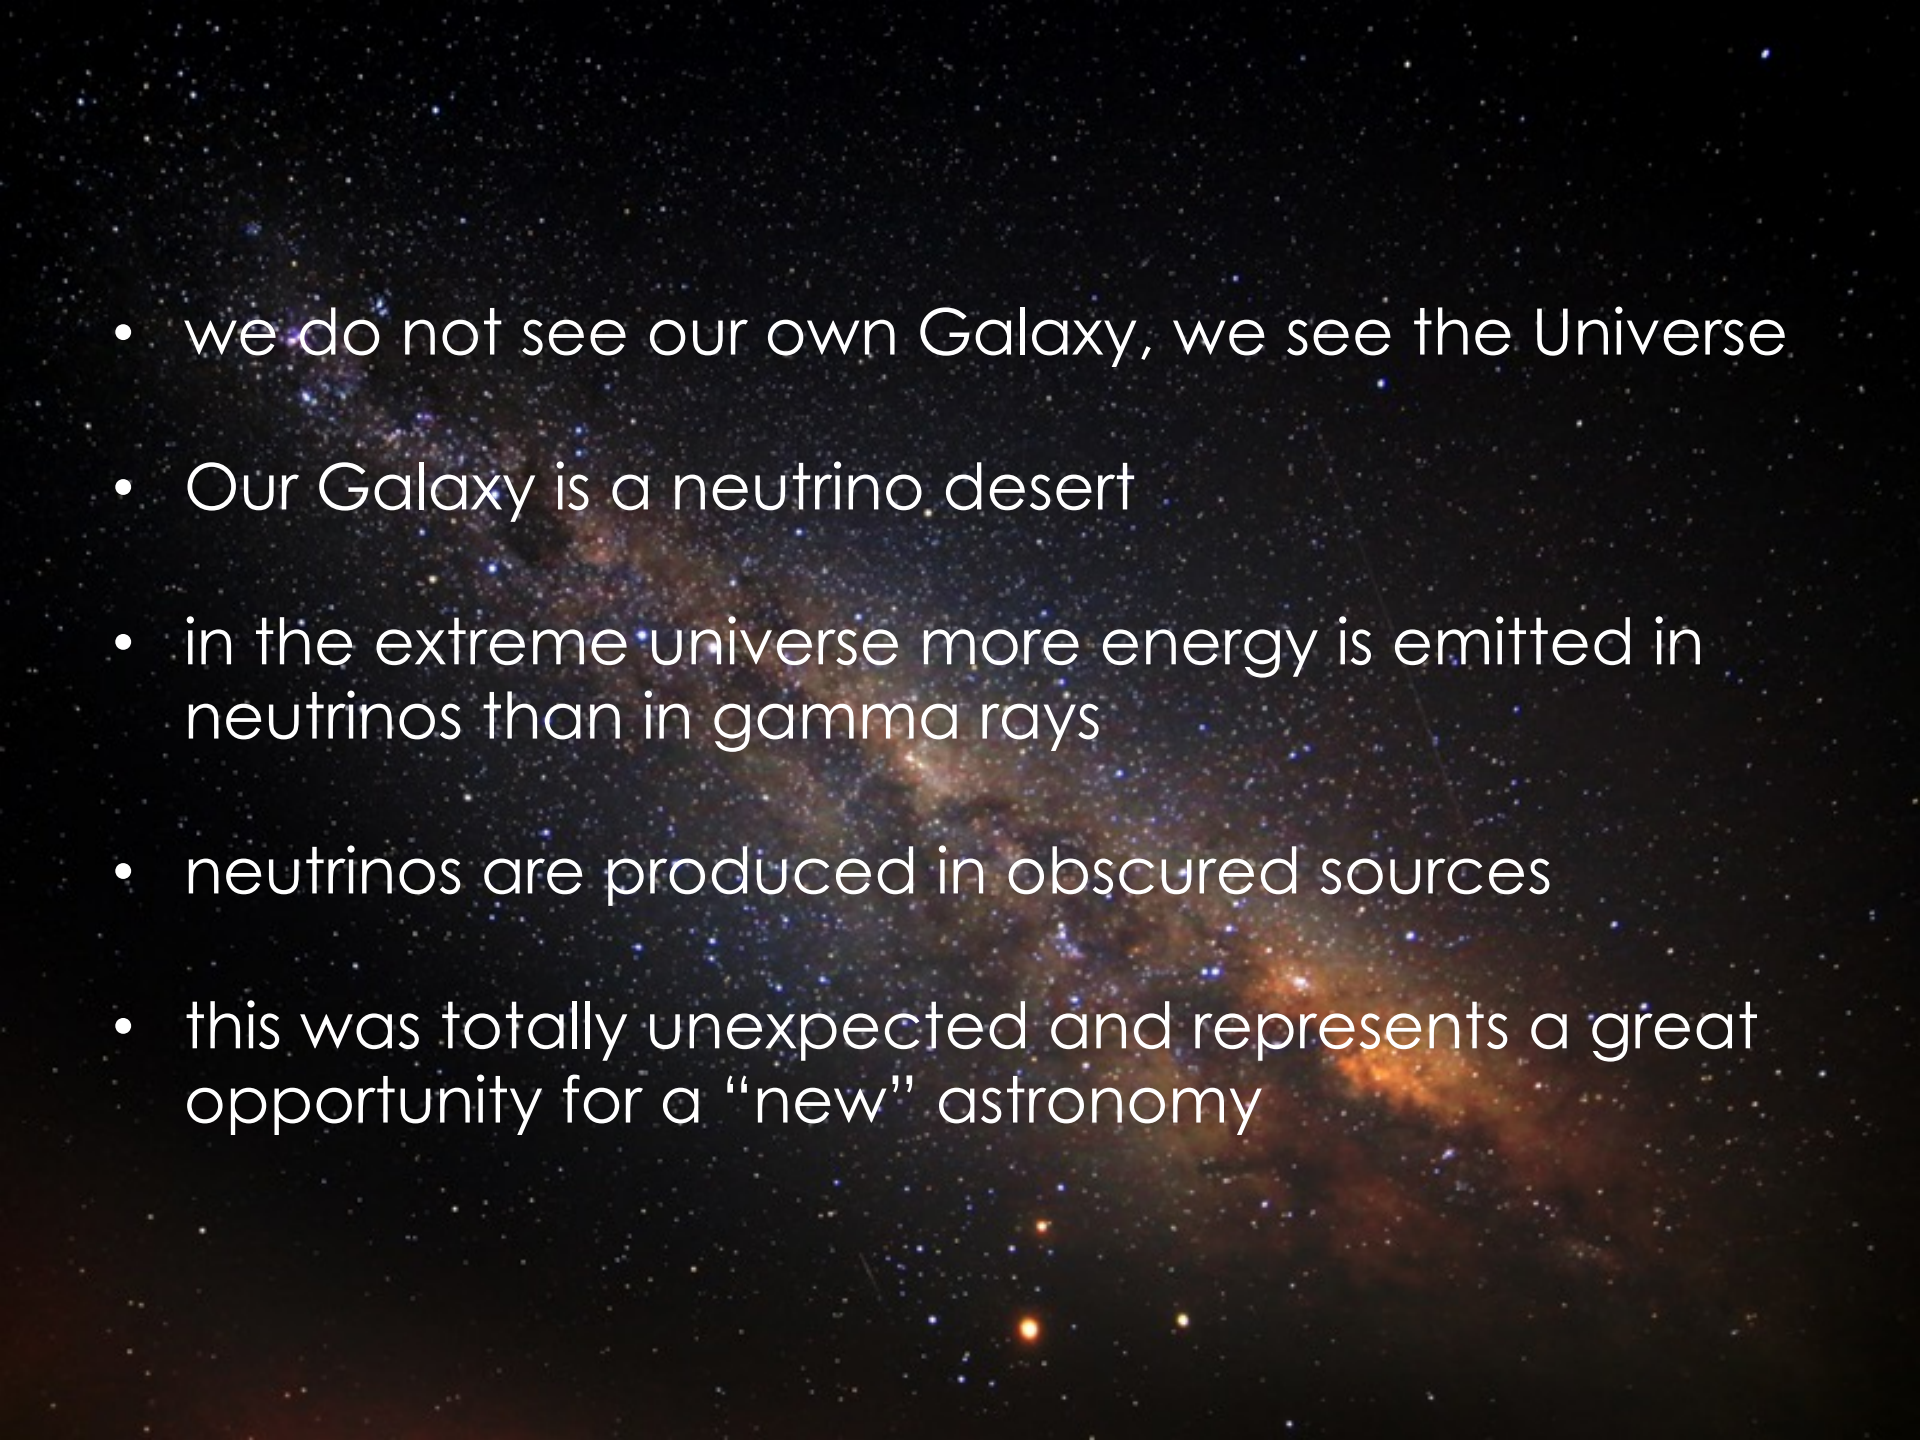

in the extreme universe the energy in neutrinos is larger than the energy in gamma rays

the neutrino sources are likely opaque to gamma rays

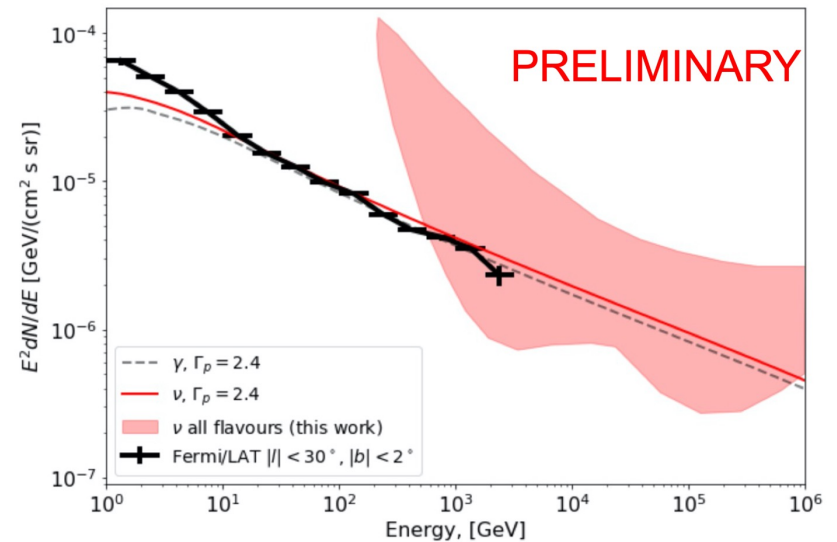

- 
- we do not see our own Galaxy, we see the Universe
  - Our Galaxy is a neutrino desert
  - in the extreme universe more energy is emitted in neutrinos than in gamma rays
  - neutrinos are produced in obscured sources
  - this was totally unexpected and represents a great opportunity for a “new” astronomy

# ANTARES: Galactic plane (preliminary)

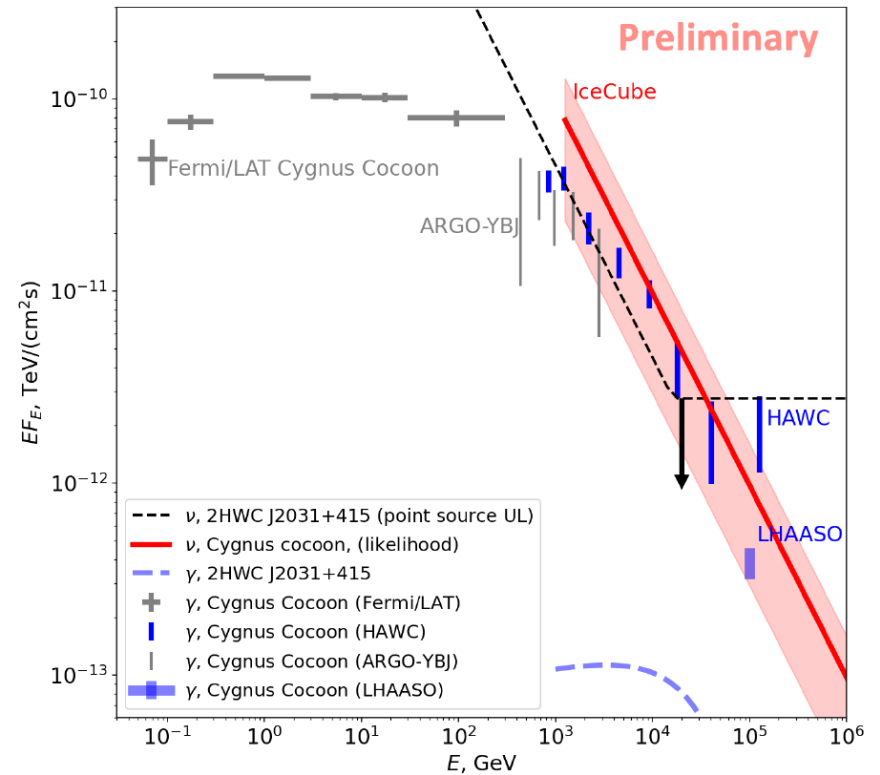

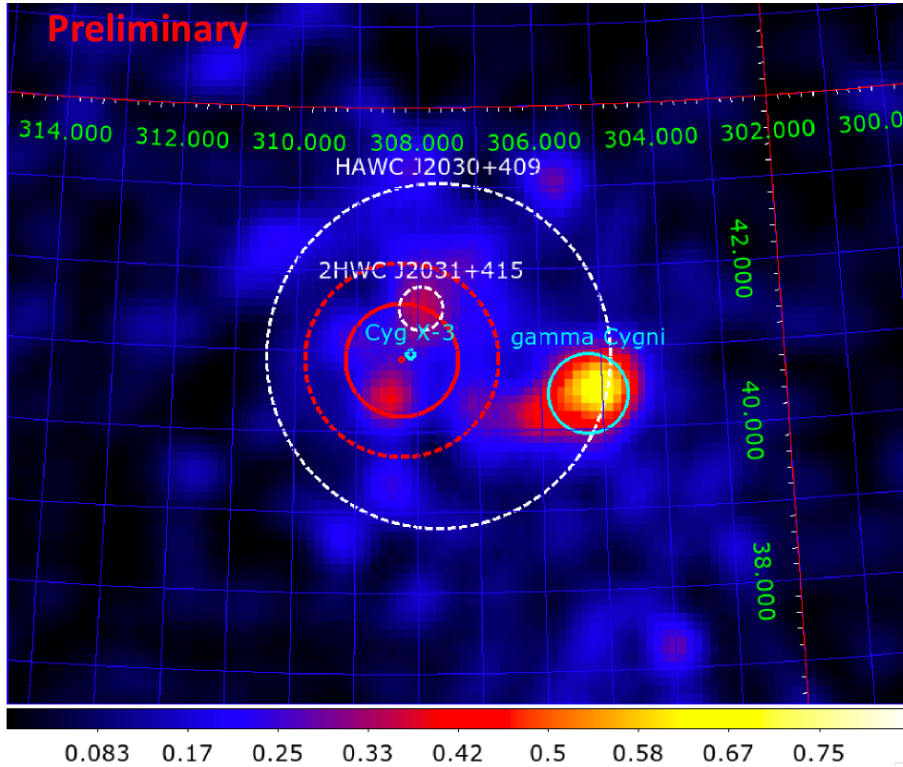

- **Data period:** 2007–2020
- **Events:** tracks + showers, using existing diffuse neutrino selections
- **Signal hypothesis:** looking for signal in the region  $|\ell| < 30^\circ$  and  $|b| < 2^\circ$  assuming a simple power-law

$$\frac{dN}{dE dt d\Omega} = \phi_0 \times \left( \frac{E}{40 \text{ TeV}} \right)^{-\gamma} \quad \text{in } [\text{GeV}^{-1} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}] \quad \text{per flavor}$$

**Best-fit:**  $\gamma = 2.45$ ,  $\phi_0(40 \text{ TeV}) = 4.0 \text{e-}16$

## Likelihood analysis of Cygnus X region

Source position is consistent with either HAWC or LHAASO extended source position.

Neutrino flux level is consistent with the  $\gamma$ -ray flux of the extended Cocoon source.

# High-Energy Cosmic Neutrinos

francis halzen

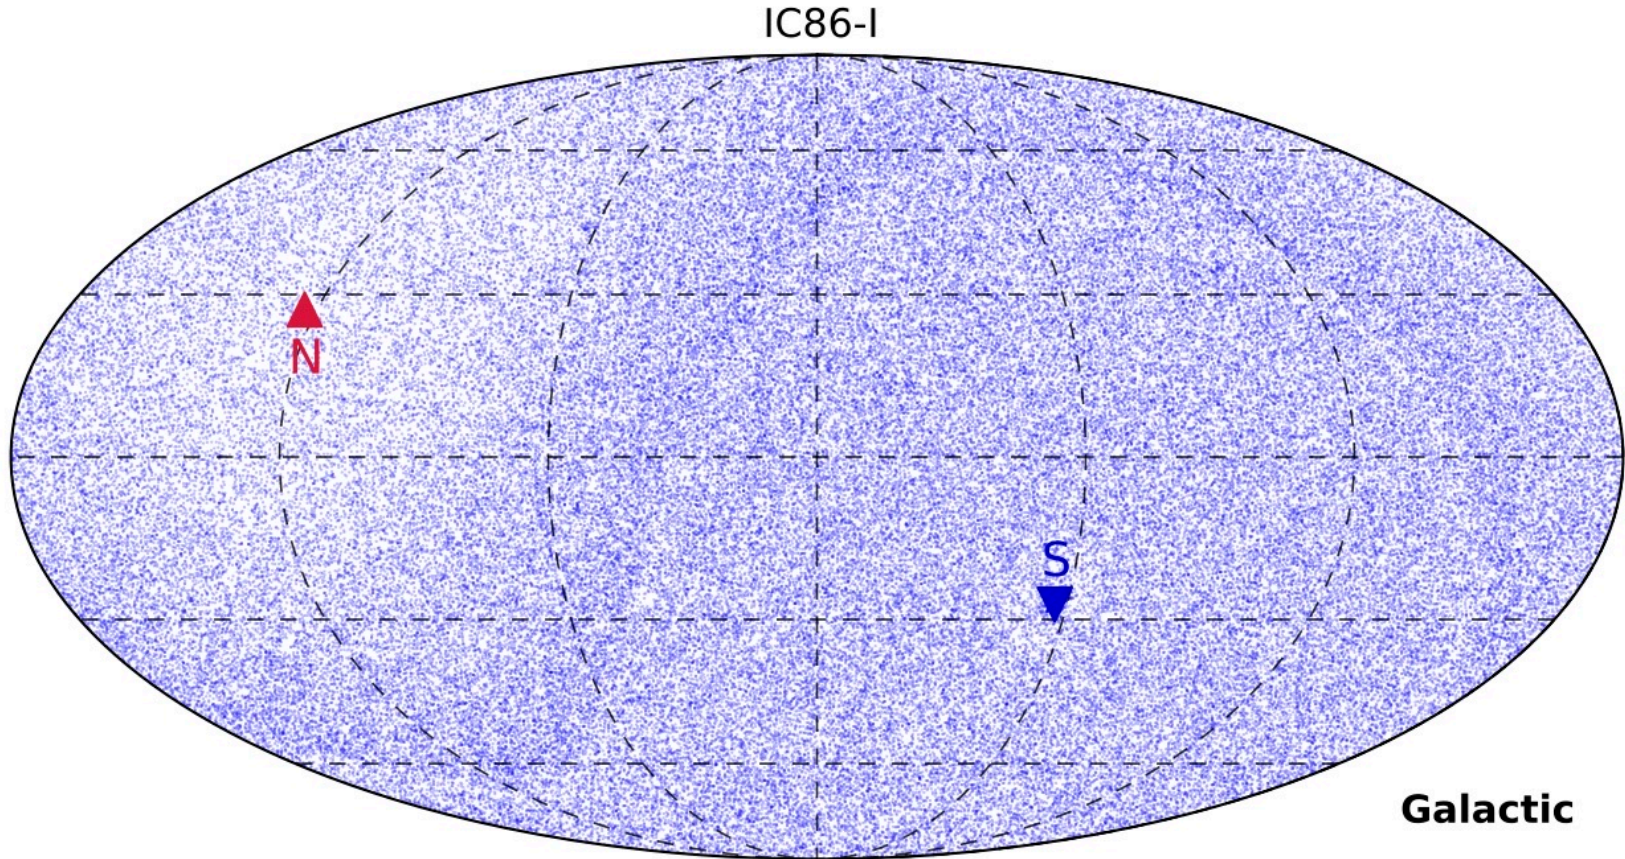

ICECUBE

- ANTARES, Baikal-GVD, IceCube
- the diffuse high-energy neutrino flux
- observation of the first sources
- multimessenger astronomy: plan B

# one year of IceCube neutrinos $>100$ GeV

(reaches neutrino purity of 97% but overwhelmingly atmospheric)

138322 neutrino candidates in one year

~ 200 cosmic neutrinos

~12 separated from atmospheric background with  $E > 60$  TeV

- maximize the likelihood  $L$  at each point in the sky
- usually, add energy term to the signal likelihood  $S$

$$L(n_s, x_s, \gamma) = \prod_i^{\text{events}} \left( \frac{n_s}{N} S_i(|x_i - x_s| \sigma_i, E_i, \gamma) + \frac{N - n_s}{N} B_i(\delta_i, E_i) \right)$$

$$\downarrow$$

$$S_i(|\vec{x}_i - \vec{x}_s|, \sigma_i) = \frac{1}{2\pi\sigma_i^2} \exp\left(-\frac{|\vec{x}_i - \vec{x}_s|^2}{2\sigma_i^2}\right)$$

# evidence for non-uniform sky map in 10 years of IceCube data : mostly resulting from 4 extragalactic source candidates

pre-trial p-value for clustering of high energy neutrinos

limits and interesting fluctuations ?

a rotating supermassive  
black hole

Illustration

# NGC 1068: an obscured cosmic accelerator

# neutrino production in obscured cores of active galaxies

- electrons and protons are accelerated in the high field regions associated with the black hole and the accretion disk
- produce neutrinos in the optically thick corona

# NGC 1068 neutrinos: the disk corona model

the radiatively obscured core of an active galaxy: opaque to  $\gamma$ -rays

[PS: the neutrinos are not produced by star formation because they are not accompanied by gamma rays]

# NEUTRINO BEAMS

## the $p\gamma$ efficiency dilemma

- efficiency for producing the neutrinos in the photon target:

$$\tau_{p\gamma} \simeq \frac{\kappa_{p\gamma} R_{\text{escape}}}{\lambda_{p\gamma}} \simeq R_{\text{escape}} \sigma_{p\gamma} n_{\text{photons}}$$

- likelihood of the multimessenger photons to be absorbed in target

$$\tau_{\gamma\gamma} \simeq R_{\text{target}} \sigma_{\gamma\gamma} n_{\text{photons}}$$

→ therefore, with  $R_{\text{escape}} \sim R_{\text{target}}$

$$\tau_{\gamma\gamma} \sim \frac{\sigma_{\gamma\gamma}}{\sigma_{p\gamma}} \tau_{p\gamma} \sim 300 \tau_{p\gamma}$$

→ do not expect high energy gamma rays to accompany cosmic neutrinos

→ blazar jets are out

# neutrinos produced in the gamma-ray obscured core of NGC 1068

accompanying pionic photons

range of neutrino flux:  
protons versus electrons

the cocoon absorbs the protons to produce neutrinos

by dimensional analysis:

$$\tau_{\gamma\gamma} \simeq 10^5 \left[ \frac{R_s}{R} \right] \left[ \frac{1 \text{ keV}}{E_X} \right] \left[ \frac{L_X}{L_{edd}} \right] \sim 300 \tau_{p\gamma}$$

NGC 1068:

$$E_X = 1 \text{ keV}; L_X \sim 10^{43} \text{ ergs}^{-1} \text{ and } M = 10^7 M_{\text{sun}}$$

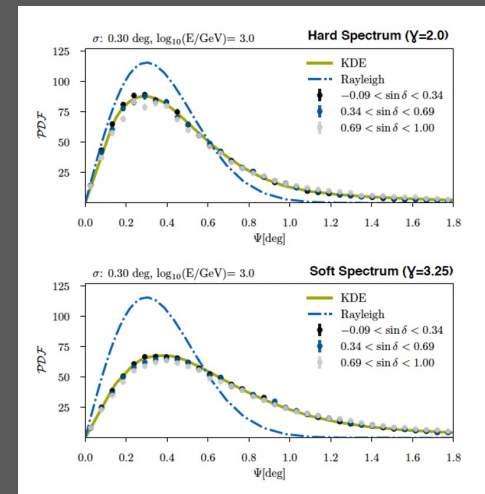

the size of the neutrino production region (or the gamma ray absorption region for the case of pp) is 10 ~100 Schwarzschild radii!

$$R_s = [2GM]/c^2 = 3 \times 10^5 \text{ cm} \left[ \frac{M}{M_{\text{sun}}} \right] \simeq 0.1 R$$

$$L_{edd} = \frac{4\pi GMm_p c}{\sigma_T} = 1.2 \times 10^{38} \frac{\text{erg}}{\text{s}} \left[ \frac{M}{M_{\text{sun}}} \right] \simeq 10^2 L_X$$

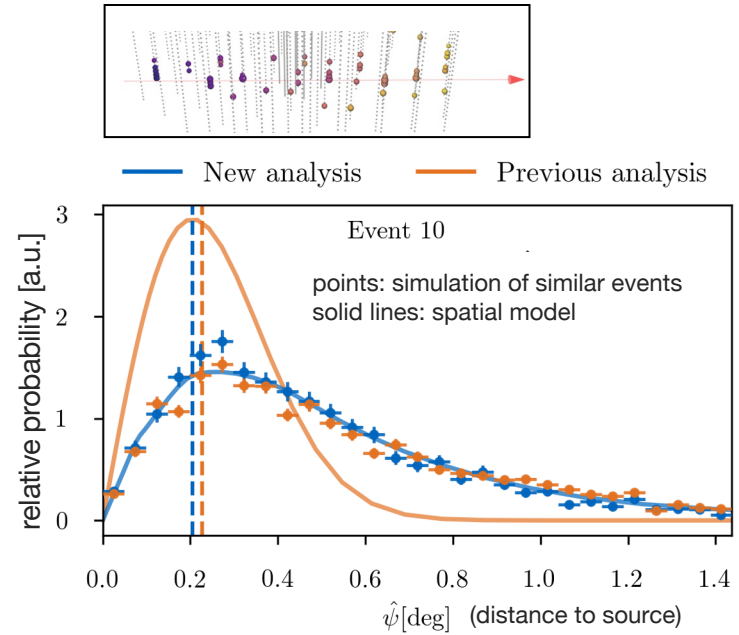

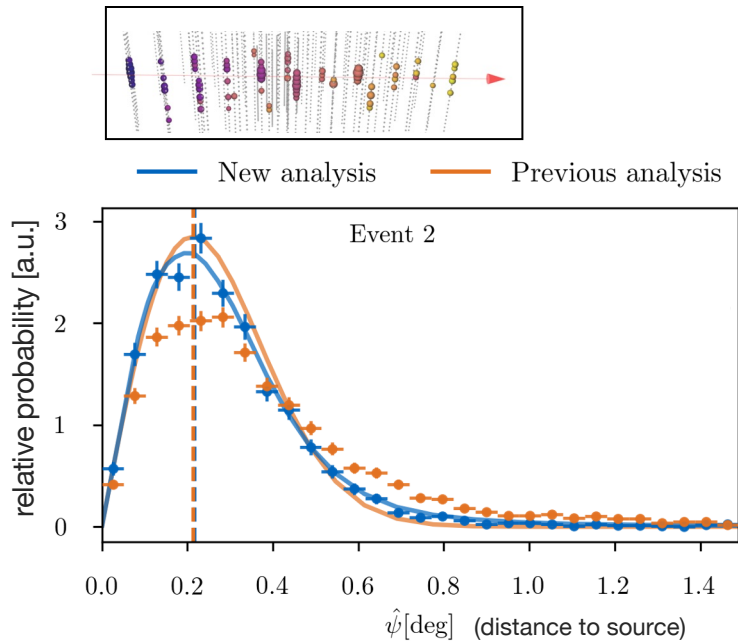

# interesting fluctuations or neutrino sources?

- improved detector geometry and calibration (each PMT calibrated individually)
- improved muon angular resolution and energy reconstruction
  - DNN (energy) and BDT (pointing) reconstruction
  - *point spread function consistent with simulation*
  - insensitive to systematics
  - improved characterization of the optics of the ice

applied to 10 years of archival data (pass 2),  
data unblinded, answer...

## pointing with neutrinos:

## directional distributions:

- better modeling of the directional distribution of neutrinos
- consistent with full Monte-Carlo simulations of the detector

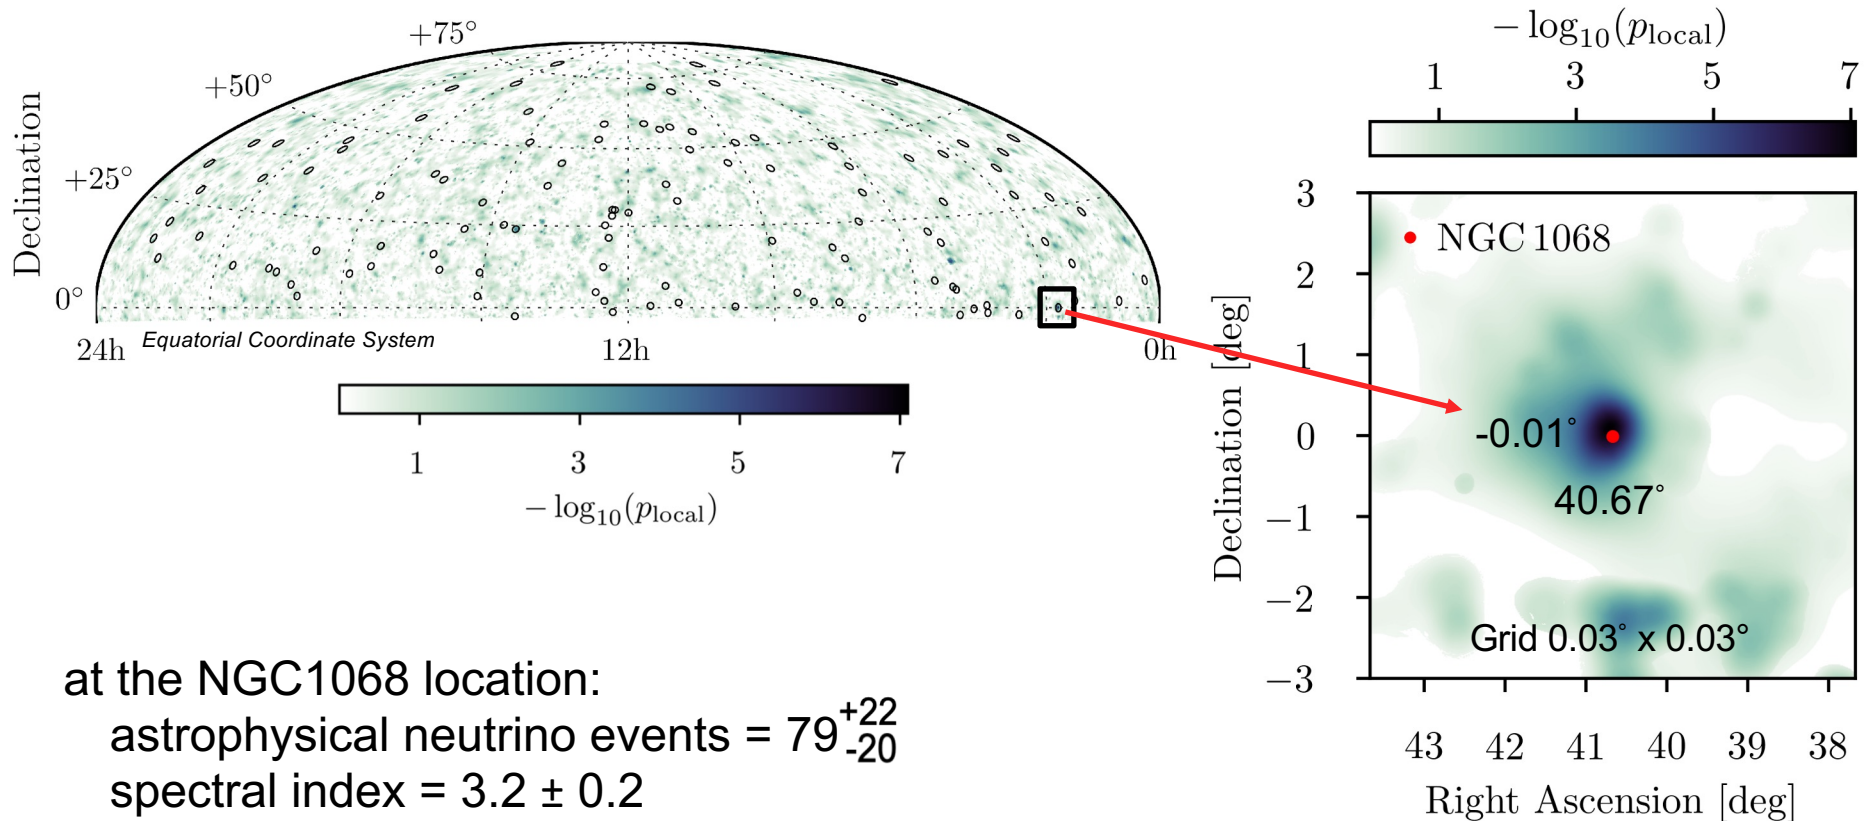

# the new IceCube neutrino map

the brightest location in full sky scan:  
astrophysical neutrino events = 81  
spectral index = 3.2  
local significance  $5.3\sigma$

1% of scrambled data sets have a spot  $\geq 5.3\sigma$

is the hot spot coincident with one of the 110 preselected sources?

at the NGC1068 location:

astrophysical neutrino events =  $79^{+22}_{-20}$

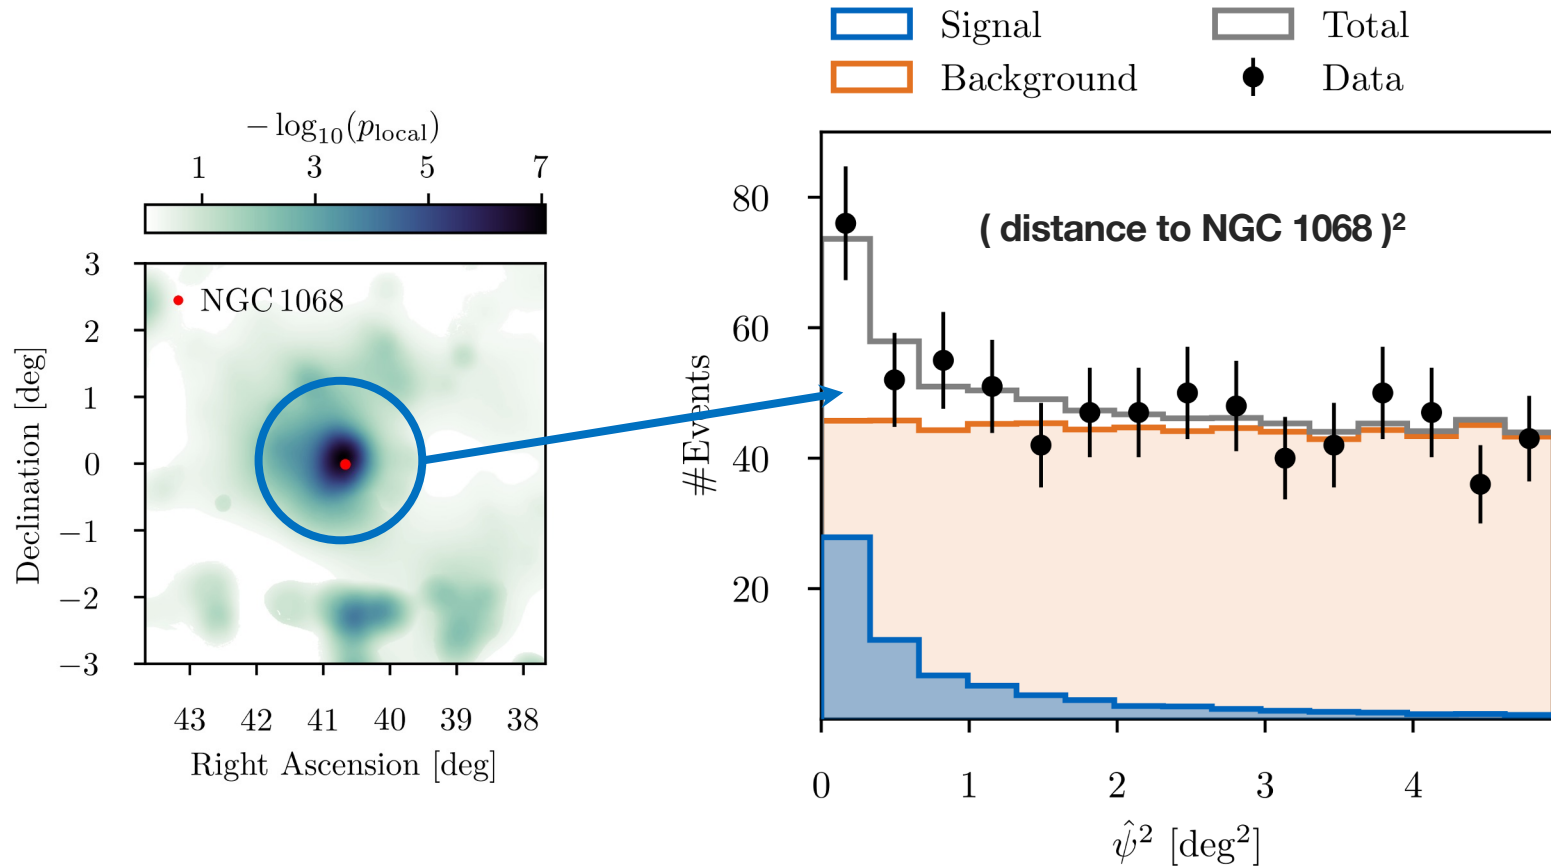

spectral index =  $3.2 \pm 0.2$

single source significance  $5.2\sigma$

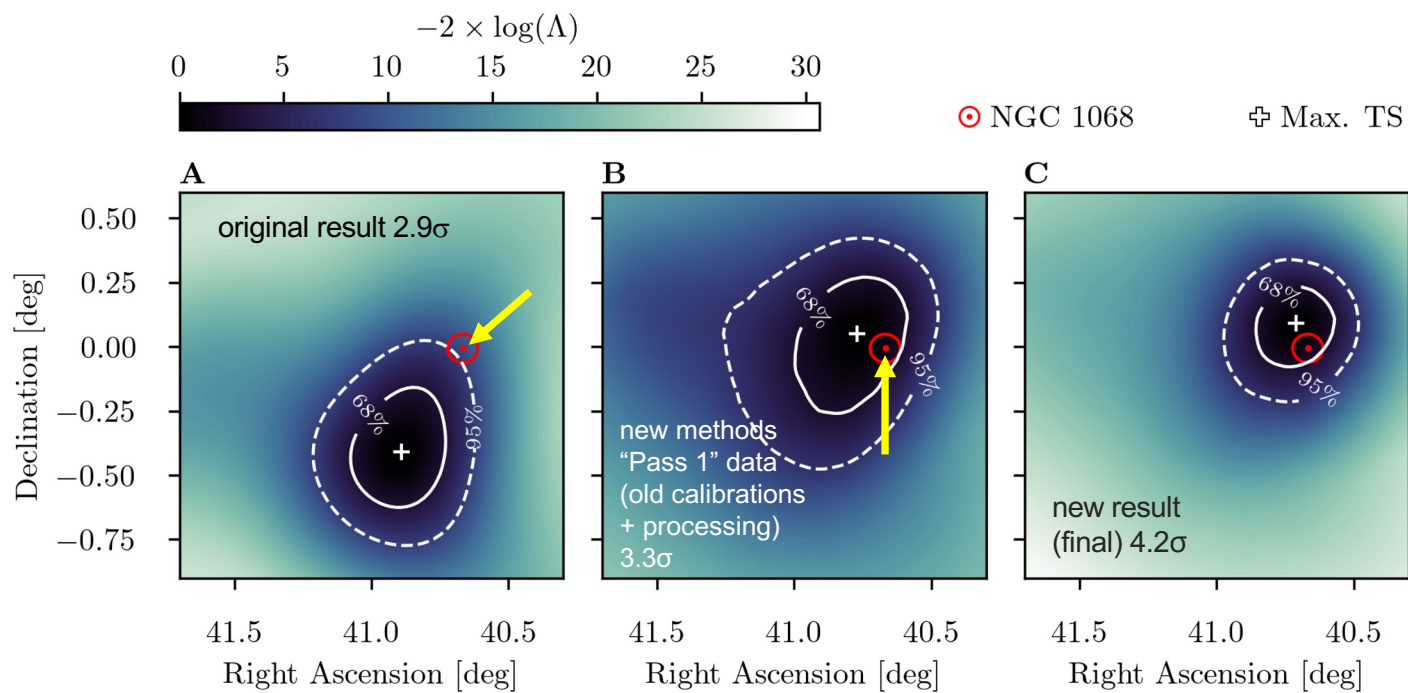

1 in 100,000 scrambled data sets have object  $\geq 5.2 \sigma = 4.2 \sigma$  evidence

# another look at the result

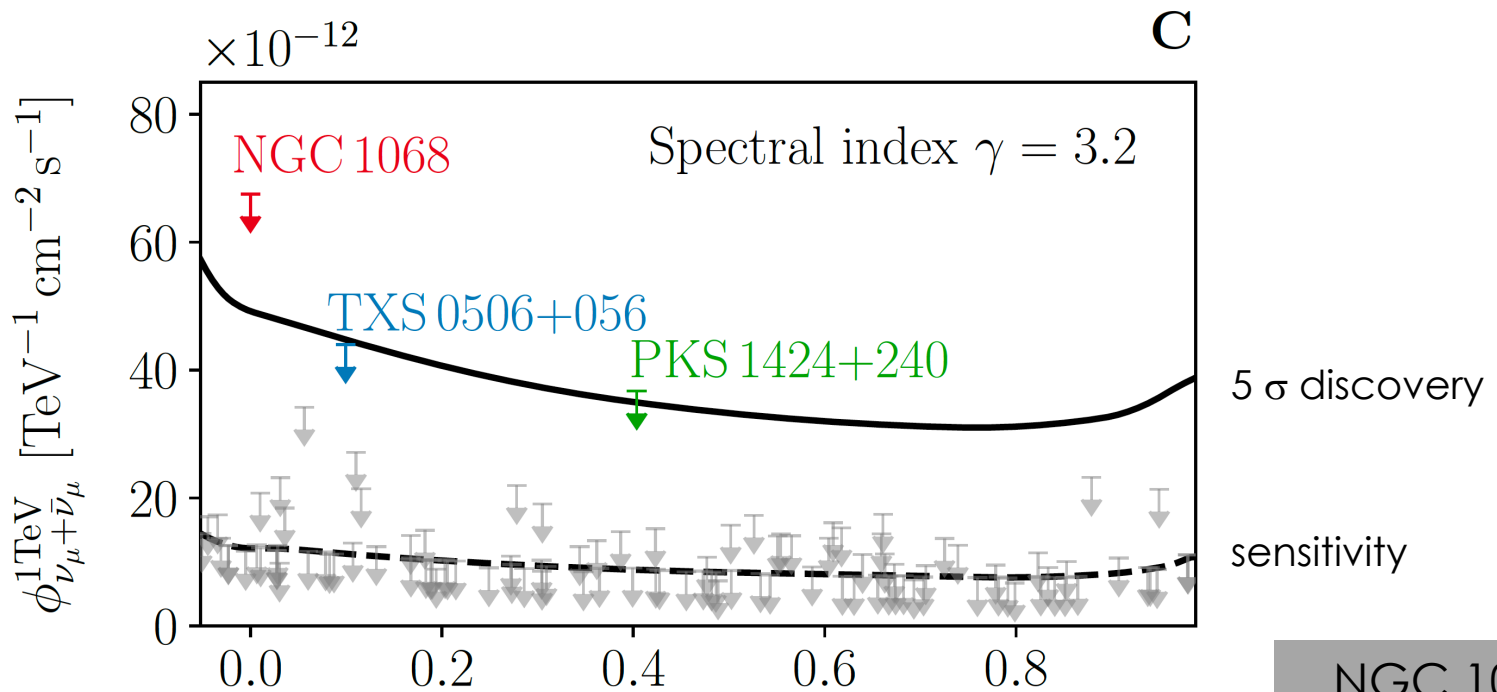

- measured astrophysical neutrino events =  $79^{+22}_{-20}$
- the angular distribution of the events matches simulation

limits and interesting fluctuations ?

### NUCLEAR EMISSION IN SPIRAL NEBULAE\*

CARL K. SEYFERT†

**1943**

#### ABSTRACT

Spectrograms of dispersion 37–200 Å/mm have been obtained of six extragalactic nebulae with high-excitation nuclear emission lines superposed on a normal G-type spectrum. All the stronger emission lines from  $\lambda 3727$  to  $\lambda 6731$  found in planetaries like NGC 7027 appear in the spectra of the two brightest spirals observed, NGC 1068 and NGC 4151.

## How are neutrinos produced in non-jetted AGN?

We conclude that active galactic accelerating particles to cosmic galactic cosmic rays is likely to particular, in the Virgo supercluster NGC 4151 and NGC 1068 are likely "local" metagalactic cosmic rays. the ultra-high energy ( $E \gtrsim 10^{19}$  eV) air showers. The energy density of photons in the immediate vicinity of a black hole may be too high (Blumenthal, 1970) to permit the acceleration of protons beyond  $\sim 10^{14}$  eV, (except by beaming processes). The highest energy protons hence are accelerated somewhat farther out, or else by beaming (Lovelace, 1976). Gamma rays from the ergosphere of a black hole are degraded at energies above  $\sim 1$  MeV, and from a spinar, above  $\sim 1$  GeV. Neutrinos are not thus affected and would provide information on very high energy particles in active galactic nuclei.

## RESEARCH ARTICLE SUMMARY

NEUTRINO ASTROPHYSICS

# Multimessenger observations of a flaring blazar coincident with high-energy neutrino IceCube-170922A

The IceCube Collaboration, *Fermi*-LAT, MAGIC, *AGILE*, ASAS-SN, HAWC, H.E.S.S., *INTEGRAL*, Kanata, Kiso, Kapteyn, Liverpool Telescope, Subaru, *Swift*/*NuSTAR*, VERITAS, and VLA/17B-403 teams\*†

## RESEARCH ARTICLE

NEUTRINO ASTROPHYSICS

# Neutrino emission from the direction of the blazar TXS 0506+056 prior to the IceCube-170922A alert

IceCube Collaboration\*†

IceCube 170922  
290 TeV

Fermi  
detects a flaring  
blazar within 0.06°

MAGIC  
detects emission of  
> 100 GeV gammas

# MASTER robotic optical telescope network: after 73 seconds

## Follow-up detections of IC170922 based on public telegrams

search in archival IceCube data:

- 100-day flare in 2014
- spectrum  $E^{-2.2}$
- $L_\nu > 10^{47}$  erg/s
- no gamma ray flare!

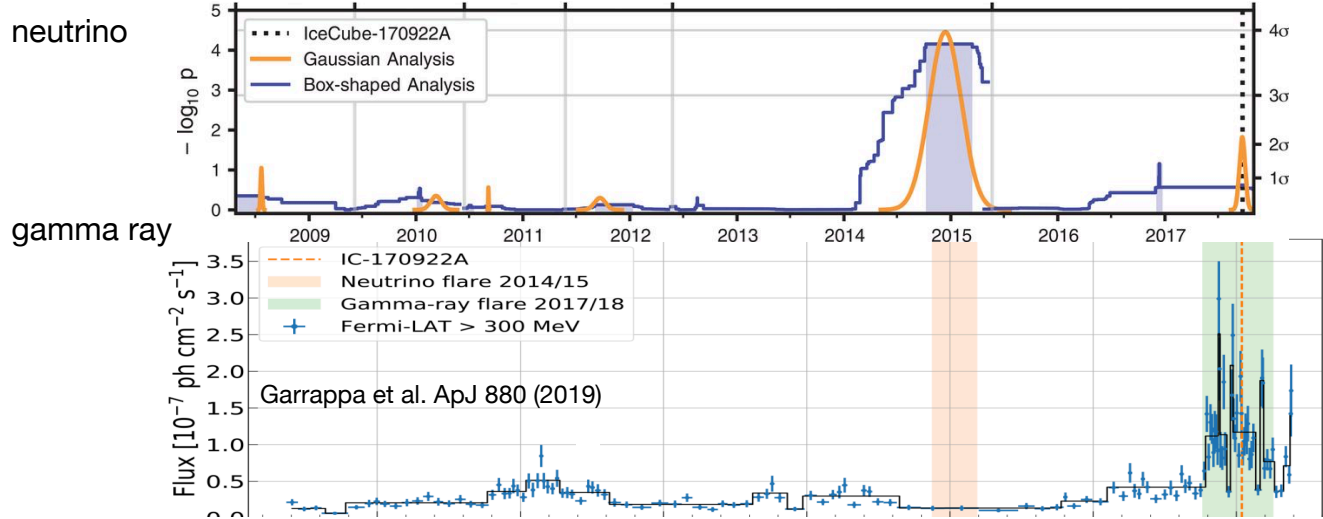

global robotic network of  
optical telescopes  
connects TXS 0506+056  
to IC170922A in the time  
domain

“MASTER found the blazar in the off-state *after one minute*  
and then switched to on-state two hours after the event.  
The effect is observed at a 50-sigma significance level”

## Upward-going cascade **GVD210418CA**

MJD = 59322.94855324

Energy  $E = 224 \text{ TeV } (\pm 30\%)$

Distance from central string  $r = 70 \text{ m}$

Zenith angle =  $115^\circ$

RA =  $82.4^\circ$ , Dec =  $7.1^\circ$

Probability for the background-only hypothesis (stat.+sys.)

**P-value = 0.0033 ( $2.93\sigma$ )**

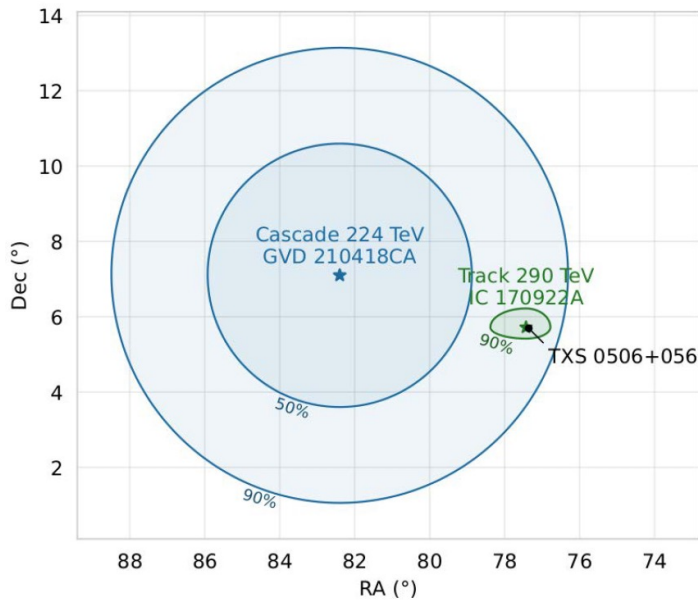

**Signalness: 97.1%**

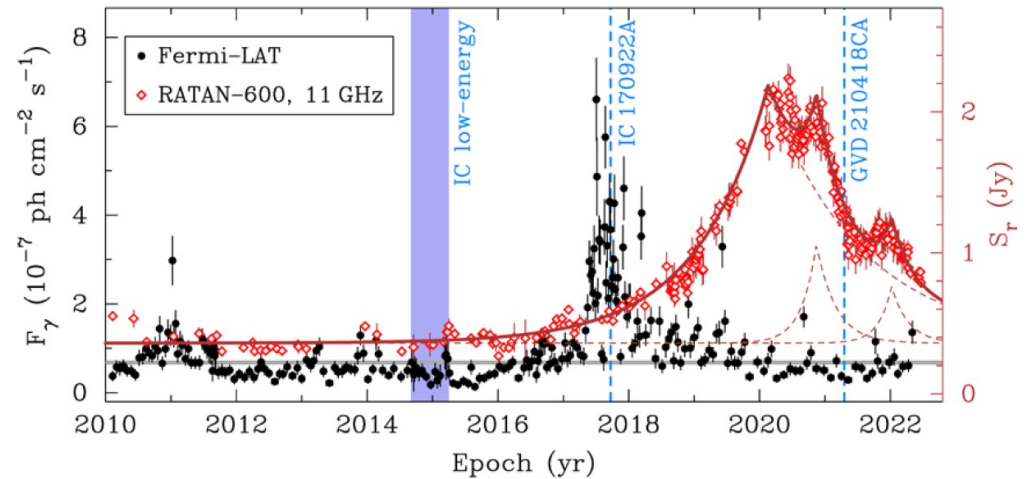

# A high energy neutrino from the direction of TXS 0506+056

**GVD210418CA** (97% signalness) lies within 90% error circle from TXS 0506+056

The chance probability for such an association to occur randomly due to the background is  $p = 0.0074$

Radio and gamma-ray light curves of TXS 0506+056.

Analysis of RATAN-600 radiotelescope data (11GHz) showed increased activity

- IC event registered during  $\gamma$  flare and radio activity
- Baikal-GVD event during radio activity
- Probability of IC non-observation: 11%

IC220918

within 90% error circle of TXS 0506+056

## TXS 0506+056

- two statistically independent observations above the  $> 3\sigma$  level
- it is also the second source in the all-sky search at  $3.7\sigma$
- high-statistic association of IC170922 with optical variation in time domain
- TXS 0506+056 within the error circle of IC220918 and the highest energy event observed by Baikal-GVD
- supported by TeV gamma ray and by radio imaging of the core (jet loses its tight collimation after 5 milliarcseconds)

NGC 1068

## neutrino astronomy 2022

- it exists
- more neutrinos, better neutrinos, more telescopes
- closing in on cosmic ray sources
- [are active galaxies with obscured cores the sources of cosmic rays?]

# Neutrinos? Perfect Messengers

- electrically neutral
- massless (in this talk)
- unabsorbed

• unlike  $\gamma$  rays, neutrinos are solely created in processes involving cosmic rays

- ... but difficult to detect

# multimessenger astronomy

- PeV  $\gamma$ 's lose energy on CMB photons
- gamma rays may also lose energy in the target that produces neutrinos even before reaching the EBL
- efficient neutrino production sites are likely to be optically thick to gamma rays; expect no correlation between gamma-ray and neutrino activity

10,000 times too small to  
do neutrino astronomy...

- 3 km deep glacier at geographic South Pole
- we transformed 1 km<sup>3</sup> of Antarctic ice below 1.5 km into a Cherenkov detector

### GCN notice for starting track sent Apr 27

We send **rough reconstructions first** and then **update them.**

from light in the ice to astronomer in less than one minute

# electron and tau neutrinos (showers)

muon neutrinos through Earth (tracks)

# NEUTRINO BEAMS: HEAVEN & EARTH

- a target efficient at converting protons into neutrinos is unlikely to be transparent to high energy photons.
- IC170922? TXS 0506+056 is not a blazar when neutrinos are emitted as confirmed by gamma ray, optical and radio observations

# RADIO INTERFEROMETRY

- core brightening observed in a radio burst that started 5 years ago
- beyond 5 milliarcseconds the jet loses its tight collimation

Peak: 1256.0, RMS: 0.09, mJy/beam

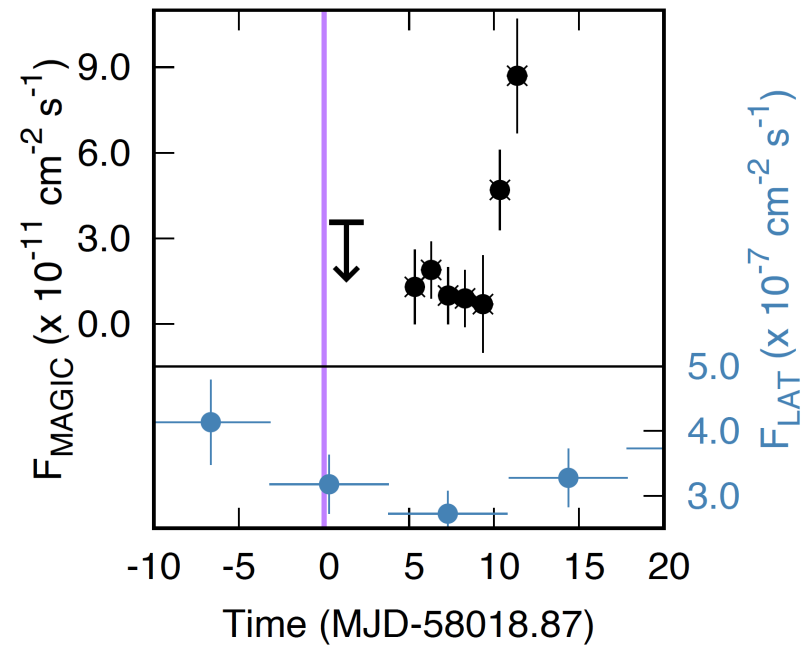

beyond 5 milliarcseconds the jet loses its tight collimation

- jet found a target after tens of pc to produce neutrinos
- obscures the gamma rays
- a massive star in the host galaxy, the jet of a merging galaxy, warped jet, structured jet...?

# gamma rays in 2017 at the time the neutrino is produced ?

a few  $\sim 10$  GeV photons and not much else, consistent with an obscured source, not a blazar

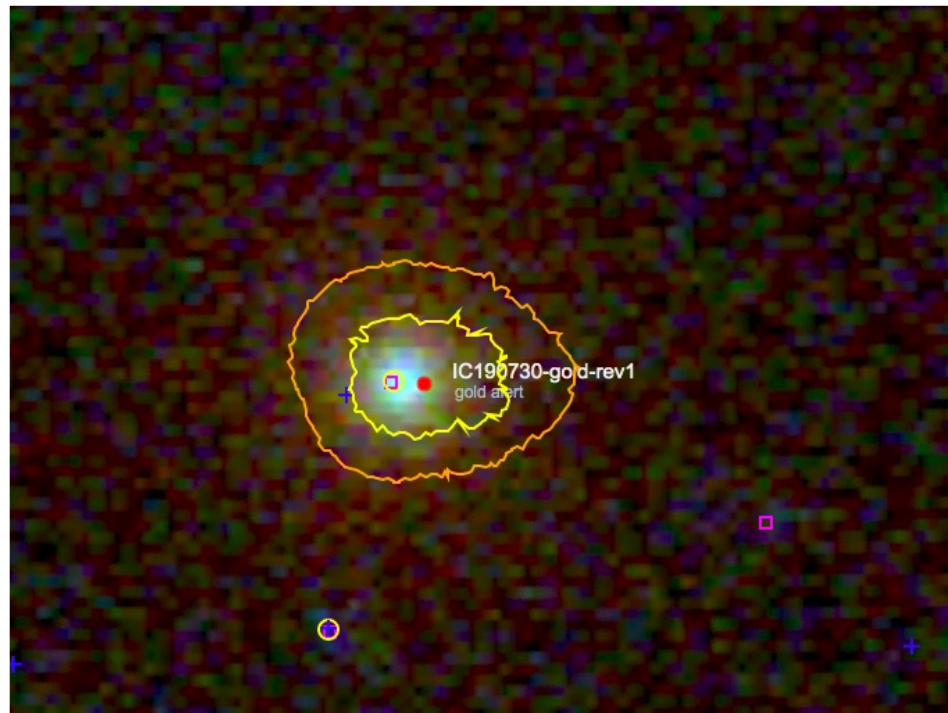

- MAGIC, HESS and VERITAS: no TeV gamma rays at the time the neutrino was produced
- MAGIC: onset of the TeV flux 5 days after IC170922
- confirmed by MASTER: the blazar switches from the “off” to “on” state 2 hours after the neutrino

# a second cosmic ray source ?

## Neutrino candidate source FSRQ PKS 1502+106 at highest flux density at 15 GHz

ATel #12996; *S. Kiehlmann (IoA FORTH, OVRO), T. Hovatta (FINCA), M. Kadler (Univ. Würzburg), W. Max-Moerbeck (Univ. de Chile), A. C.S. Readhead (OVRO) on 7 Aug 2019; 12:31 UT*  
*Credential Certification: Sebastian Kiehlmann (skiehlmann@mail.de)*

Subjects: Radio, Neutrinos, AGN, Blazar, Quasar

[Tweet](#)

On 2019/07/30.86853 UT IceCube detected a high-energy astrophysical neutrino candidate (ATel #12967). The FSRQ PKS 1502+106 is located within the 50% uncertainty region of the event. We report that the flux density at 15 GHz measured with the OVRO 40m Telescope shows a long-term outburst that started in 2014, which is currently reaching an all-time high of about 4 Jy, since the beginning of the OVRO measurements in 2008. A similar 15 GHz long-term outburst was seen in TXS 0506+056 during the neutrino event [IceCube-170922A](#).
