#### Quantum patents

An analysis of global patents in quantum technology since 2012 shows China dominating quantum communication, but North America ahead on quantum computing.

#### Measurement

Quantum bit  $\partial \left| 0 \right\rangle + \left| b \right|^2 + \left| b \right|^2 = 1$ 

#### Measurement:

- Probability  $|a|^2$  to measure the qubit in the state  $|0\rangle$  $\Rightarrow$  After measurement qubit state =  $|0\rangle$
- Probability  $|b|^2$  to measure the qubit in the state  $|1\rangle$ => After measurement qubit state =  $|1\rangle$

Entangled state for two particules A and B

$$\frac{\left|0_{A},0_{B}\right\rangle + \left|1_{A},1_{B}\right\rangle}{\sqrt{2}}$$

If A is measured in state 0, then B is in state 0 If A is measured in state 1, then B is in state 1

**Abstract.** A digital computer is generally believed to be an efficient universal computing device; that is, it is believed able to simulate any physical computing device with an increase in computation time by at most a polynomial factor. This may not be true when quantum mechanics is taken into consideration. This paper considers factoring integers and finding discrete logarithms, two problems which are generally thought to be hard on a classical computer and which have been used as the basis of several proposed cryptosystems. Efficient randomized algorithms are given for these two problems on a hypothetical quantum computer. These algorithms take a number of steps polynomial in the input size, e.g., the number of digits of the integer to be factored.

Figure 3: False-coloured image of an 8-qubit superconducting quantum processor fabricated at ETH Zurich. All eight qubits (red) are measured using a common readout line (yellow), by coupling each qubit (red) to a pair of readout resonator (cyan) and Purcell filter (green). Qubit control is enabled by individual charge lines (purple) and flux lines (blue). Coupling between nearest neighbour qubits is mediated by bus resonators (orange).

# Two quantum bit gates ?? (the great challenge)

# A scheme for efficient quantum computation with linear optics

\* Los Alamos National Laboratory, MS B265, Los Alamos, New Mexico 87545, USA † Centre for Quantum Computer Technology, University of Queensland, St. Lucia, Australia

Quantum computers promise to increase greatly the efficiency of solving problems such as factoring large integers, combinatorial optimization and quantum physics simulation. One of the greatest challenges now is to implement the basic quantum-computational elements in a physical system and to demonstrate that they can be reliably and scalably controlled. One of the earliest proposals for quantum computation is based on implementing a quantum bit with two optical modes containing one photon. The proposal is appealing because of the ease with which photon interference can be observed. Until now, it suffered from the requirement for non-linear couplings between optical modes containing few photons. Here we show that efficient quantum computation is possible using only beam splitters, phase shifters, single photon sources and photo-detectors. Our methods exploit feedback from photo-detectors and are robust against errors from photon loss and detector inefficiency. The basic elements are accessible to experimental investigation with current technology.

#### 2-mode Grover's search algorithm

We implement in this notebook a 2-mode optical realization of Grover's search algorithm following *Kwiat et al.* (2000). Grover's search algorithm: An optical approach. Journal of Modern Optics, 47(2-3), 257–266. https://doi.org/10.1080/09500340008244040

#### Motivation

Searching for a specific item in an unstructured list of N items will classically necessitate  $\mathcal{O}(N)$  function calls. Grover showed in 1996 that is possible for a quantum computer to achieve this using only  $\mathcal{O}(\sqrt{N})$  iterations.

#### Algorithm breakdown

Suppose we are implementing Grover's algorithm with *NN* qubits. The algorithm's first part consists in setting each of these qubits in a quantum superposition  $\frac{|0>+|1>}{m^{-2}}$ . Then, a so-called oracle is applied on the qubits.
