Two methods for spectroscopy

- Direct production in pp collisions
 - Usually combine a heavy flavour hadron with one or more light particles
 - Pros: High statistics, in principle can study all states
 - Cons: Large combinatorial background, hard to determine J^P

- Production by a heavier particle decay
 - Usually with amplitude analysis
 - Pros: Low background, Better determination of J^P
 - Cons: Low cross-section, limited mass range

Excited $\Omega_c \rightarrow \Xi_c^+ K^-$ states

- LHCb observed 5 narrow states (+ a possible wide one) in 2017
- Belle confirmed the first four states [PRD 97 (2018) 051102]

Ξ_b baryon spectroscopy

 - $\Xi_b^*(5945)^0 \rightarrow \Xi_b^- \pi^+$ [CMS'12]
 - $\Xi_b'(5935)^-, \Xi_b^*(5955)^- \rightarrow \Xi_b^0 \pi^-$ [LHCb'15]
 - $\Xi_b'^0$ not yet observed

New Ξ_c^{**0} from LHCb

[arXiv:2003.13649]

- Large statistics data shows Belle's $\Xi_c(2930)$ is a composite of two narrow Ξ_c^{**} 's
- A third peak is also seen
 - position close to kinematic limit of the B decay used by Belle

Feynman diagrams

- Two decays considered: $B^0 \rightarrow \bar{D}_s^+ D_s^- \pi^0$, $B^+ \rightarrow D^- D_s^+ \pi^+$ related by isospin symmetry

Open flavor tetraquark

- D0 (16') claimed evidence for the $X(5568)$ in decaying to $B_s \pi^+$, interpreted as tetraquark state $[b\bar{s}u\bar{d}]$
- But not seen in other experiments

First discovery of **open-charm tetraquark candidates with four different flavors** $[c\bar{s}u\bar{d}]$

- Resonant structures observed in the $D^- K^+$ system from an amplitude analysis of the $B^+ \rightarrow D^+ D^- K^+$ decay
