

MicrOMEGAs 6: new developments and physics applications

Rencontres de Physique des Particules

January 2024

Andreas Goudelis
LPC - Clermont Ferrand

A bit of history: χ_1^0 freeze-out relic density

Already since the early 80's, more and more groups wanted to compute the lightest neutralino relic abundance in the Minimal Supersymmetric Standard Model:

- 28 new particles (+ 17 from the SM).
- All of them can, in principle, coannihilate (either with χ_1^0 or among them).
- In full generality, this amounts to:
 - Calculating matrix elements for ~ 3000 processes.
 - Writing down numerical code to evaluate them.
 - Writing down the relevant Boltzmann equations.
 - Writing down numerical code to solve them.

People *did* do all that and, by the early 2000's, started developing public codes.

→ Common feature: all relevant expressions were *hard-coded*.

This procedure had to be repeated for every new model

Development of micrOMEGAs

MicrOMEGAs is a numerical code for the calculation of dark matter properties

<p>micrOMEGAs: A program for calculating the relic density in the MSSM</p> <p>G. Bélanger¹, F. Boudjema¹, A. Pukhov², A. Semenov¹</p>	<p>Neutralino DM relic density in the MSSM. Based on CompHEP for ME calculation.</p> <p>arXiv:hep-ph/0112278</p>
<p>micrOMEGAs 2.0: a program to calculate the relic density of dark matter in a generic model .</p> <p>G. Bélanger¹, F. Boudjema¹, A. Pukhov², A. Semenov³</p>	<p>Freeze-out calculation of DM relic density in generic extensions of the SM. CalcHEP.</p> <p>arXiv:hep-ph/0607059</p>
<p>micrOMEGAs_3 : a program for calculating dark matter observables</p> <p>G. Bélanger¹, F. Boudjema¹, A. Pukhov², A. Semenov³</p>	<p>Asymmetric DM, semi-annihilations, generalized thermodynamics, DD/ID/LHC.</p> <p>arXiv:1305.0237</p>
<p>micrOMEGAs4.1: two dark matter candidates</p> <p>G. Bélanger¹, F. Boudjema¹, A. Pukhov², A. Semenov³</p>	<p>Two generic frozen-out dark matter components.</p> <p>arXiv:1407.6129</p>
<p>micrOMEGAs5.0 : freeze-in</p> <p>G. Bélanger^{1†}, F. Boudjema^{1†}, A. Goudelis^{2§}, A. Pukhov^{3¶}, B. Zaldivar^{1††}</p>	<p>Incorporation of freeze-in dark matter production mechanism (one-component).</p> <p>arXiv:1801.03509</p>
<p>micrOMEGAs 6.0: N-component dark matter</p> <p>G. Alguero¹, G. Bélanger², F. Boudjema², S. Chakraborti³, A. Goudelis⁴, S. Kraml¹, A. Mjallal², A. Pukhov⁵</p>	<p>Arbitrary number of (frozen in/out) dark matter components.</p> <p>arXiv:2312.14894</p>

+ intermediate versions. Until 2013, the *only* DM code to handle generic SM extensions.

So, what is micrOMEGAs ?

<https://lapth.cnrs.fr/micromegas/>

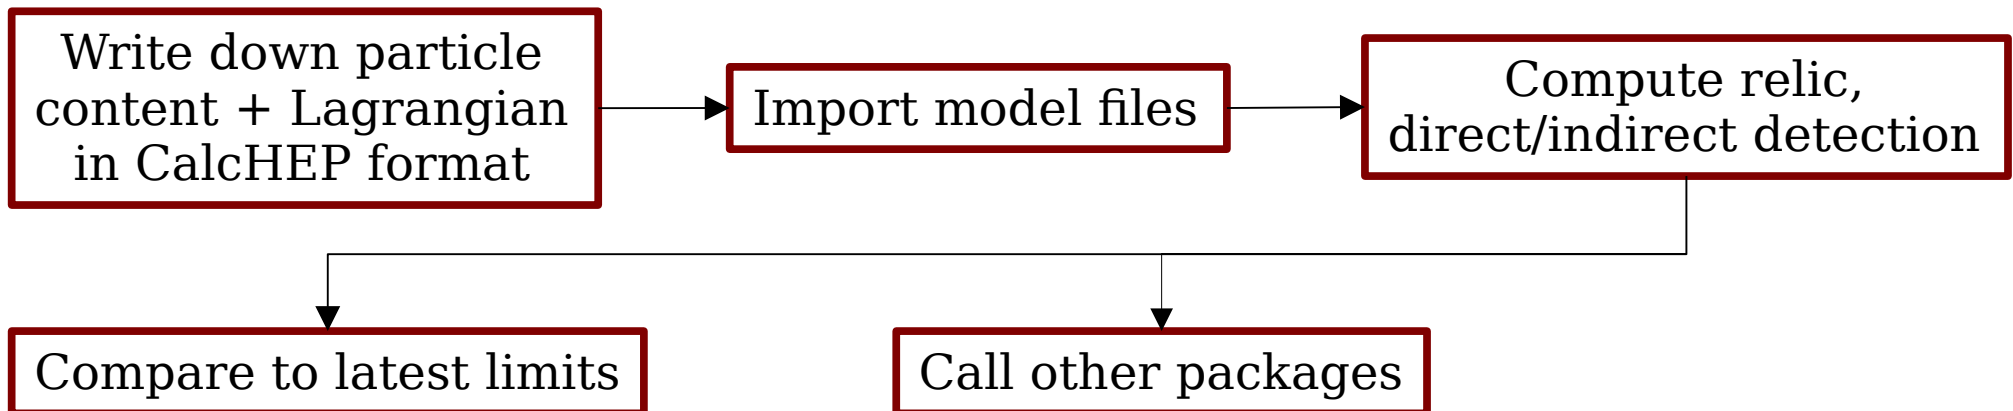

A C/Fortran code to compute dark matter observables for generic dark matter candidates (current version: v6). For any BSM model, the code can:

- Figure out which processes are relevant for the evolution of the freeze-out/freeze-in dark matter cosmic abundance.
- Compute the relevant matrix elements.
 - Based on CalcHEP. By default tree-level $1/2 \leftrightarrow 2$, possibility for some $2 \rightarrow 3/4$. Possibility to replace $\langle\sigma v\rangle$ with own expression.
- Solve the necessary Boltzmann equations.
- Compute additional observables, compare to EXP limits, link to other packages.

So, what is micrOMEGAs ?

A C/Fortran code to compute dark matter observables for generic dark matter candidates (current version: v6). For any BSM model, the code can:

- Figure out which processes are relevant for the evolution of the freeze-out/freeze-in dark matter cosmic abundance.
- Compute the relevant matrix elements.

- Solve the necessary Boltzmann equations.
- Compute additional observables, compare to EXP limits, link to other packages.

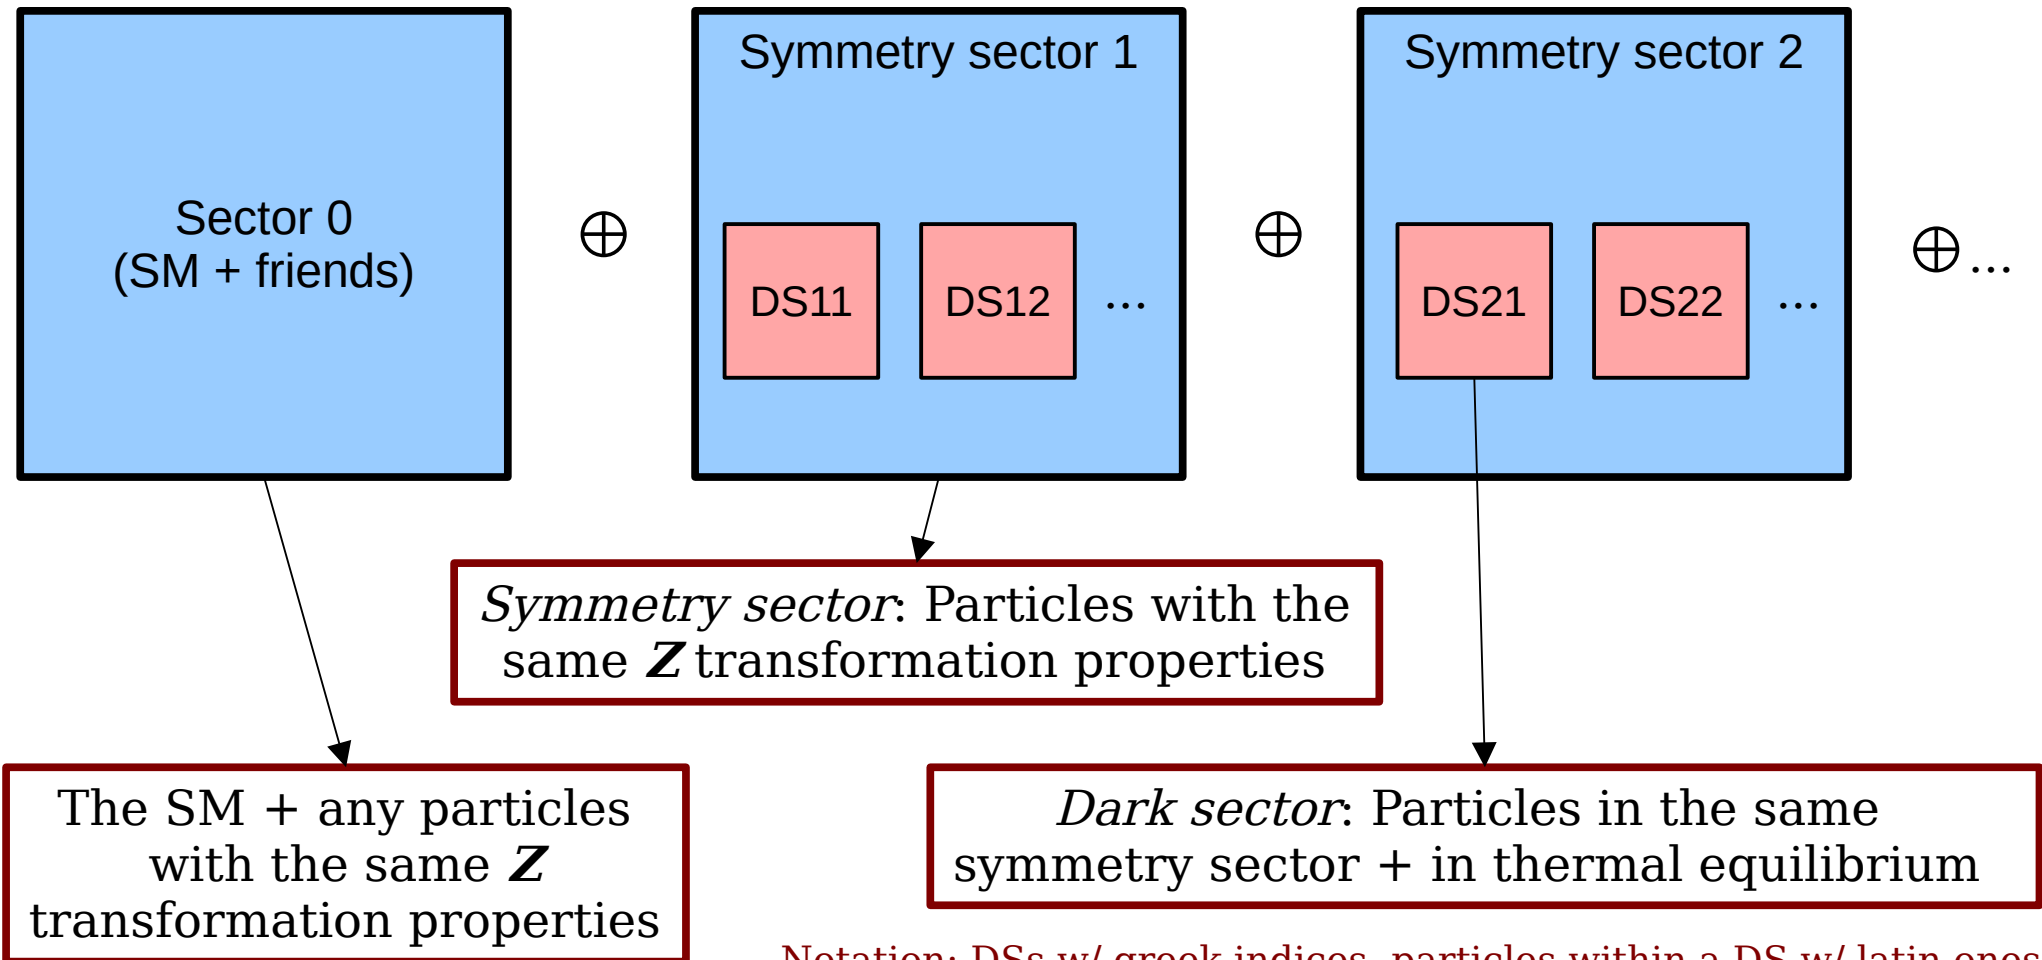

What is new in MO6 ?

Numerous new features have been implemented in the latest version :

- Major upgrade : possibility to compute the DM cosmic abundance in models with multiple WIMP+FIMP dark matter candidates + consistent computation of relevant experimental constraints.
- Major upgrade : inclusion of conversion-driven freeze-out (“co-scattering”) and decay terms.
- Possibility to define (and, partly, check) which sets of particles are in thermal equilibrium.
- Possibility to include $2 \rightarrow 3$ and $2 \rightarrow 4$ processes in single-component DM models.
- Improvements in freeze-in computations.
- Additional functionalities for direct/indirect detection.

Multi-component dark matter : strategy

Types of models handled in MO : one (or more) discrete symmetries Z_i are imposed at the Lagrangian. Different (sets of) particles may transform differently under the direct product $Z = Z_1 \otimes Z_2 \otimes \dots \otimes Z_N$ of these symmetries. We divide the model content in *sectors*.

Notation: DSs w/ greek indices, particles within a DS w/ latin ones

Multi-WIMP case

Any DS may (or may not) contain a dark matter candidate. The evolution of the μ -th candidate's abundance as a function of the entropy density follows :

$$3H \frac{dY_\mu}{ds} = \sum_{\alpha \leq \beta; \gamma \leq \delta} Y_\alpha Y_\beta C_{\alpha\beta} \langle v \sigma_{\alpha\beta\gamma\delta} \rangle (\delta_{\mu\alpha} + \delta_{\mu\beta} - \delta_{\mu\gamma} - \delta_{\mu\delta})$$

where:

$$\langle v \sigma_{\alpha\beta\gamma\delta} \rangle = \frac{1}{C_{\alpha\beta} \bar{n}_\alpha(T) \bar{n}_\beta(T)} \sum_{\substack{a \in \alpha, b \in \beta, c \in \gamma, d \in \delta \\ \text{if } (\alpha=\beta) a \leq b; \text{ if } (\gamma=\delta) c \leq d}} \bar{N}_{a,b \rightarrow c,d}$$

$$\bar{N}_{a,b \rightarrow c,d} = \frac{T g_a g_b}{8\pi^4} \int \sqrt{s} p_{ab}^2(s) K_1\left(\frac{\sqrt{s}}{T}\right) C_{ab} \sigma_{a,b \rightarrow c,d}(s) ds$$

Multi-WIMP case

Any DS may (or may not) contain a dark matter candidate. The evolution of the μ -th candidate's abundance as a function of the entropy density follows :

$$3H \frac{dY_\mu}{ds} = \sum_{\alpha \leq \beta; \gamma \leq \delta} Y_\alpha Y_\beta C_{\alpha\beta} \langle v\sigma_{\alpha\beta\gamma\delta} \rangle (\delta_{\mu\alpha} + \delta_{\mu\beta} - \delta_{\mu\gamma} - \delta_{\mu\delta})$$

where:

$$\langle v\sigma_{\alpha\beta\gamma\delta} \rangle = \frac{1}{C_{\alpha\beta} \bar{n}_\alpha(T) \bar{n}_\beta(T)} \sum_{\substack{a \in \alpha, b \in \beta, c \in \gamma, d \in \delta \\ \text{if } (\alpha=\beta) a \leq b; \text{ if } (\gamma=\delta) c \leq d}} \bar{N}_{a,b \rightarrow c,d}$$

$$\bar{N}_{a,b \rightarrow c,d} = \frac{T g_a g_b}{8\pi^4} \int \sqrt{s} p_{ab}^2(s) K_1\left(\frac{\sqrt{s}}{T}\right) C_{ab} \sigma_{a,b \rightarrow c,d}(s) ds$$

If some particle species in a DS decay slowly, we get additional terms of the type :

$$\frac{1}{s^2(T)} \sum_{\alpha; \gamma \leq \delta} \left(\frac{Y_\alpha}{\bar{Y}_\alpha} - \frac{Y_\beta Y_\gamma}{\bar{Y}_\beta \bar{Y}_\gamma} \right) (\delta_{\mu\alpha} - \delta_{\mu\beta} - \delta_{\mu\gamma}) \sum_{a \in \alpha, c \in \beta, d \in \gamma} \bar{N}_{a \rightarrow c,d}$$

where:

$$\bar{N}_{a \rightarrow c,d} = \frac{T g_a}{2\pi^2} m_a^2 \Gamma^0(a \rightarrow c, d) K_1\left(\frac{m_a}{T}\right)$$

Including co-scattering, freeze-in

Co-scattering corresponds to processes of the type $\mu + 0 \rightarrow \nu + 0$. It turns out that these contributions enter the Boltzman eqs. similarly to decay terms $\mu \rightarrow \nu + 0$

$$3H \frac{dY_\mu}{ds} \approx (Y_\mu - Y_\nu \frac{\bar{Y}_\mu}{\bar{Y}_\nu}) \Gamma_{\mu \rightarrow \nu}$$

where:

$$\Gamma_{\mu \rightarrow \nu} = \frac{Y_0 \langle \sigma_{\mu 0 \nu 0} \rangle (T) + \sum_{a \in \mu, c \in \nu} g_a m_a^2 \Gamma^0(a \rightarrow c, 0) K_1\left(\frac{m_a}{T}\right) + \sum_{a \in \nu, c \in \mu} g_a m_a^2 \Gamma^0(a \rightarrow c, 0) K_1\left(\frac{m_a}{T}\right)}{\sum_{a \in \mu} g_a m_a^2 K_2\left(\frac{m_a}{T}\right)}$$

can be seen as an effective width between sectors μ and ν .

Freeze-in can also be implemented through the same set of equations, but setting the initial DM abundance to zero as usual.

• Important difference wrt single-component case: DM annihilations *are* taken into account.

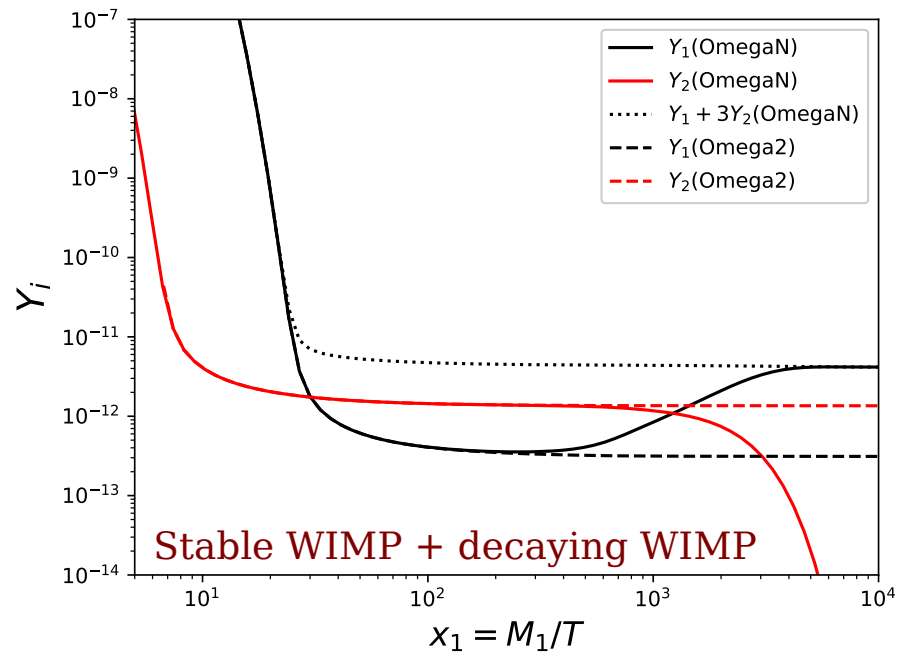

NB: Kinetic equilibrium is assumed even for FIMPs, otherwise need to solve un-integrated Boltzmann eqs!

Validation and example results

The code was validated using different models as examples :

- Singlet scalar (sanity checks for single-component DM, 1 WIMP or 1 FIMP).
- Z5M (two singlets w/ Z_5 symmetry, 2 WIMPs or 1 WIMP + 1 FIMP).
- Z4IDSM (Inert Doublet plus Singlet w/ Z_4 symmetry, 1 WIMP + 1 FIMP).

Two examples from the Z5M :

Decay occurs through $\lambda \varphi_2 \varphi_1^3$ coupling

Decay occurs through $\mu \varphi_2 \varphi_1^2$ coupling

Excellent agreement w/ previous versions until decays become relevant.

Issues with t -channels : the problems

Although in principle quite straightforward, processes involving particle exchange in the t -channel may present some peculiarities :

Spin-1 particle exchange leads to constant σ at high temperatures $\rightarrow Y_{\text{DM}} \sim T_{\text{R}}$ even for renormalizable models.

Issue only appears in FI

If a stable particle is exchanged in the t -channel, σ diverges as the particle becomes on-shell.

Issue appears both in FI and in FO

Both problems appear due to the utilisation of zero-temperature, in-vacuum QFT. Physically, they are *fictitious*.

Issues with t -channels : the problems

Spin-1 particle exchange leads to constant σ at high temperatures $\rightarrow Y_{\text{DM}} \sim T_{\text{R}}$ even for renormalizable models.

Issue only appears in FI

If a stable particle is exchanged in the t -channel, σ diverges as the particle becomes on-shell.

Issue appears both in FI and in FO

Both problems appear due to the utilisation of zero-temperature, in-vacuum QFT. Physically, they are *fictitious*.

In particular, *in a medium*, at finite temperature :

- The vector mass receives a T -dependent contribution that scales as $M^2 \sim T^2$.
- Every particle (even a stable one) has a finite absorption probability (“width”).

Issues with t -channels : solutions

Computing full-blown thermal corrections to masses/widths is beyond the scope of micrOMEGAs.

Matrix elements calculated at *tree-level*

NB: We *cannot* simply replace T-dependent masses (gauge invariance).

Issues with t -channels : solutions

Computing full-blown thermal corrections to masses/widths is beyond the scope of micrOMEGAs.

Matrix elements calculated at *tree-level*

NB: We *cannot* simply replace T -dependent masses (gauge invariance).

Observation : consider $e^+ e^- \rightarrow \nu_e \bar{\nu}_e$ and compute the integrated cross-section with a cut c on the scattering angle

$$\begin{aligned} \sigma(\sqrt{s}, M_W, c) = & 4\hat{\sigma}_{e\nu_e} \left(\frac{1}{2\mu^2 + c} + \log \left(\frac{2\mu^2 + c}{2} \right) + \mu^2 \log \left(\frac{2\mu^2 + c}{2} \right) + 1 - c \right. \\ & \left. + \frac{c^2}{4(-2 + c - 2\mu^2)} + \frac{c(c - 4)}{4(c + 2\mu^2)} - (1 + \mu^2) \log \left(1 + \mu^2 - c/2 \right) \right) \end{aligned}$$

Where $\mu^2 = M_W^2/s$, $\hat{\sigma}_{e\nu_e} = \pi\alpha^2/(8s_W^4 s)$ and $\{\mu, c\}$ enter both singularities through the same combination $2\mu^2 + c$

The effect of a T -dependent mass can be captured by a zero-temperature calculation with a T -dependent cut on the scattering angle (or the p_T).

In practice: user-defined p_T cuts for all relevant particles

Issues with t -channels : solutions

Computing full-blown thermal corrections to masses/widths is beyond the scope of micrOMEGAs.

Matrix elements calculated at *tree-level*

NB: We *cannot* simply replace T -dependent masses (gauge invariance).

Observation : consider $e^+ e^- \rightarrow \nu_e \bar{\nu}_e$ and compute the integrated cross-section with a cut c on the scattering angle

$$\begin{aligned} \sigma(\sqrt{s}, M_W, c) = & 4\hat{\sigma}_{e\nu_e} \left(\frac{1}{2\mu^2 + c} + \log \left(\frac{2\mu^2 + c}{2} \right) + \mu^2 \log \left(\frac{2\mu^2 + c}{2} \right) + 1 - c \right. \\ & \left. + \frac{c^2}{4(-2 + c - 2\mu^2)} + \frac{c(c - 4)}{4(c + 2\mu^2)} - (1 + \mu^2) \log \left(1 + \mu^2 - c/2 \right) \right) \end{aligned}$$

Where $\mu^2 = M_W^2/s$, $\hat{\sigma}_{e\nu_e} = \pi\alpha^2/(8s_W^4 s)$ and $\{\mu, c\}$ enter both singularities through the same combination $2\mu^2 + c$

The effect of a T -dependent mass can be captured by a zero-temperature calculation with a T -dependent cut on the scattering angle (or the p_T).

In practice: user-defined p_T cuts for all relevant particles

For stable particles: introduce a small width $\sim M/100$ for t -channel particles.

Improvements for other observables

- **Direct detection:**

In general multi-component models, one cannot naïvely impose DD limits: simple rescaling by the fraction of each component is not enough.

In MO6 a function is provided in order to compute whether a model is excluded or not by the leading DD experiments.

- **Indirect detection:**

In previous versions the DM annihilation - induced photon spectra (Pythia 6) were tabulated down to DM masses of ~ 2 GeV. For lighter DM, need to consider different final states.

In MO6 the gamma-ray tables have been updated/improved to include annihilations into light leptons, pions, Kaons.

- **Structure formation:**

Free-streaming length of DM particles through:

$$\lambda_{FS} = \int_{T_2}^{T_1} \left(1 + \left(\frac{a(T)m}{a(T_1)p} \right)^2 \right)^{-\frac{1}{2}} \frac{dT}{a(T)\bar{H}(T)T}$$

Summary and outlook

- MicrOMEGAs can now handle scenarios with multiple dark matter components.
- MicrOMEGAs can now handle conversion-driven freeze-out (“co-scattering”) and decaying long-lived particles.
- Numerous improvements have been introduced both for the calculation of the relic density (taming singular behaviours, multi-body final states) and of different observables (DD/ID, free-streaming length).
- Next version? We’ll see... :)
