## Measurement of azimuthal anisotropy at high $p_T$ using subevent cumulants in pPb collisions at CMS

*mardi 4 juin 2024 18:59 (1 minute)*

Measurements at the LHC have provided evidence for collective behavior in high-multiplicity proton-proton (pp) and proton-lead (pPb) collisions through multiparticle correlation techniques. To investigate detailed properties of this collectivity, a comprehensive study of differential Fourier coefficients ( $v_n$ ) in particle transverse momentum ( $p_T$ ) and event multiplicity is presented in pPb collisions recorded by the CMS experiment at a nucleon-nucleon center-of-mass energy  $\sqrt{s_{NN}} = 8.16$  TeV. In particular, new measurements of  $p_T$ -differential multiparticle cumulants using the subevent cumulant method in distinct subevent regions are presented. Relative to past CMS measurements, the new study probes an extended phase space region up to a high particle  $p_T$ , putting the observation of nonzero high- $p_T$   $v_2$  in a small-sized medium into stringent tests.
