

# FORMATION CHANNELS OF BINARY BLACK HOLES: CLUSTERS *AND* BINARIES?

Astrid Lamberts

Laboratoire Lagrange/Laboratoire Artemis

Journées PNHE 7/9/23

# Masses in the Stellar Graveyard

LIGO-Virgo-KAGRA Black Holes LIGO-Virgo-KAGRA Neutron Stars EM Black Holes EM Neutron Stars

Where do these distributions come from?

# DIFFERENCES (BASED ON MODELS)

higher masses (2nd gen. + low  $Z$ )

equal masses preferred Unequal masses possible

spins aligned  
unclear spin amplitude

Isotropic distribution  
possibly high spins (2nd gen)

(often) long time delays

faster mergers possible?

Can explain BBH rate

Explains BNS/NSBH rate

too low BNS/NSBH rate

steeper redshift evolution?

Possibly detectable eccentricity?

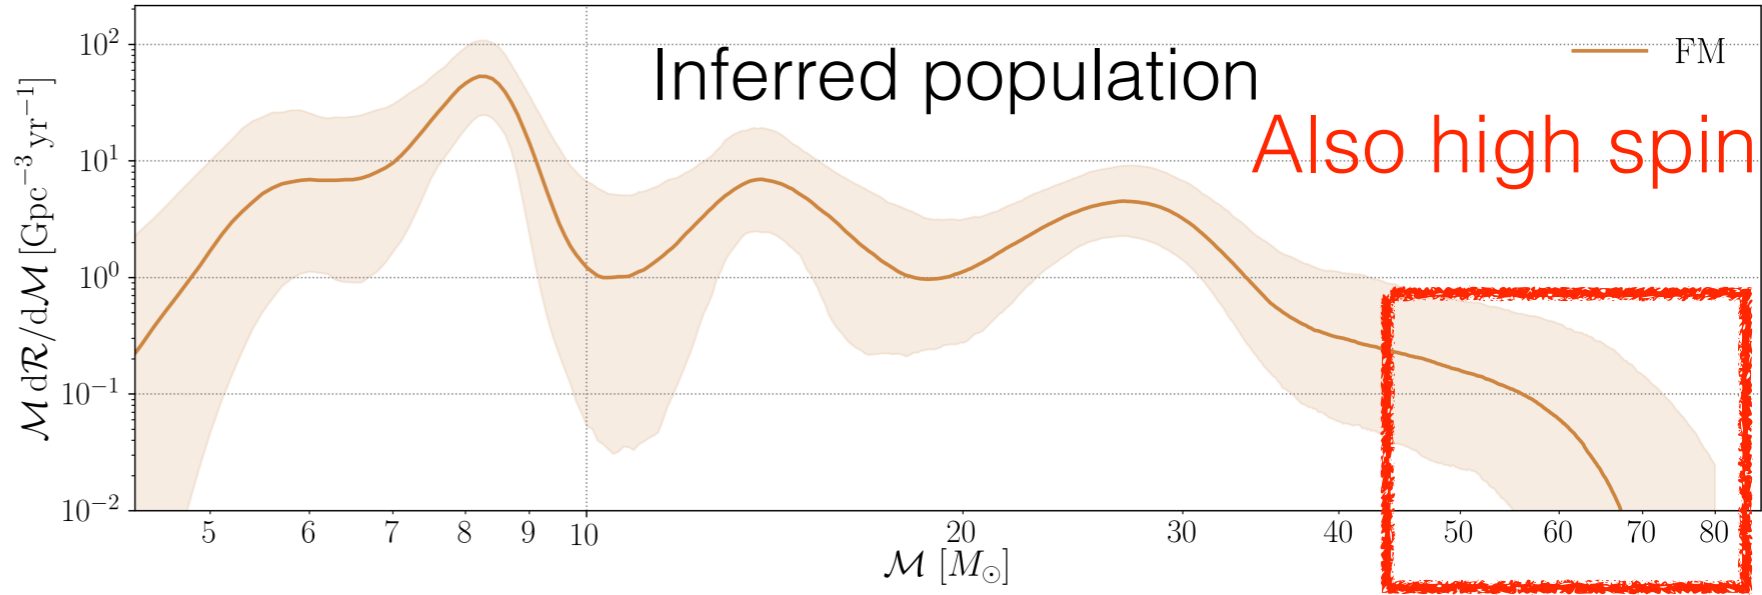

# DATA PREFERS AT LEAST TWO CHANNELS

High mass BHs challenge binary formation (e.g GW190521)

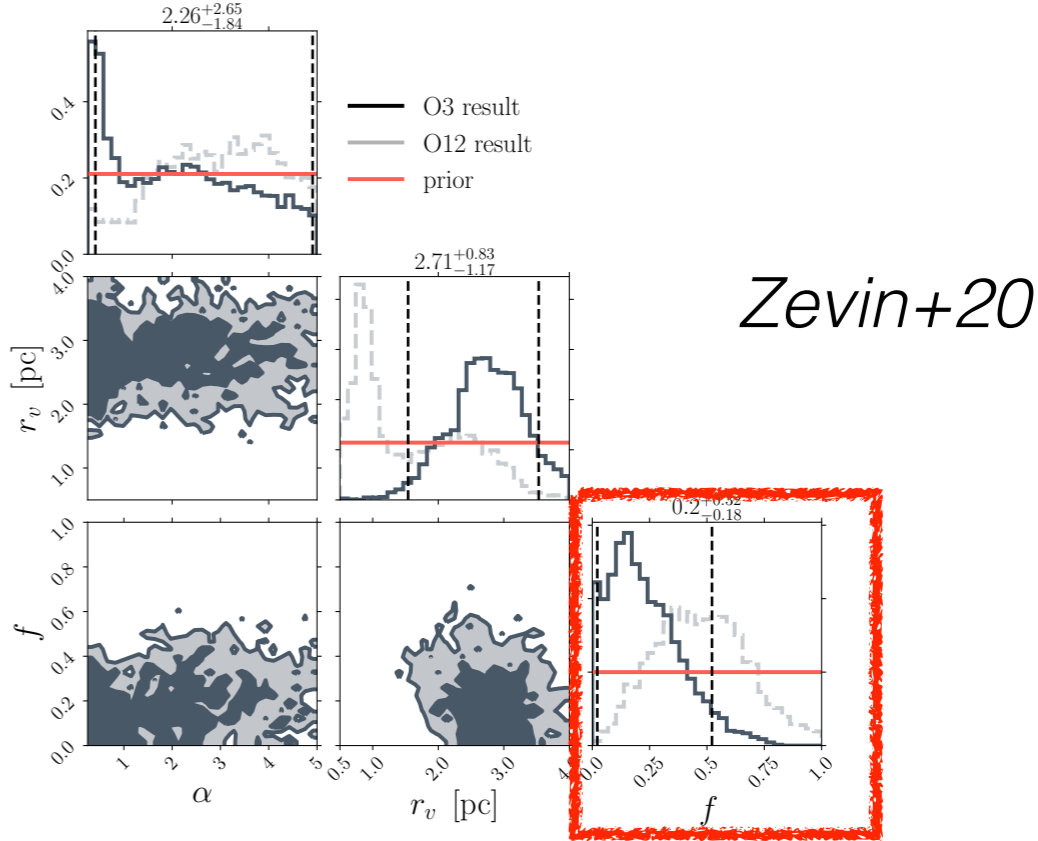

Spins suggest 2 populations

« Simple » astro modes: at least two merger channels (Zevin+20, Wong+20, Kimball+20, Bouffanais+21)

More data -> need for better models

LVC: GWTC-3 populations paper based on O3a

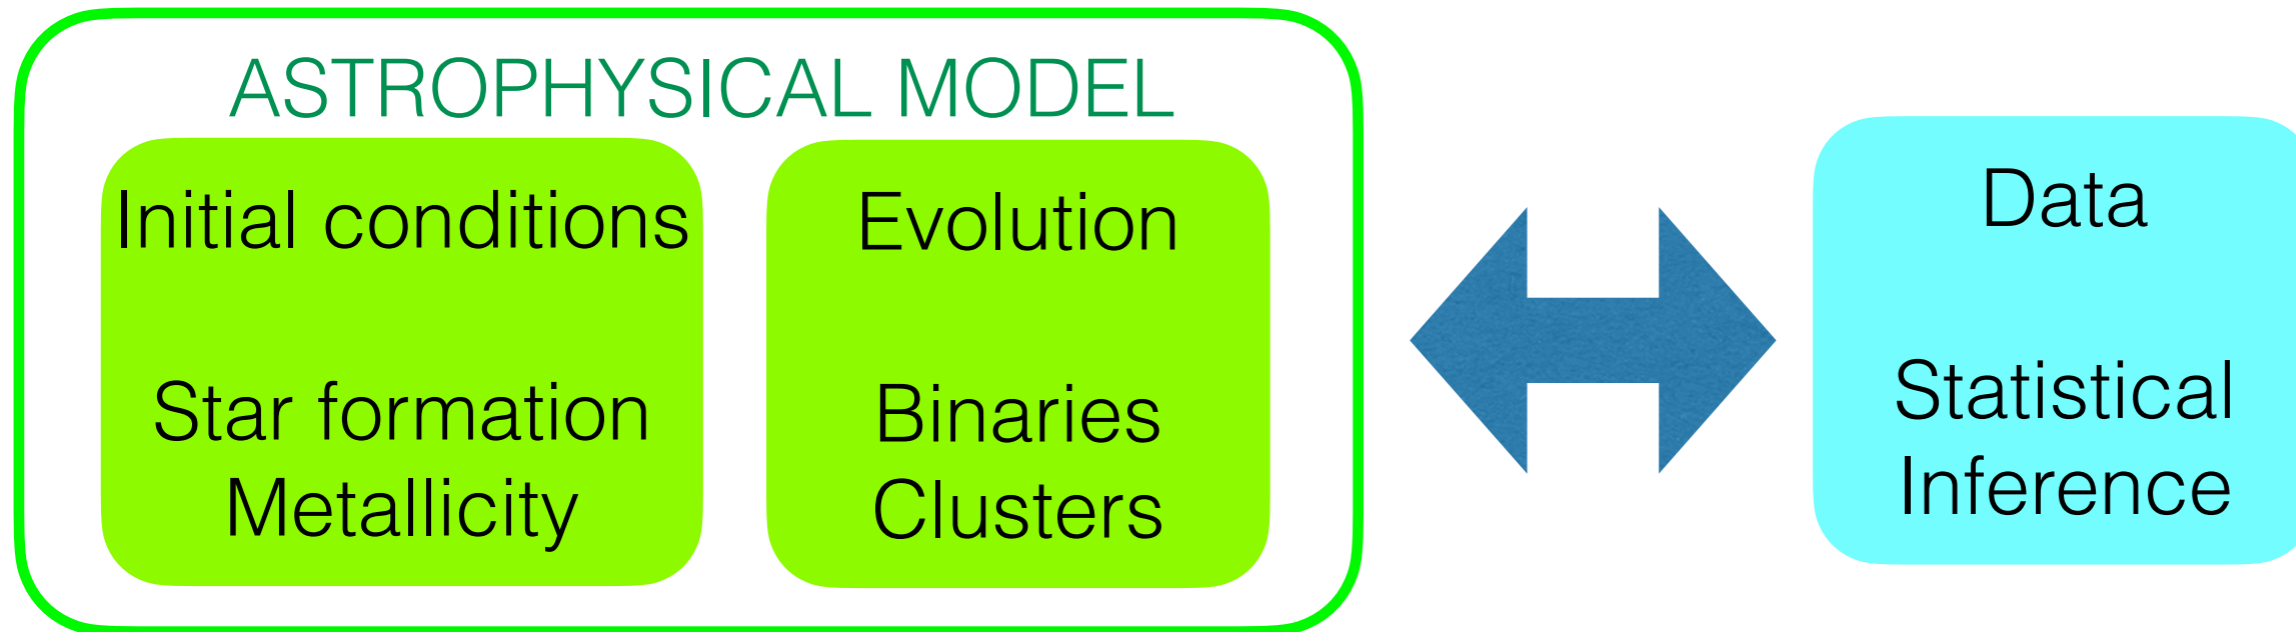

# MODELLING GW POPULATIONS

Models of formation channels should:

- Be consistent (e.g: supernovae & wind physics)
- Account for complex star formation

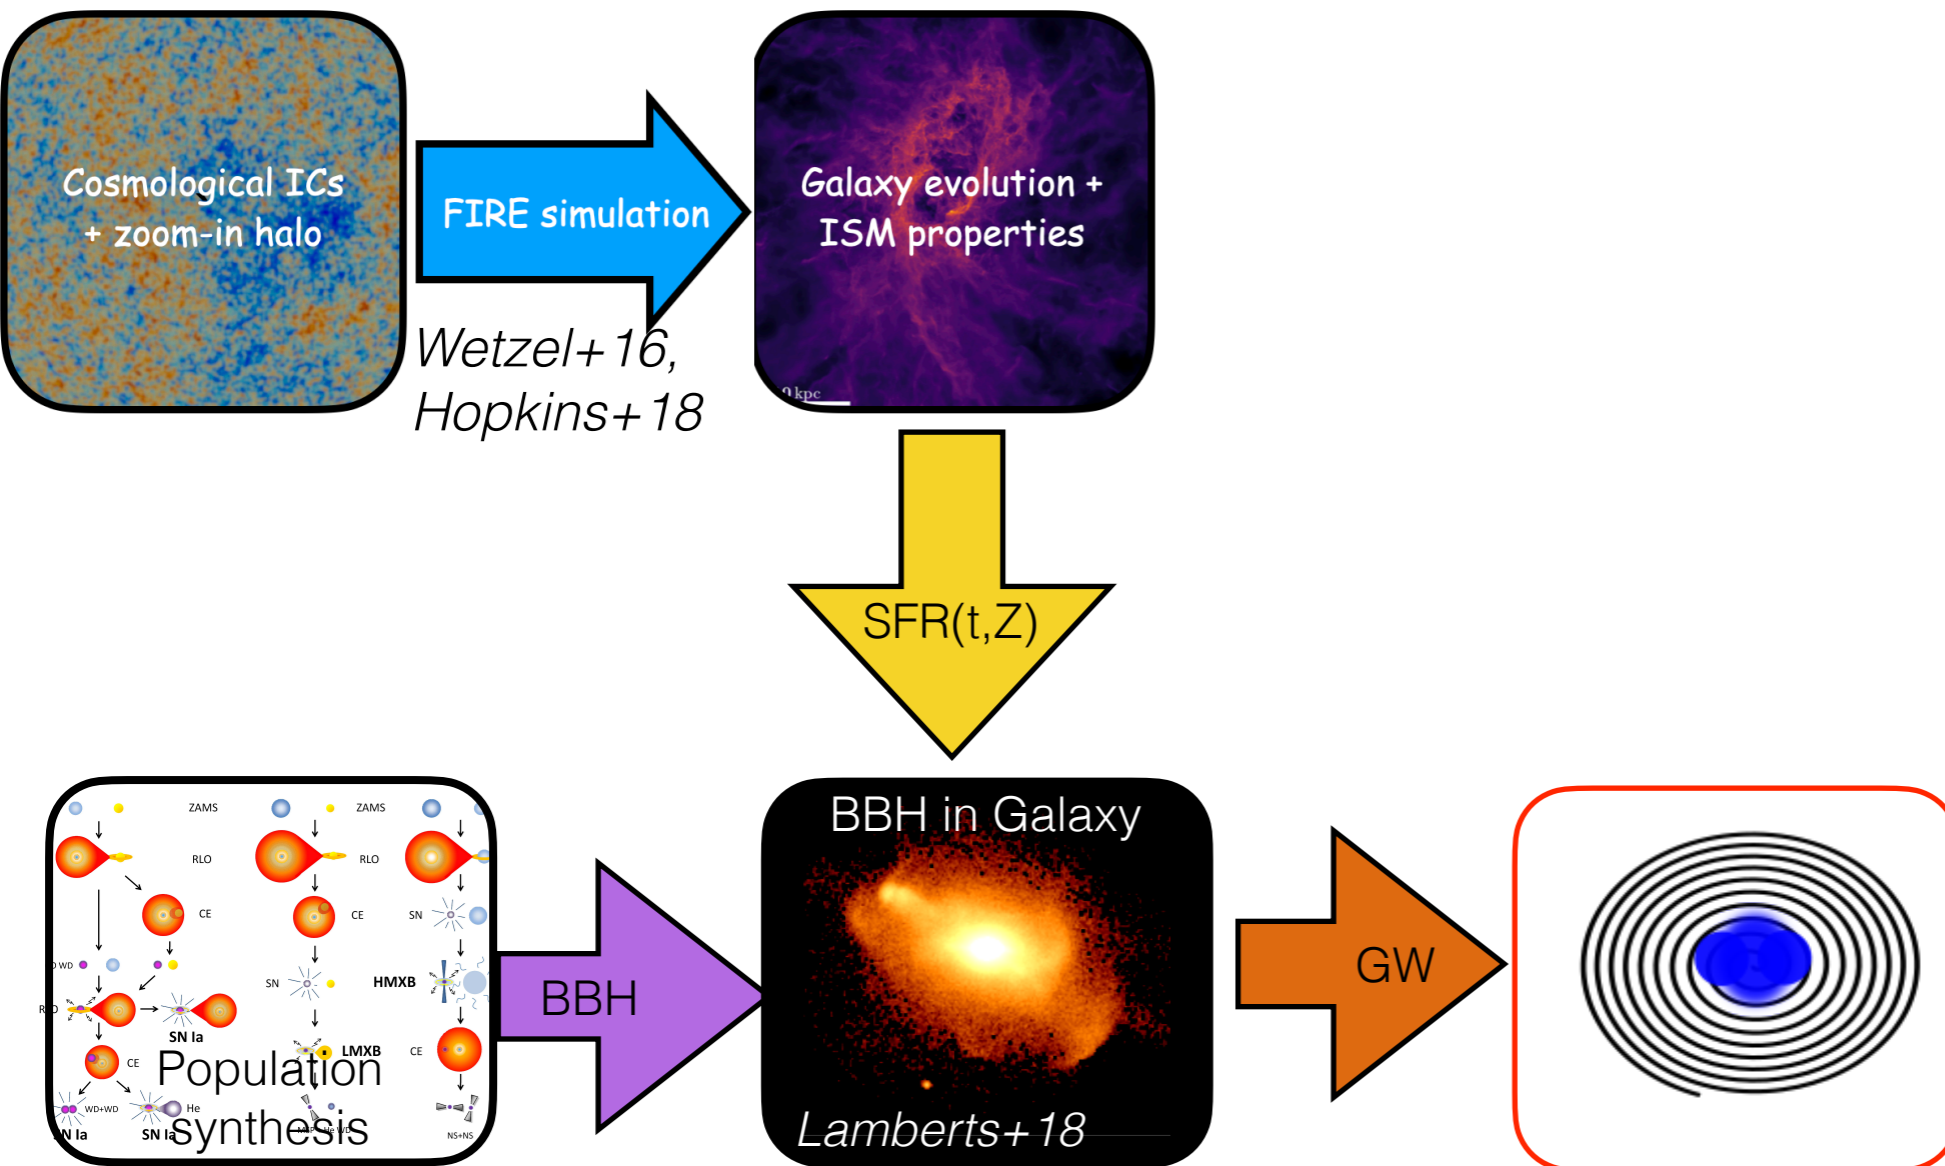

Binary models: ok with star formation models

Cluster models: simple models so far (formation times? Mass profiles? Metallicities?)

**Project goal: improved models to interpret/predict GWs**

# GROWING COMPACT BINARIES IN GALAXIES

# GROWING COMPACT BINARIES IN GALAXIES

*In clusters*

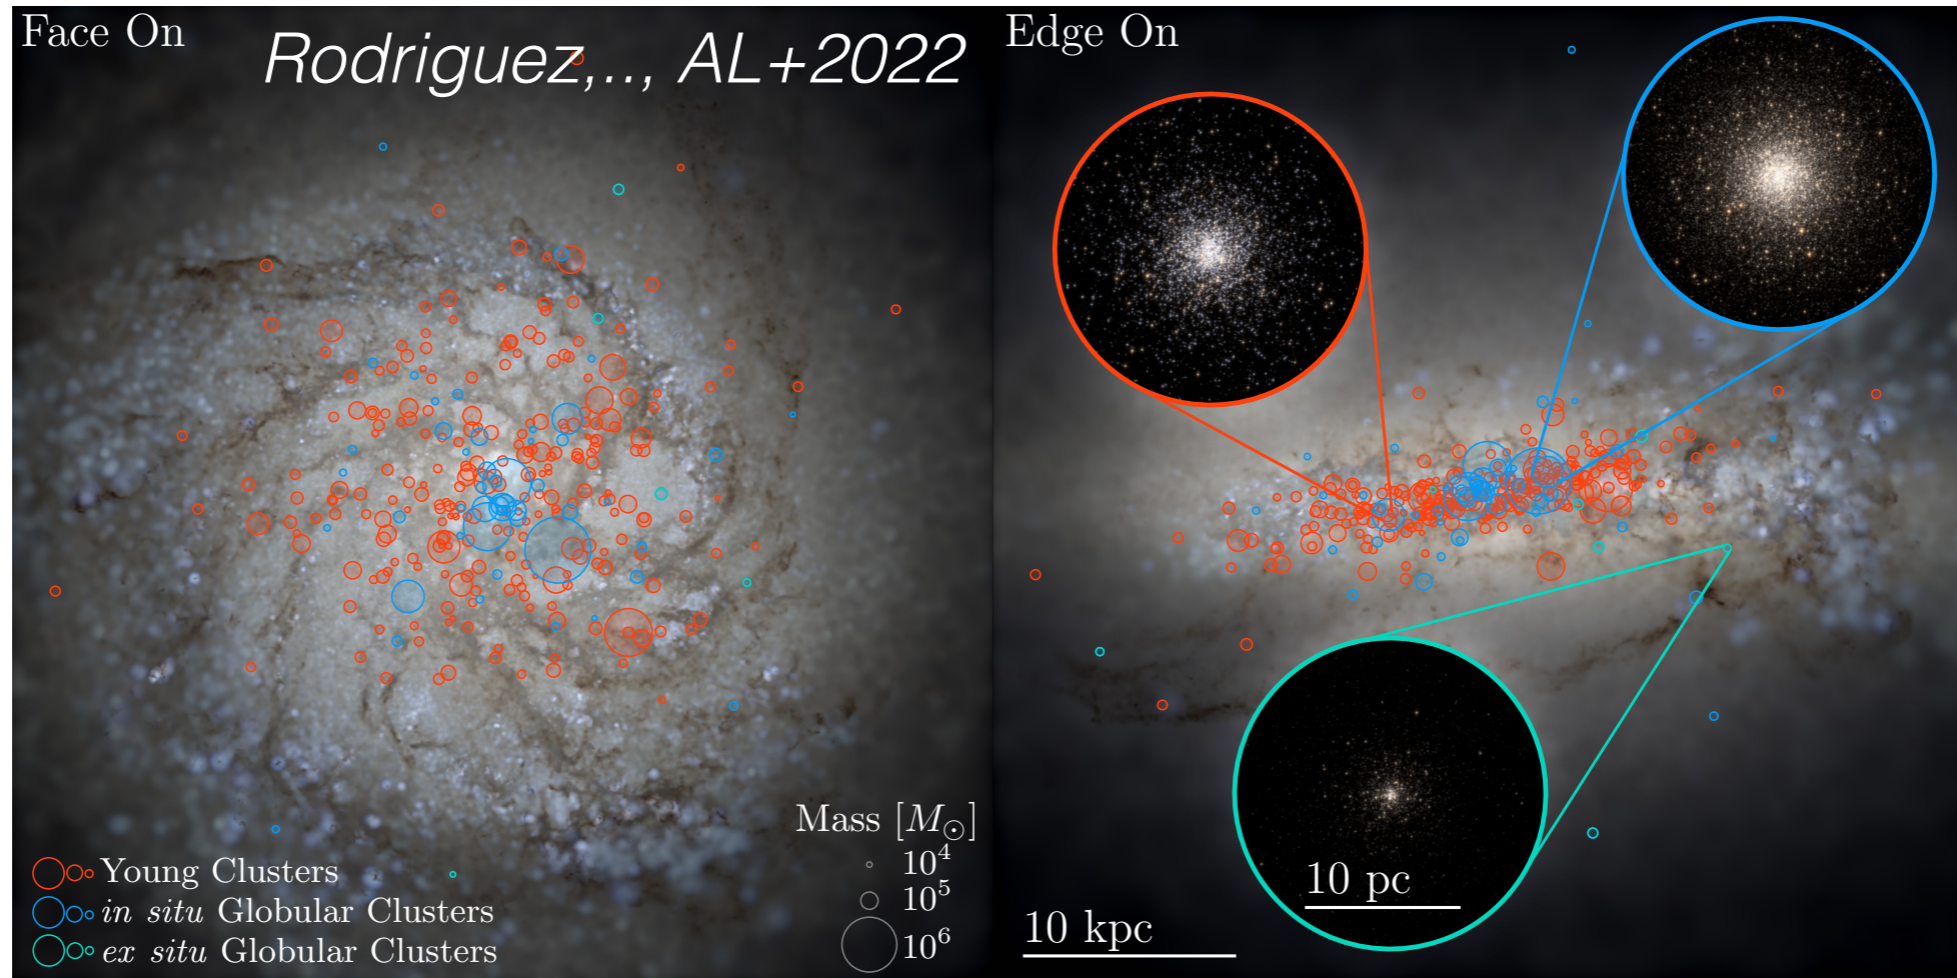

## A first consistent population from binaries and clusters

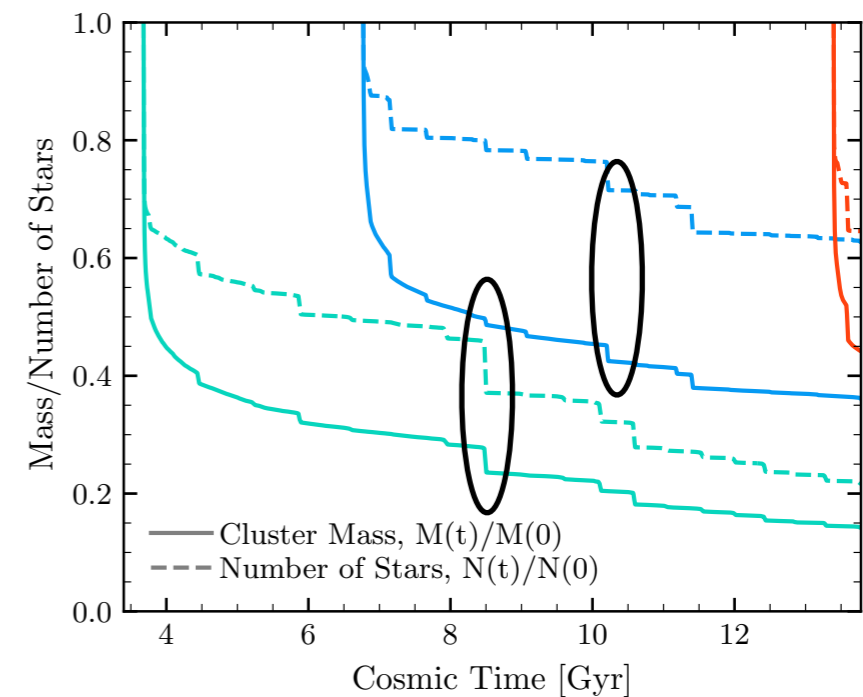

PhD project Tristan Bruel, range of galaxy masses

# CLUSTERS IN A REALISTIC ENVIRONMENT

Tidal forces  $\rightarrow$  disc crossings  $\rightarrow$  stripping  
 $\rightarrow$  more realistic population

# CLUSTERS FROM THE DENSEST CLOUDS

MW-like galaxy

~ LMC

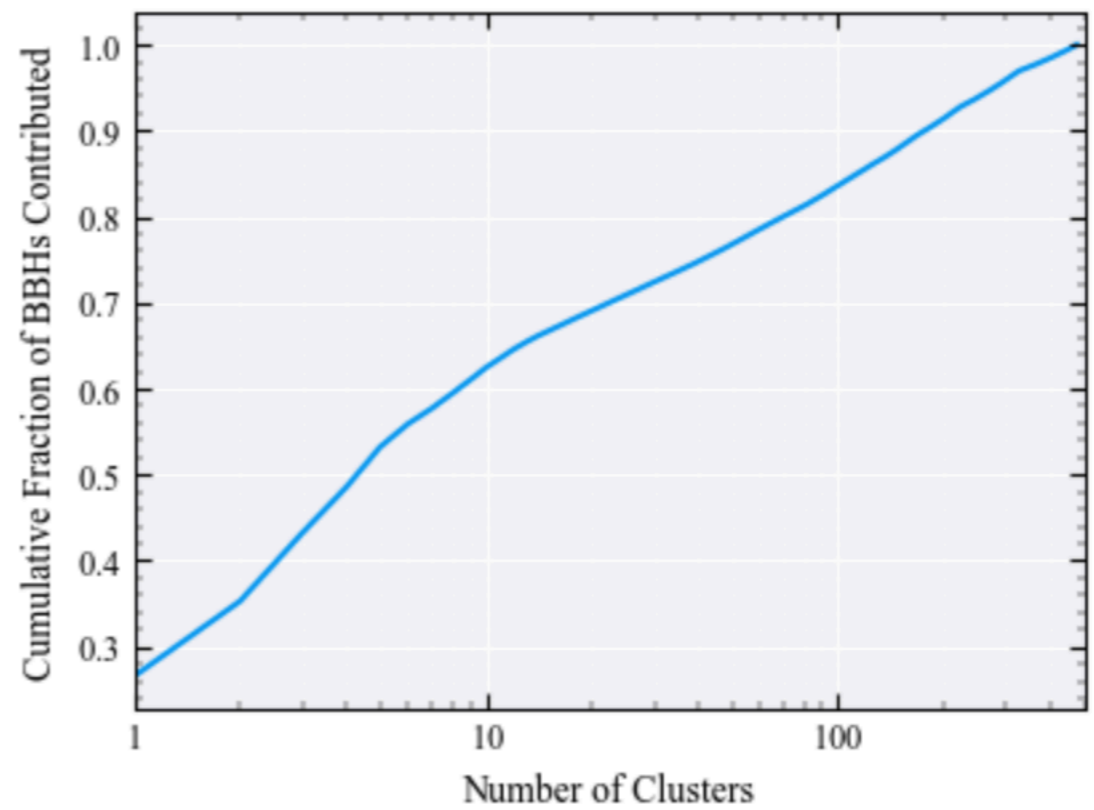

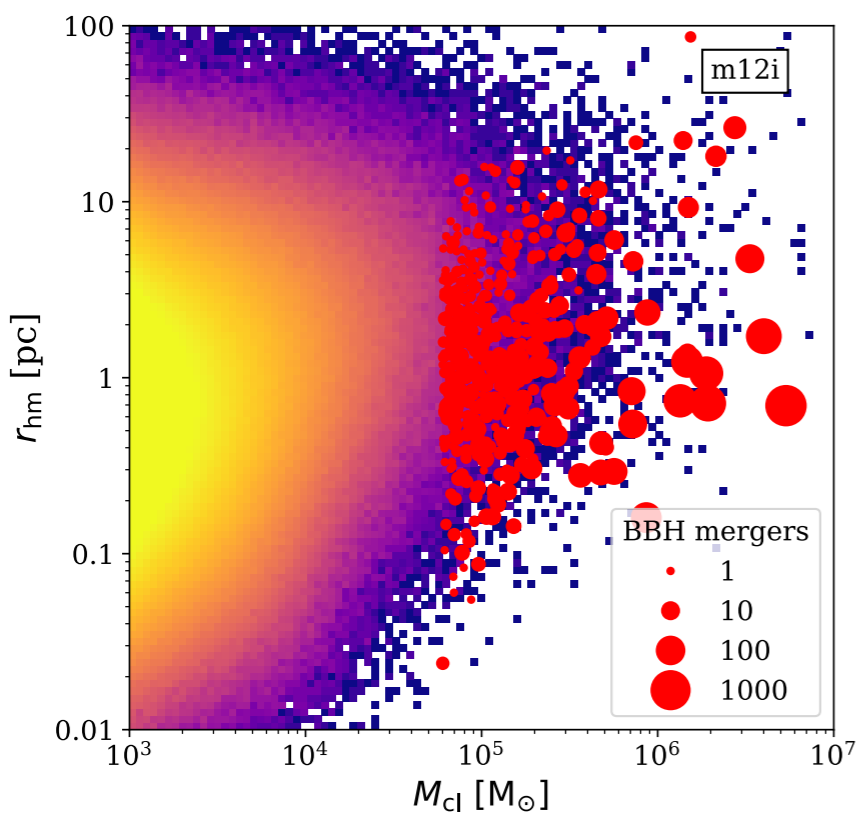

Smaller dwarfs

BBH-forming clusters come from the densest (and most massive) clouds

- > many clusters in massive galaxies
- > important scatter in dwarfs
- > no contribution expected from small dwarfs

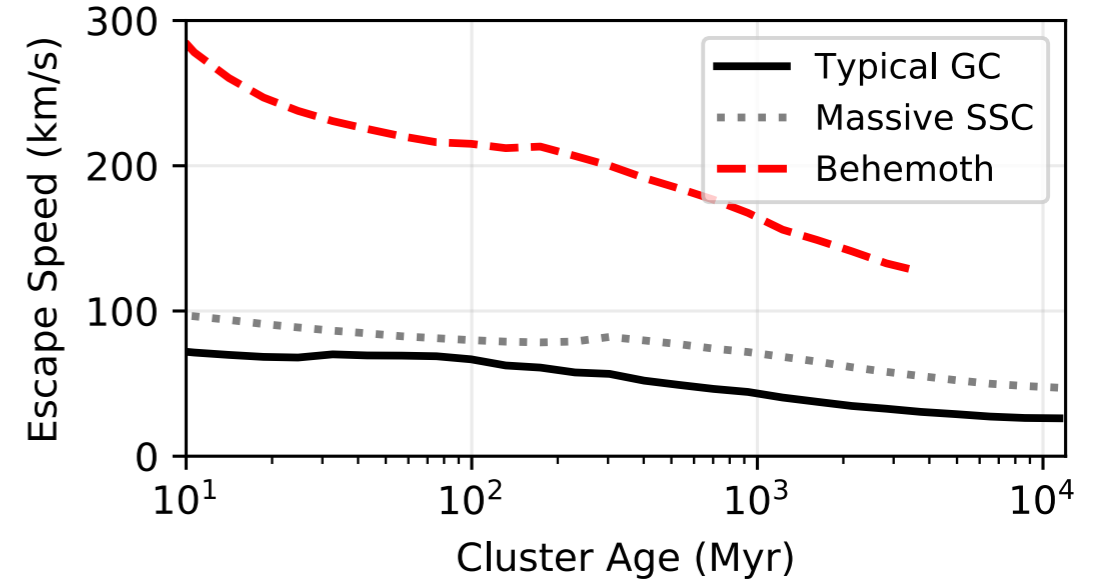

# MERGERS DOMINATED BY MOST MASSIVE CLUSTERS

50% of mergers in 4 clusters

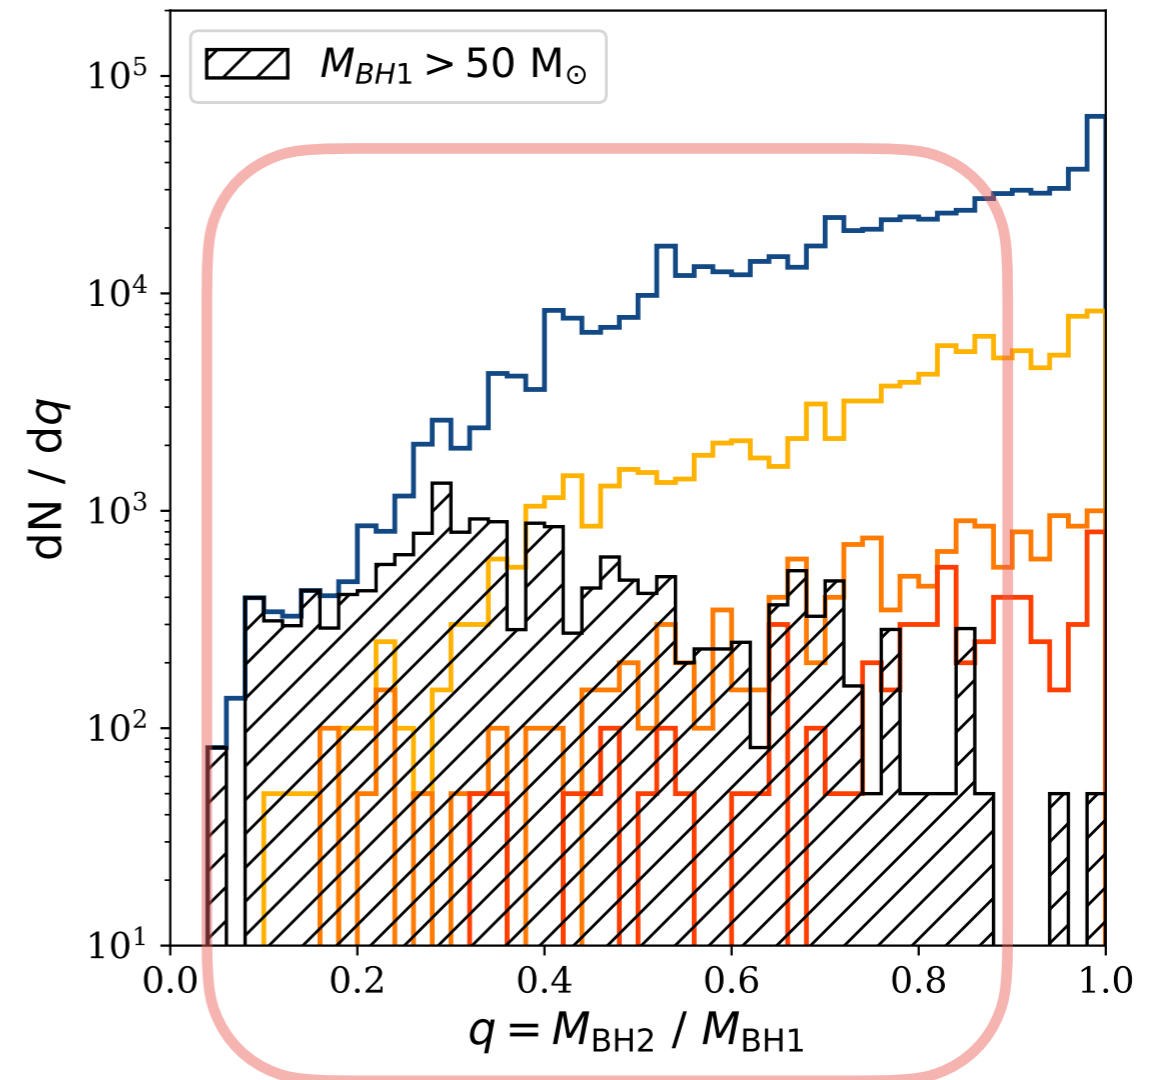

- Correlation with most extreme clouds
- Large escape speed -> several generations
- Not found in « simple » models

(Rodriguez, ..., AL+20)

# MERGING BBHS FROM CLUSTERS

- > formation of massive BBH mergers (not expected in binaries)
- > distribution of wide range of mass ratios
- > several generations in most massive clusters
- > GW190412 (29.7+8.4 Msun): asymmetric merger -> naturally present

# WHERE DO BLACK HOLE MERGERS COME FROM?

GWTC-3  $O(100)$  events

O4 observations ongoing:  $O(300)$  events

Need for **consistent** astrophysical models

Origin of mergers?

Binaries or clusters?

Environment?

Stellar evolution?

First consistent model of BBH mergers in clusters in different types of galaxies (Bruel et al, to be submitted soon)

Diversity of conditions of star formation matters, even more for clusters than binaries

Next? Cosmological merger rates

Connection to galaxy mergers

Stochastic background estimates (w. Irina Dvorkin, thanks PNHE!)

Interpretation of O4 events (postdoc Shanika Galaudage)
