

# Recent experimental results in UPC collisions on incoherent and dissociative production with ALICE

Michael Winn

Department of Nuclear Physics IRFU/CEA, university Paris-Saclay

GDR workshop, 12.10.2023

**Gluo***ynamics*

# Outline

- ▶ Motivation
- ▶ proton-lead (pPb): proof-of-principle for proton dissociation at the LHC  
[arxiv:2304.12403](https://arxiv.org/abs/2304.12403), submitted to PRD
- ▶ lead-lead (PbPb): illustration of coherent and incoherent separation with t-dependent measurements
- ▶ Discussion of limitations
- ▶ Perspectives, conclusions  
→ focus on motivation and on current methods

# Motivation

- ▶ background for exclusive vector-meson production, see presentation by Ronan
- ▶ Motivation on its own for incoherent/dissociative production

Focus on heavy quarkonium: hard scale via mass;

focus on  $\gamma^{(*)}p$ ,

short recap on  $\gamma^*Pb \rightarrow J/\psi X$

focus on ALICE, STAR preliminary results discussed by Daniel yesterday

# Exclusive vector meson production in ultra-peripheral collisions

- ▶ sensitive to generalised gluon distributions (GPD) for  $x \in 10^{-2} - 10^{-6}$
- ▶ measurements for protons and nuclei
- ▶ exclusive photoproduction at small  $t \approx$  interaction with full wavepackage of target hadron  
→ coherent interaction
- ▶ see presentations of Ronan, Mallick, Daniel

# Coherent production: measuring the 'average' size

$$\text{coherent} : \frac{d\sigma^{\gamma^* p \rightarrow p J/\psi}}{dt} = \frac{1}{16\pi} |\langle \mathcal{A}^{\gamma^* p \rightarrow p J/\psi} \rangle|^2$$

p: proton (also valid for nuclei),  $J/\psi$  could be any vector, e.g. in H. Mäntisaary [Rep. Prog. Phys. 83 \(2020\)](#).

- ▶ Good-Walker formalism [PRD 120 \(1960\)](#)
- ▶ average over interactions of states that make up the incoming particle and diagonalise the interaction matrix
- ▶ high energy: Fock states of the incoming virtual photon with frozen number of partons and frozen configuration of the target  
→ GPDs single-particle distributions, see in [Z. Panjsheeri](#)

# Incoherent production: measure fluctuations

incoherent case: incoming ( $|i\rangle$ ) and outgoing state ( $|f\rangle$ ) different

$$\begin{aligned} \text{use : } \sum_{f \neq i} |\langle f|A|i\rangle|^2 &= \sum_f \langle i|A^*|f\rangle \langle f|A|i\rangle - \langle i|A|i\rangle \langle i|A^*|i\rangle \\ &= \langle i|A^*A|i\rangle - |\langle i|A|i\rangle|^2 \end{aligned}$$

average over  $i$  :

$$\frac{d\sigma^{\gamma^* p \rightarrow p^* J/\psi}}{dt} = \frac{1}{16\pi} \left( \langle |\mathcal{A}^{\gamma^* p \rightarrow p J/\psi}|^2 \rangle - |\langle \mathcal{A}^{\gamma^* p \rightarrow p J/\psi} \rangle|^2 \right)$$

$p$ : proton (also valid for nuclei),  $p^*$  proton excited,  $J/\psi$  could be any vector, recent review in H. Mäntisaari [Rep. Prog. Phys. 83 \(2020\)](#), so-called 'Good-Walker' formalism, also in Frankfurt, Strikman, Treleani, Weiss [PRL 101 \(2008\) 202003](#).

→ incoherent: variance  $\langle x^2 \rangle - \langle x \rangle^2$ , not average  $\langle x \rangle^2$

- ▶  $\gamma p$ : dissociative production → fluctuations of the proton
- ▶ HERA data does not reach full kinematics accessible at the LHC due to higher energies  
→ measure at the LHC interesting, in particular for lowest  $x$
- ▶ can apply same formalism also to nuclear target

# Hadron-hadron-collision motivation for incoherent production

- ▶ shape fluctuations → understand azimuthal anisotropies

# Initial state shape and hydrodynamic response

- The single-particle distribution is essentially independent of rapidity  $\eta$  but depends on azimuthal angle,  $\varphi$  in each event
- Fourier decomposition :  $f(\varphi) = \sum_n V_n e^{-in\varphi}$
- $v_n = |V_n| = \text{anisotropic flow}$  fluctuates event to event

Initial transverse density profile

Expansion

Final distribution

Elliptic flow  $v_2$

Triangular flow  $v_3$

*In hydrodynamics, anisotropic flow is a response to the anisotropy of the initial density profile.*

taken from from J.-Y. Olltrault's talk at Epiphany conference '19

- ▶ transverse collision-zone **geometry in coordinate space:**  
azimuthal particle **correlations in final state in momentum space**
- ▶ hydrodynamic properties (viscosities) measured as response of this shape
- ▶ constraining shape: central to QGP physics  
→ mechanism exploited to constrain nuclear structure, see [thesis of G. Giuliano](#)

# Proton 'geometry' in proton-nucleus collisions

Initial transverse density profile

Expansion

Final distribution

Elliptic flow  $v_2$

Triangular flow  $v_3$

**YES, also in pPb...  
and probably in pp as well**

- ▶ geometry response observed in proton-nucleus collisions  
Zaijic, Nagle *Ann.Rev.Nucl.Part.Sci.* 68 (2018) 211
- ▶ require sub-nucleonic geometry fluctuations with  $n > 1$  hot-spots  
→ "the proton snapshot with multi-parton interactions is not round"  
e.g. discussed in [PLB 774 \(2017\)](#) [PLB 772 \(2017\)](#)
- ▶ naïve remark: if theory connection solid & modeling controllable, hadron correlations useful to learn about hadron fluctuations, not only nuclear structure

# Saturation physics motivation

Left: Cepila, Contreras, Takaki [PLB766 \(2017\) 186](#), right: Schenke, Mäntisaary [PRD 98 \(2018\) 3, 034013](#)

- ▶ at asymptotically large energies: system becomes black disk  
→ fluctuations vanish and hence dissociative production
- ▶ seen in model calculations, see Renaud's talk later today

# Measurement in pPb collisions

- ▶ 6.5 TeV proton-beam,  $6.5 \cdot Z^{Pb} (= 82)$  TeV lead beam
- ▶ only  $J/\psi$  measurement in spectrometer with momentum information
- ▶  $W_{\gamma^*p} = 2E_p M_{J/\psi} e^{-y}$ ,  $y$  rapidity of  $J/\psi$  w.r.t. proton beam
- ▶  $t \approx -p_{T,jpsi}^2$ , (photon- $k_T \approx 1/R_{Pb}$ )  $\rightarrow t$  hence in principle accessible, however, muon-arm resolution modest  
 $\rightarrow$  measurement not differential in  $t$
- ▶ pPb luminosity:  $7.62 \text{ nb}^{-1}$

# pPb Kinematics in ALICE

- ▶ The  $J/\psi$  goes in the direction of the proton,  $y > 0$ :

$$27 \text{ GeV} < W_{\gamma^* p} < 58 \text{ GeV}$$

$$5 \times 10^{-3} < x < 2 \times 10^{-2}$$

Courtesy by A. Glaenger

# Analysis strategy

- ▶ standard selection and methods for muon analyses in ALICE and UPC
  
- ▶ new features:
  - exclusive selection to fix exclusive contribution shape
  - more open selection including dissociative and exclusive to do fit
  - 2-D loglikelihood fit of mass and  $p_T$  to extract signals
  
- ▶ analysis of  $\gamma\gamma \rightarrow \mu^+\mu^-$  as test of QED part & photon fluxes as bonus (not covered here), ingredient for TCS feasibility

# Key aspect: exclusive selection vetos

- ▶ selection used to derive  $p_T$  distribution of exclusive production
- ▶ also used as cross check

# Exclusive selection

- ▶ tight selection used for exclusive shape determination

# Key aspect: exclusive selection vetos

- ▶ selection used for cross section determination
- ▶ verified via RapGap simulation that V0C vetoes do not introduce inefficiency for dissociative process
- ▶ largest systematic uncertainties for dissociative: V0C veto & exclusive shape

# Analysis key aspect: signal extraction

- ▶ Exclusive: shape fixed with pure exclusive sample
- ▶ Dissociative J/ψ parameterisation following H1
- ▶  $\gamma$ -Pb production fixed from PbPb measurement

# From UPC cross section to photoproduction cross section

$$\frac{d\sigma}{dy}(\text{p} + \text{Pb} \rightarrow \text{p}^{(*)} + \text{Pb} + \text{J}/\psi) = k \frac{dn}{dk} \sigma(\gamma + \text{p} \rightarrow \text{J}/\psi + \text{p}^{(*)}).$$

Rapidity range	$N_{\text{J}/\psi}^{\text{exc}}$ , $N_{\text{J}/\psi}^{\text{diss}}$	$d\sigma_{\text{J}/\psi}^{\text{exc}}/dy$ , $d\sigma_{\text{J}/\psi}^{\text{diss}}/dy$ ( $\mu\text{b}$ )	$kdn/dk$	$W_{\gamma\text{p}}$ (GeV)	$\langle W_{\gamma\text{p}} \rangle$ (GeV)	$\sigma(\gamma + \text{p} \rightarrow \text{J}/\psi + \text{p})$ (nb), $\sigma(\gamma + \text{p} \rightarrow \text{J}/\psi + \text{p}^{(*)})$ (nb)
(2.5, 4)	$1180 \pm 84$	$8.13 \pm 0.58 \pm 0.43$	$209 \pm 4$	(27, 57)	39.9	$39.0 \pm 2.8 \pm 2.2$
	$1515 \pm 83$	$10.43 \pm 0.57 \pm 1.39$				$50.0 \pm 2.7 \pm 6.7$
(3.25, 4)	$564 \pm 53$	$7.16 \pm 0.67 \pm 0.48$	$220 \pm 4$	(27, 39)	32.8	$32.51 \pm 3.0 \pm 2.3$
	$733 \pm 52$	$9.31 \pm 0.66 \pm 1.28$				$42.3 \pm 3.0 \pm 5.9$
(2.5, 3.25)	$629 \pm 54$	$9.21 \pm 0.80 \pm 0.51$	$197 \pm 4$	(39, 57)	47.7	$46.8 \pm 4.1 \pm 2.8$
	$768 \pm 55$	$11.26 \pm 0.80 \pm 1.53$				$57.2 \pm 4.1 \pm 7.8$

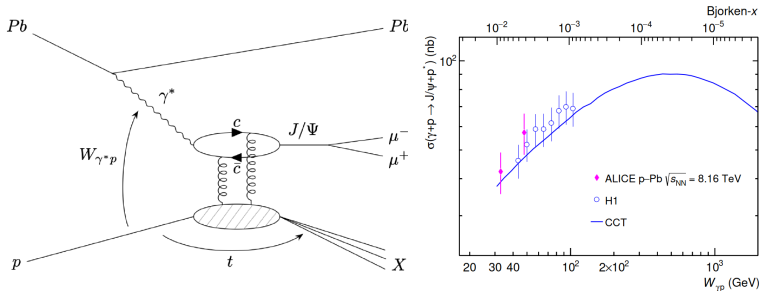

- ▶ to get from measured cross section to photoproduction, need photon-flux from Pb nucleus as input
- ▶ extracted from Starlight event generator
- ▶ exclusive production still statistically limited, dissociative systematically limited

# Exclusive analysis results

- ▶ results of this analysis well in line with previous results

# Dissociative results compared with H1 results and models

► measured dissociative production in  $\gamma - p \rightarrow$  consistent with H1

# Dissociative results compared with H1 results and models

## ▶ next steps:

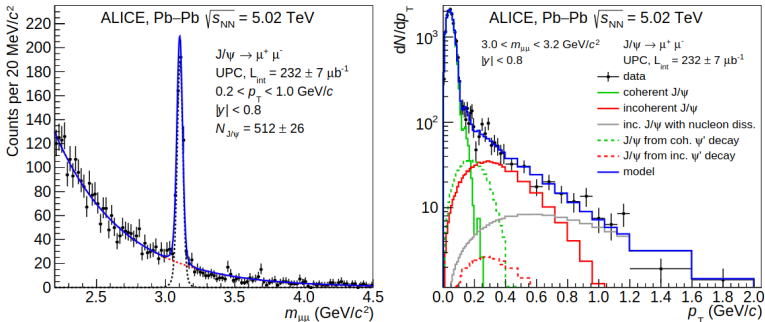

→ future data sets up to  $W_{\gamma p} \approx 1.5$  TeV at the LHC

→ transverse momentum dependence ( $p_t^2 \approx -t$ )

▶ input for hydrodynamic QGP simulations

▶ future studies parallel to electron-ion-collider, but at higher energy

# Incoherent production in PbPb collisions: $t$ -dependence

arXiv:2305.06169, submitted to PRL

- ▶ most recent result:  $t$ -dependence ( $t \approx -p_T^2$ )
- ▶ measurement in ALICE central barrel  $y \approx 0$ : better  $p_T$  resolution, no photon emitter ambiguity
- ▶ separation based on  $p_T$ -templates
- ▶ measurement performed where good S/B for incoherent production:

$$p_T > 0.2 \text{ GeV}/c$$

incoherent production [arXiv:2305.06169](https://arxiv.org/abs/2305.06169)(top), coherent production [PLB 817 \(2021\) 136280](#)(bottom)

- ▶ extraction done in two distinct regions

# $t$ -dependent results in PbPb collisions

left: coherent production, right: incoherent production (MS: Mäntisaary-Schenke) GSZ: Guzey, Strikman, Zhalov)

- ▶  $t$ -dependent coherent production well modeled by leading twist shadowing and b-BK model
- ▶  $t$ -incoherent production not well reproduced by any model, but slope better described when fluctuations subnucleonic scales

# Limitations

- ▶ not yet ultimate LHC luminosity, see HL-LHC Yellow Report [CERN Yellow Rep.Monogr. 7 \(2019\) 1159](#)
  - pPb: need to push for high luminosity
- ▶ Limitation: incomplete reconstruction of final state
  - limits accessible  $t$ -range, measure only where  $S/B$  is sufficiently good for given process & available selections
  - control of veto efficiency limiting systematic uncertainty
  - not capable to reconstruct dissociative system
- ▶ improvement without new instrumentation for better quantification of uncertainties: better MC-generators
  - HERA as benchmark
  - UPCs can profit from EIC theory developments with minor additional effort

# Longer term perspectives

- ▶ Dream for LHC:
  - roman pots for diffractive masses between 3 and 30 GeV
  - at the LHC not available for this mass-range (beam particle inelasticity and  $p_t$  in ATLAS/CMS for BSM)
  - Zero-degree-calorimeters for low- $x$  high-resolution LHCb would be already a great gain
- ▶ Electron-ion-collider:
  - forward instrumentation
  - nuclear case: challenging to go beyond good S/B range as at the LHC

# Conclusions

- ▶ Dissociative quarkonium photoproduction interesting:
  - fluctuations of hadrons with connection to QGP physics
  - saturation physics
- ▶ LHC: higher energy as HERA & EIC, experimentally less clean
- ▶ first measurement at the LHC compatible with HERA results with good precision
- ▶ interesting future measurements at the LHC:
  - higher energy data points
  - t-dependence as in PbPb
- ▶ better event class/observable definition/conception & simulations:
  - reduce uncertainties in future & go further in experiment/theory exchange

## Questions for discussion

- ▶ Can the relation between dissociation and fluctuations be formalised in a way that it can be carried over to hadron-hadron collisions without reference to a model ansatz, i.e. at operator level?  
→ via GPD formalism or other means? What are the limits of applicability/uncertainties of this connection?
- ▶ What do we learn from the dissociative system in this kinematic regime with fully reconstructed final state?
- ▶ In principle, the concepts carry over to nuclear collisions, very interesting for QGP physics & saturation  
→ however: what do we treat nuclear excitation & coherence in inelastic collisions?  
see questions posed by Spencer Klein on caveats/problems [arXiv:2301.01408](https://arxiv.org/abs/2301.01408)
- ▶ What do we know about the quarkonium wave function that can also fluctuate and may not be very 'small' w.r.t. the target, see Demirci, Lappi, Schlichting [PRD 106 \(2022\) 7, 074025](https://arxiv.org/abs/2207.07402)?
