

Cosmology with Dark-Sirens : Hubble constant and black- hole population

Gregoire Pierra

PhD advisor : Stephane Perriès

With the LIGO-Virgo-Kagra collaboration

Current work

Working in the cosmology group of the collaboration :

- Actual project : Understanding the bias on the Hubble constant measurement using gravitational-waves
 - How robust are the methods ?
 - What are the sources of bias ?
- Short author list paper under preparation

Today's talk will present binary black hole spins results

Outline

- **Introduction**
 - Gravitational wave
 - Cosmology
- **Dark sirens**
 - Cosmology with GWs
 - IcaroGW
- **Results**
 - Black hole spins

Gravitational merger

Gravitational-wave physics and astronomy in the 2020s and 2030s

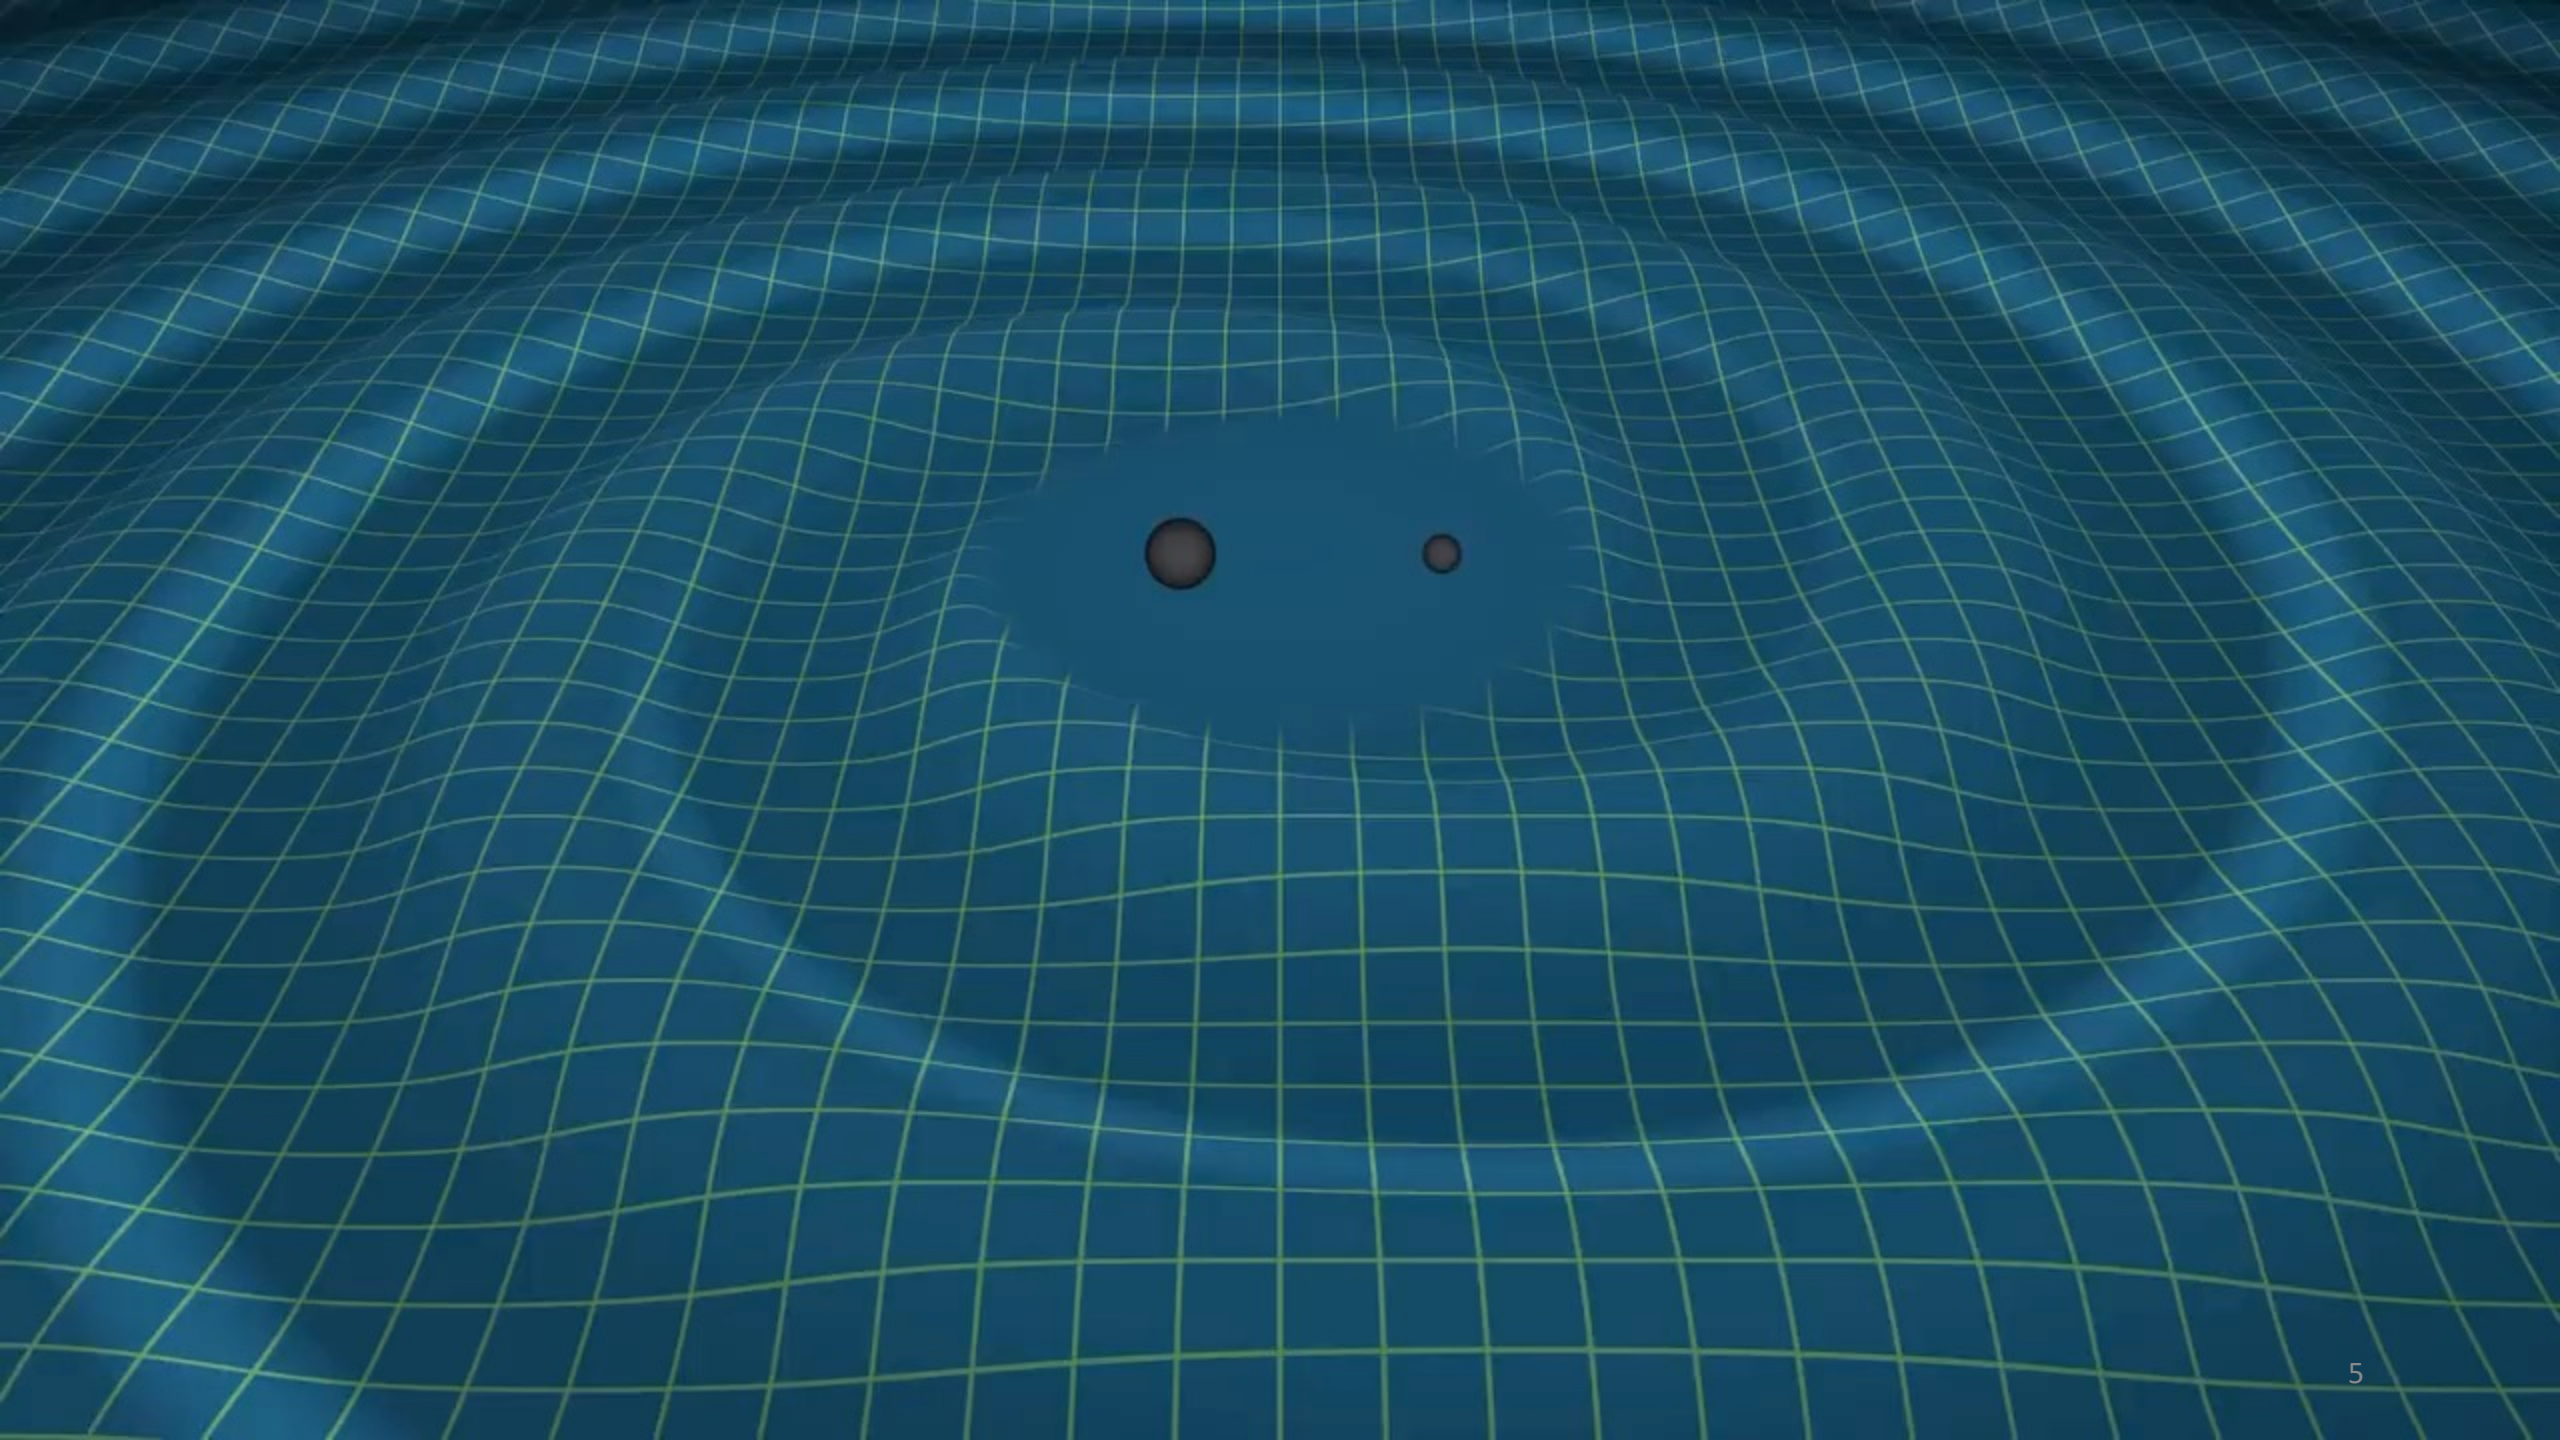

❖ Main source of GWs are compact binary mergers

❖ Merger has 3 phases

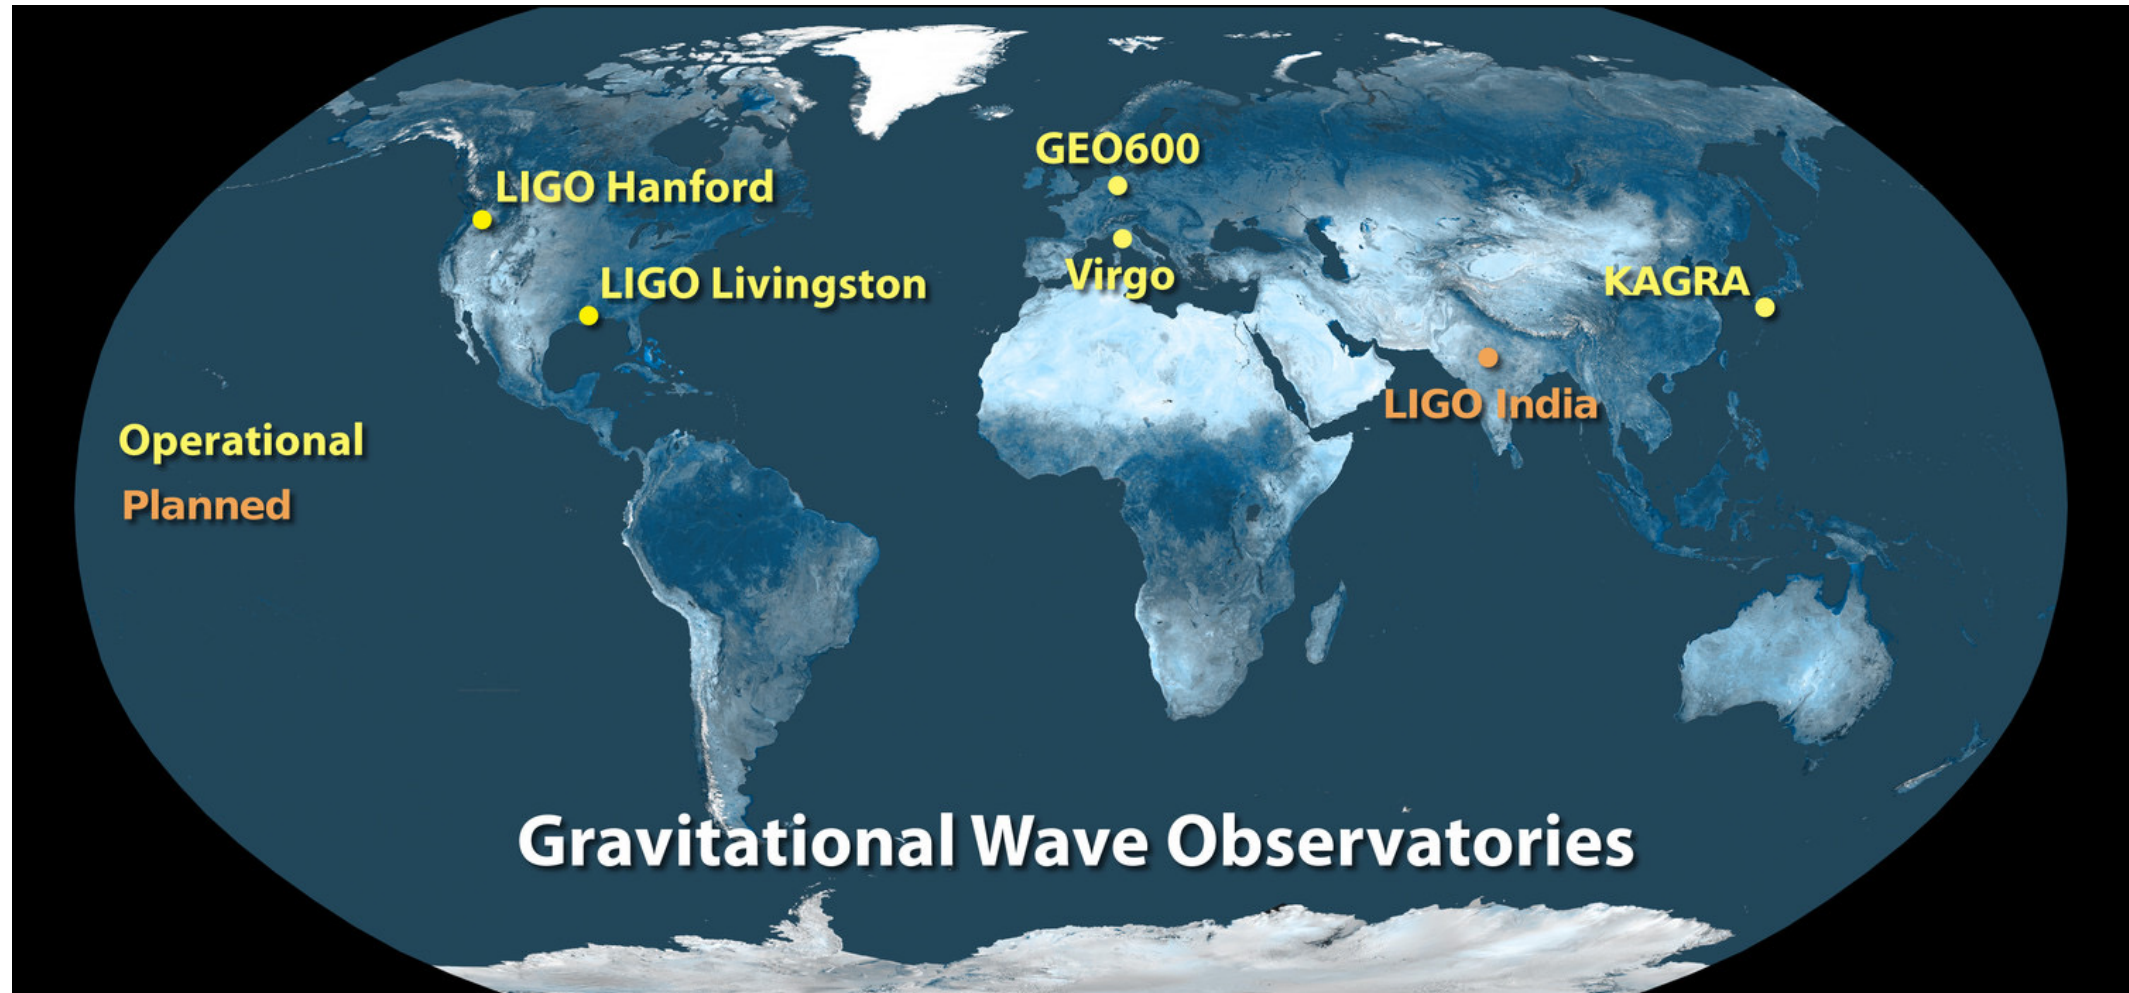

❖ Several properties about the source can be deduced directly from the GW signal :

Luminosity distance d_L Spins of black holes χ

Primary masses of black holes m_1, m_2

Detection of GWs

Detection of GWs

Gr

Observatories

Detection of GWs

The new frontier of gravitational waves

Gws propagates across the Universe at $v = c$ and go through the detector on Earth

The arms will be contracted/extended due to the waves

Change in the light pattern

GW detection

Hubble constant

H_0 = Expansion rate of the universe today
in $km.s^{-1}.Mpc^{-1}$

How fast our universe is expanding

Hubble tension

H_0 = Expansion rate of the universe today
in $km.s^{-1}.Mpc^{-1}$

❖ Two measurements late & early universe :

↙
Supernovae Ia

$$H_0 = 74.03 \pm 1.42$$

Hubble tension

H_0 = Expansion rate of the universe today
in $km.s^{-1}.Mpc^{-1}$

❖ Two measurements late & **early** universe :

↙
Cosmic microwave
background

$$H_0 = 67.4 \pm 0.5$$

Hubble tension

H_0 = Expansion rate of the universe today
in $km.s^{-1}.Mpc^{-1}$

❖ Two measurements late & early universe :

Supernovae Ia

Cosmic microwave
background

$$H_0 = 74.03 \pm 1.42 \quad H_0 = 67.4 \pm 0.5$$

[Dark Energy in light of multi-messenger gravitational-wave astronomy](#)

Hubble tension

H_0 = Expansion rate of the universe today
in $km.s^{-1}.Mpc^{-1}$

❖ Two measurements late & early universe :

Supernovae Ia

Cosmic microwave background

$$H_0 = 74.03 \pm 1.42 \quad H_0 = 67.4 \pm 0.5$$

→ 4.4σ tension

How do we measure H_0 ?

How to access H_0 with GWs ?

- The redshift z and the luminosity distance d_L of a GW source are related through cosmology

$$d_L \simeq \frac{c}{H_0} z$$

(low redshift approximation)

d_L : Directly measurable
the GW signal

z : Need to be found through
other methods

- Access H_0 by breaking this degeneracy

GW170817 : golden event

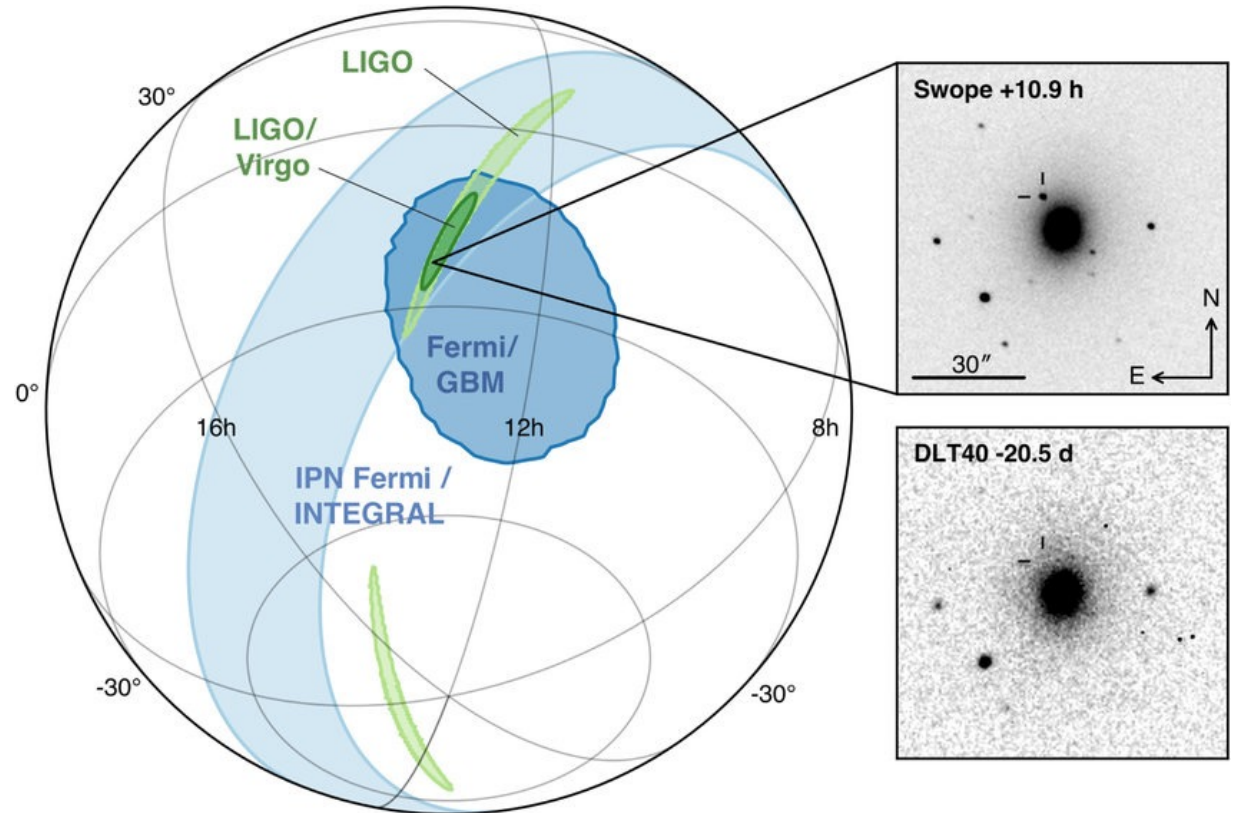

GW170817 is a **binary neutron stars** event

Two type of signals were emitted :

$$H_0 = 70.0^{+12.0}_{-8.0} \text{ km.s}^{-1} . \text{Mpc}^{-1}$$

But still in agreement with the early and late universe values...

GWs state of the art

Since 2015, LIGO and Virgo had 3 observation runs

❖ 90 Compact binary mergers

❖ 89 of them are Dark-Sirens
(no E.M. counterpart)

Note that the mass estimator program here does not include uncertainties, which is why the final mass is sometimes larger than the sum of the primary and secondary masses. In reality, the final mass is smaller than the sum of the primary and secondary masses.
The events listed here pass one of two thresholds for detection. They either have a probability of being astrophysical of at least 50%, or they pass a false alarm rate threshold of less than 1 per 3 years.

GRAVITATIONAL WAVE
MERGER
DETECTIONS

Outline

- **Introduction**
 - Gravitational wave
 - Cosmology
- **Dark sirens**
 - Cosmology with GWs
 - IcaroGW
 - Black hole spins
- **Results**

Dark-Sirens method

- ❖ GWs are redshifted due to cosmological expansion

- ❖ Degeneracy between the detected and the source mass of BBH : $m_i^{\text{det}} = (1 + z)m_i^{\text{source}}$

Dark-Sirens method

ICAROGW : Inferring Cosmology and AstRophysics with Observations of Gravitational Waves

- One of the two official pipelines in LVK for cosmology analysis.
(main dev : S. Mastrogiovanni, G. Pierra et al.)
- **Jointly** infer the **population** parameters (masses, redshift, rate, **spins**) and the **cosmological** parameters (H_0 , Ω_m , w_0)
- Hierarchical Bayesian inference method with **Dark-Sirens** events (no e.m. counterpart)
- Based on the mass-redshift degeneracy : $m_i^{\text{det}} = (1 + z)m_i^{\text{source}}$

Dark-Sirens method

❖ By fixing the cosmology :

→ Deduce the true mass distribution of BBH

$$m_i^d = (1 + z) m_i^s$$

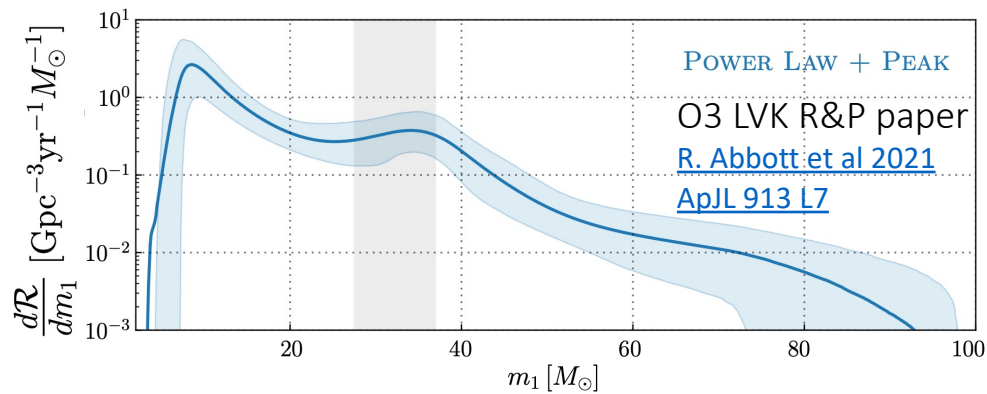

Dark-Sirens method

❖ By fixing the cosmology :

→ Deduce the true mass distribution of BBH

$$m_i^d = (1 + z) m_i^s$$

❖ By fixing the population :

→ Deduce the cosmology

$$m_i^d = (1 + z) m_i^s$$

O3 LVK Cosmology paper
[arXiv:2111.03604](https://arxiv.org/abs/2111.03604)

Best measure so far

Combined with GW1708187 :

$$H_0 = 68_{-6}^{+8} \text{ km.s}^{-1}.\text{Mpc}^{-1}$$

- **Results**

Inclusion of BBH spins for cosmology

Aim : Add BBH spin distributions to generalize the analysis :

❖ Development of two spin models for BBH

Default spin model : First introduced by LSC collaboration [arXiv:1811.12940](https://arxiv.org/abs/1811.12940)

Gaussian spin model : First introduced by Schmidt et al. [arXiv:1408.1810](https://arxiv.org/abs/1408.1810)

Motivations

- ❖ Generalize the analysis and be ready for future spins measurement
- ❖ Spins could correlate with the Hubble constant H_0
- ❖ BBH formation channels might prefer specific spin configurations

Impact of the spins

Number of orbits is impacted by the spin orientation of each BHs

→ Direct effect on the amplitude of the GWs

Impact of the spins

Modulation of the GW signal due to spin effect

→ Direct effect on the envelope of the GWs

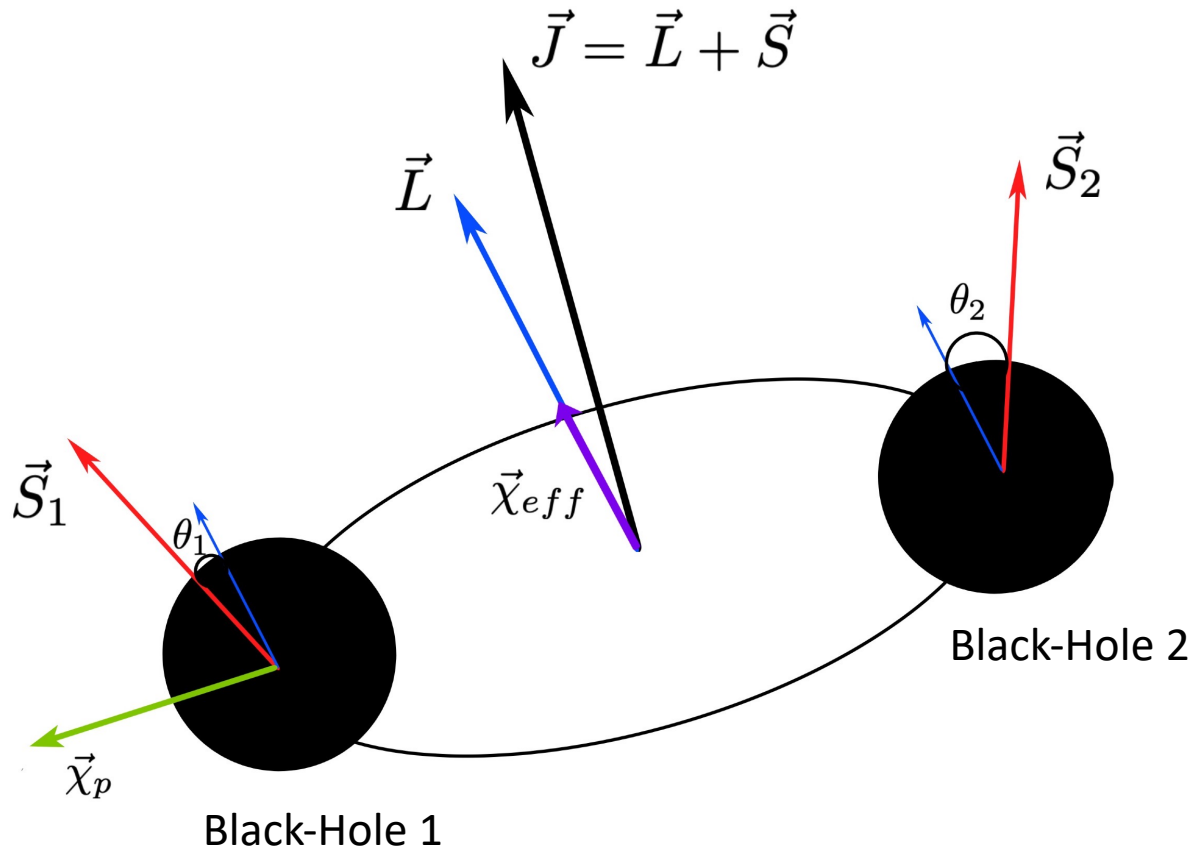

Spin models of BBH

Default spin model

- ❖ Multiple formation channels
- ❖ Covers all 6 degrees of freedom

Gaussian spin model

- ❖ Sensitive to precession effects
- ❖ Sensitive to spin asymmetries

Outline

- **Introduction**
 - Gravitational wave
 - Cosmology
- **Dark sirens**
 - Cosmology with GWs
 - IcaroGW
- **Results**
 - Black hole spins

Set-up of the analysis

- ❖ **First time analysis** that jointly estimates the cosmology and spins parameters of black-holes !
- ❖ These results have been obtain using **42 BBHs events** from the O3 run of LVK
- ❖ We tested **both spin models**

Default model

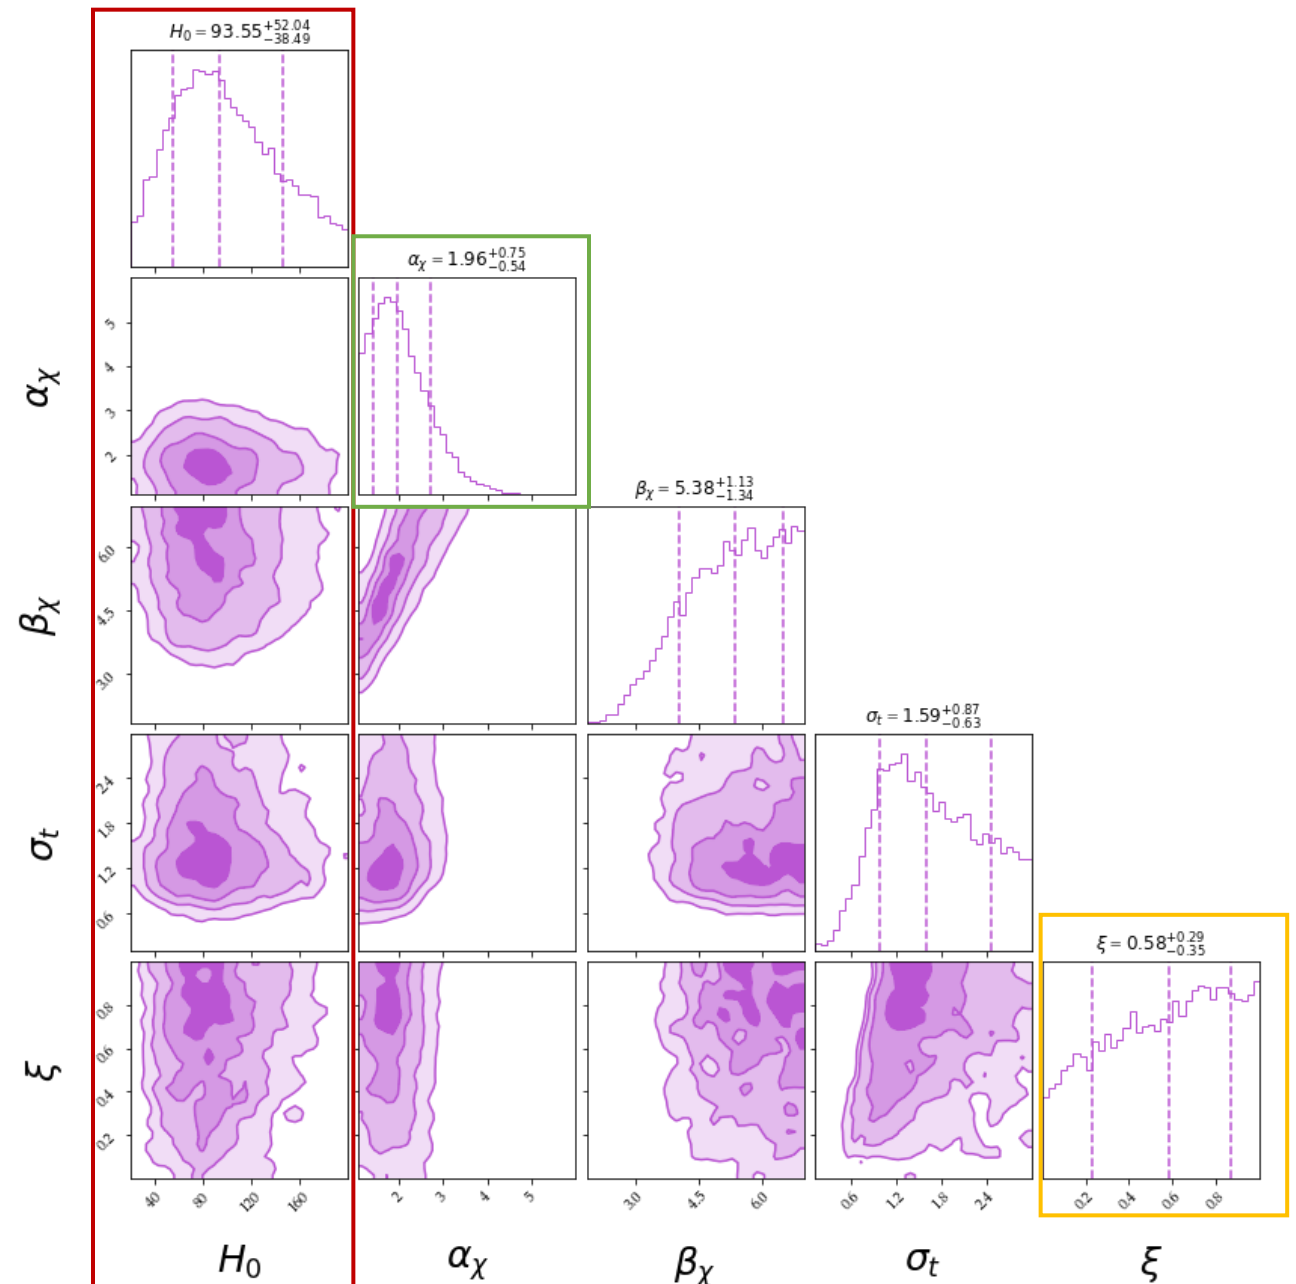

$$\pi(\chi_{1,2}|\alpha_\chi, \beta_\chi) = \text{Beta}(\alpha_\chi, \beta_\chi)$$

$$\pi(\cos\theta|\zeta, \sigma_t) = \zeta G_t(\cos\theta|\sigma_t) + (1 - \zeta)\mathcal{F}(\cos\theta)$$

❖ No spin correlation with H_0 so far

❖ Preference for a slowly spinning black-hole population

❖ Mixed population between isolated and dynamical mergers

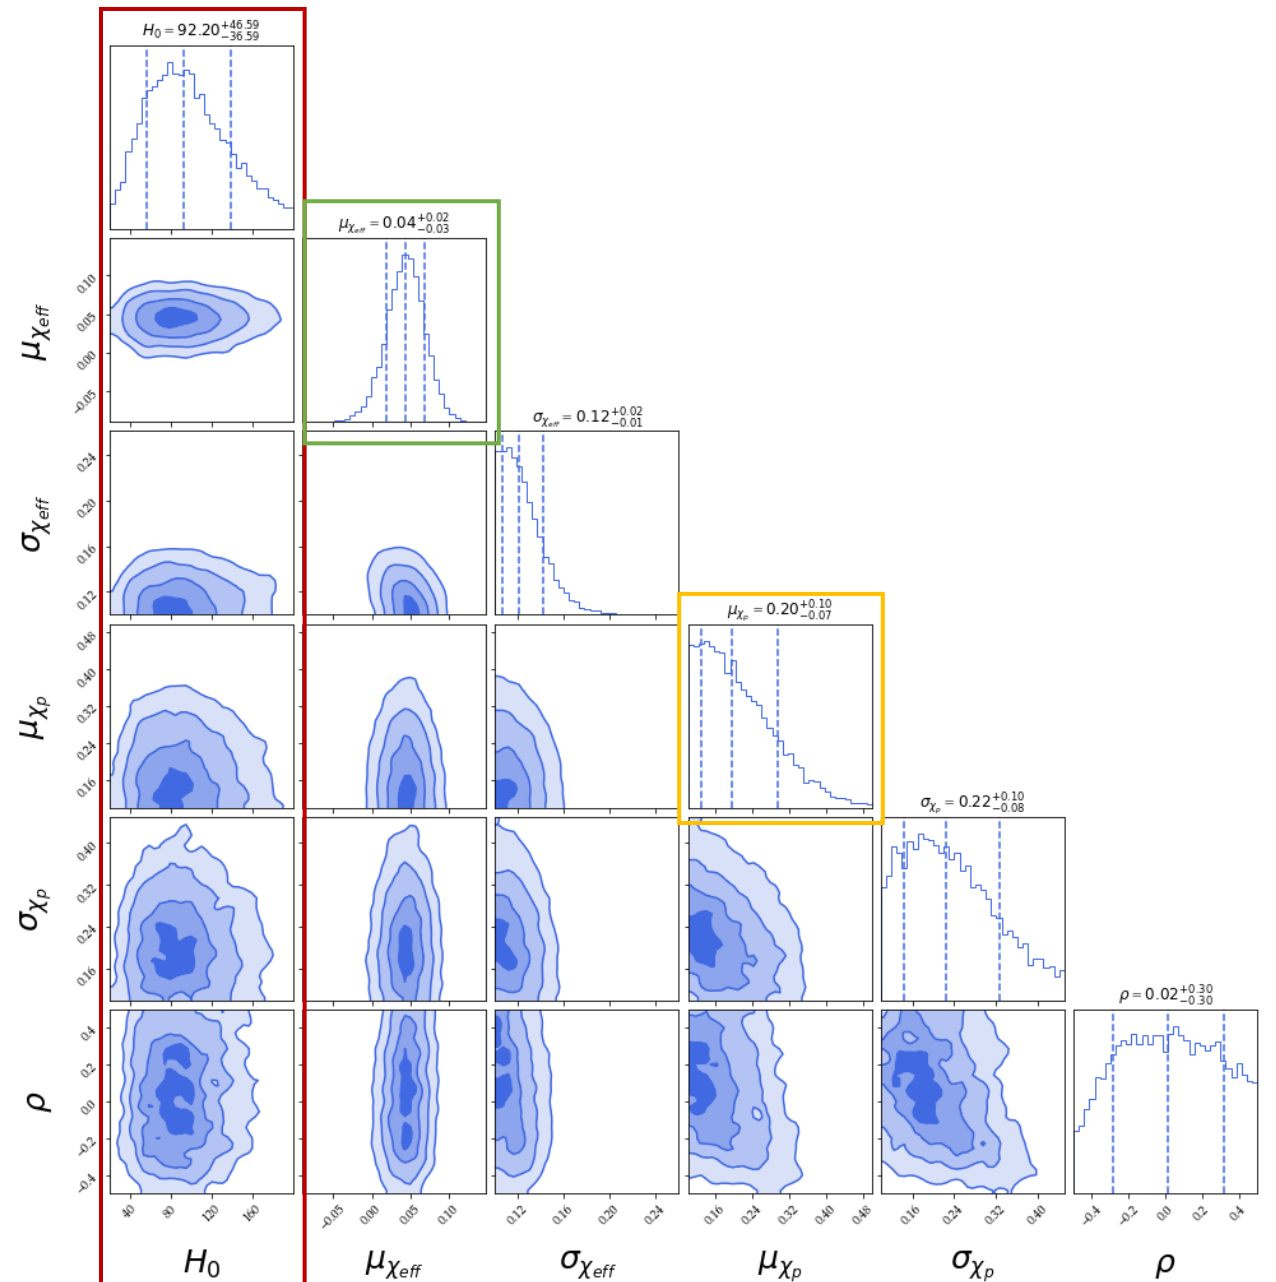

Gaussian model

$$\pi(\chi_{eff}, \chi_p | \mu_{eff}, \sigma_{eff}, \mu_p, \sigma_p) = G_{[-1,1],[0,1]}^{2D}(\chi_{eff}, \chi_p | \mu, \Sigma)$$

❖ No spin correlation with H_0

❖ Aligned spins are favoured

❖ Slowly precessing black-holes

Conclusion on spins

- Correlation BBH spins/cosmology not yet found
- Spin properties on the population of BBH :
 - Slowly spinning
 - No preferred channel of formation (isolated/dynamical)
 - Slowly precessing
 - Mostly aligned
- Current sensitivity too low to explore spin effects on GW signals

Perspectives

- Next run of LVK starting on 24th of may 2023 (hundreds of GWs events)
- IcaroGW2.0 with spins is officially reviewed
- IcaroGW will be used as one of the two cosmology codes in the LVK collaboration for the next observation run
- Constraints on cosmology and population parameters will get better and better with higher statistic

Thanks

BACK UP

Basic principle behind IcaroGW

❖ Infer **jointly** the population and cosmological parameters via **hierarchical** Bayesian inference :

$$p(\text{cosmology}|\text{GWs}) \propto \prod_i^{N_{\text{obs}}} \frac{\int p(\text{GW}_i|\theta, \Lambda)\pi(\theta|\Lambda)d\theta}{N_{\text{eff}}}$$

Probability of estimating a certain cosmology
given some GWs data

Galaxy catalog results

From the galaxy catalog only :

$$H_0 = 67_{-12}^{+13} \text{ km.s}^{-1}.\text{Mpc}^{-1}$$

Combined with GW1708187 :

$$H_0 = 68_{-6}^{+8} \text{ km.s}^{-1}.\text{Mpc}^{-1}$$

Back up

$$d_L(z) = \frac{1+z}{H_0} c \int_0^z \frac{dz}{(\Omega_m(1+z)^3 + \Omega_\Lambda)} \quad \text{and} \quad z = \frac{m^d}{m^s} - 1$$

Spin models of BBH

Default spin model

$$\chi_i = \left| \frac{\vec{S}_i}{m_i^2} \right|$$

Dimensionless spin magnitudes & tilt angle :

$$\pi(\chi_{1,2} | \alpha_\chi, \beta_\chi) = \text{Beta}(\alpha_\chi, \beta_\chi)$$

$$\pi(\cos\theta | \zeta, \sigma_t) = \zeta G_t(\cos\theta | \sigma_t) + (1 - \zeta) \mathcal{F}(\cos\theta)$$

Gaussian spin model

Effective & precession spin :

$$\pi(\chi_{eff}, \chi_p | \mu_{eff}, \sigma_{eff}, \mu_p, \sigma_p) = G_{[-1,1],[0,1]}^{2D}(\chi_{eff}, \chi_p | \mu, \Sigma)$$

$$\vec{\mu} = (\mu_{eff}, \mu_p)$$

$$\Sigma = \begin{pmatrix} \sigma_{eff}^2 & \rho \sigma_{eff} \sigma_p \\ \rho \sigma_{eff} \sigma_p & \sigma_p^2 \end{pmatrix}$$

Spin distributions : Default

(a)

(b)

(a) and (c) :
Joint 2D probability density functions

(b) and (d) :
Marginalized probability density functions

$$\{\alpha = 2.6, \beta = 6.6, \zeta = 0.76, \sigma_t = 0.87\}$$

(c)

(d)

Described black-holes :

- Slowly rotating
- Mostly aligned with \vec{L}

Spin distributions : Gaussian

$$\{\mu_{eff} = 0.11, \sigma_{eff} = -0.18, \mu_p = 0.31, \sigma_p = 0.29, \rho = 0.32\}$$

(a)

(b)

❖ (a) :
Joint 2D probability density functions

❖ (b) :
Marginalized probability density functions

Described black-holes :

- Slight asymmetry toward aligned spins
- Slowly precessing systems
