# DISCUSSION

# Questions

- what is the relation between coherent vs. incoherent production and exclusive vs dissociative events ?
for nucleon and nuclear targets ?

- are there cases where exclusive production is incoherent ? e.g. gamma*+A going to gamma+A', where the A' is not in the ground state,

# Questions

- what is the relation between coherent vs. incoherent production and exclusive vs dissociative events ?
            for nucleon and nuclear targets ?

- are there cases where exclusive production is incoherent ? e.g. gamma*+A going to gamma+A', where the A' is not in the ground state,

- are there cases where dissociative production is coherent ? e.g. gamma*+A(208) going to gamma+A(207)+n

- what are the relevant scales for the nuclear excitation yielding to neutron emission to factorise completely from the hard interaction and what are the limits of this approximation ?

- are there cases where dissociative production is coherent ? e.g. gamma*+A(208) going to gamma+A(207)+n

- what are the relevant scales for the nuclear excitation yielding to neutron emission to factorise completely from the hard interaction and what are the limits of this approximation ?

- are there consequences for experimental future instrumentation not yet taken into account?

# Questions

- is there a clean experimental separation between incoherent events with a rapidity gap and non-diffractive events

- how robust is the good-walker picture and what are its limits?

      only valid for t = 0 ?

# Questions

- is there a clean experimental separation between incoherent events with a rapidity gap and non-diffractive events

- how robust is the good-walker picture and what are its limits?
        only valid for t = 0 ?

- robustness of disappearance of fluctuations in the high-energy limit as a consequence of non-linear dynamics in the target.
        is it really a smoking gun of saturation?

# Questions

- how robust is the good-walker picture and what are its limits?
       only valid for t = 0 ?

- robustness of disappearance of fluctuations in the high-energy limit as a consequence of non-linear dynamics in the target.
       is it really a smoking gun of saturation?

- if we can't answer some of those questions now, can we think of tests with specific data comparisons ?
