# Direct dark matter detection

## Dark matter

- ❖ No charge
- ❖ No self-interaction
- ❖ Cold
- ❖ Stable

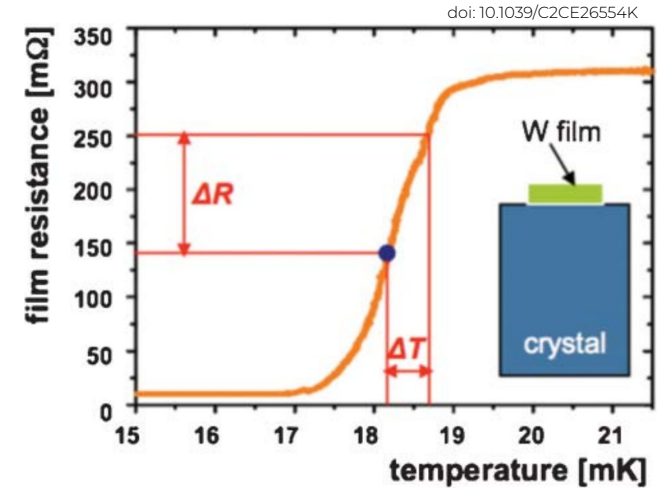

## WIMP

- ❖ All above and...
- ❖  $O(\text{GeV})$  mass

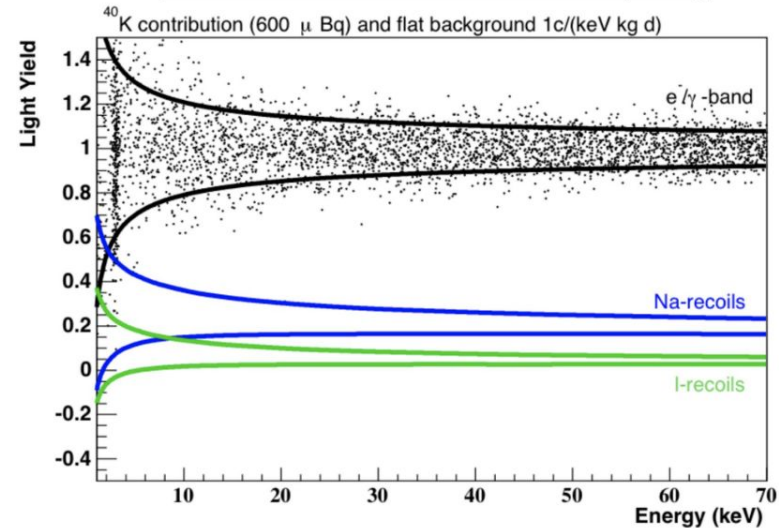

# Cryogenic detectors

# Cryogenic detectors

## Particle discrimination (NaI)

$$\text{Light yield} = \frac{\text{Energy in Light}}{\text{Total Energy}}$$

# COSINUS

Cryogenic **O**bservatory for **S**ignals seen in **N**ext Generation **U**nderground **S**earches

HELSINKI 2023

# DM signal annual modulation

→ Movement of Earth respect to DM wind should lead to an annual modulation of the DM signal.

→ DAMA/LIBRA (here below) claims to have seen DM annual modulation with a **13.7 $\sigma$**  significance.

# The DAMA/LIBRA claim

→ This result has been excluded by several other experiments...

# The DAMA/LIBRA claim

→ This result has been excluded by several other experiments...

→ But no NaI-based experiment in a model independent way yet!

# The COSINUS experiment

→ Same cryogenic technology used by CRESST, utilizing NaI crystals, to carry out a **model-independent verification** of the DAMA/LIBRA signal.

→ Same site as DAMA/LIBRA (LNGS)

→ Practically background freedom (active and passive shielding), particle discrimination and better energy resolution allow COSINUS to look not for annual modulation, but **total event rate**, eliminating the possibility of other annually-modulated background sources.

# The remoTES design

→ Quite a special challenge: NaI is hygroscopic, soft and has a low ( $\sim 650$  °C) melting point.

# The remoTES design

→ Quite a special challenge: NaI is hygroscopic, soft and has a low ( $\sim 650^\circ\text{C}$ ) melting point.

- Physical decoupling of TES from crystal
- Easy to reproduce
- It worked on Silicon and  $\text{TeO}_2$

# Above ground proof of principle

- ◆ NaI (3.7g; 10x10x10mm<sup>2</sup>), W-TES on Al<sub>2</sub>O<sub>3</sub> wafer.
- ◆ Baseline resolution: 2 keV
- ◆ Energy threshold: 15 keV
- ◆ Test with neutron (AmBe) source showed **particle discrimination** (population below e/γ band)

# First underground measurement

- ◆ NaI (3.67g; 10x10x10mm<sup>2</sup>), W-TES on Al<sub>2</sub>O<sub>3</sub> wafer.
- ◆ Baseline resolution: 0.44(1) keV
- ◆ Energy threshold: 2.66(4) keV
- ◆ Light channel (Si with remoTES design) yields ~1keV<sub>ee</sub> energy resolution.

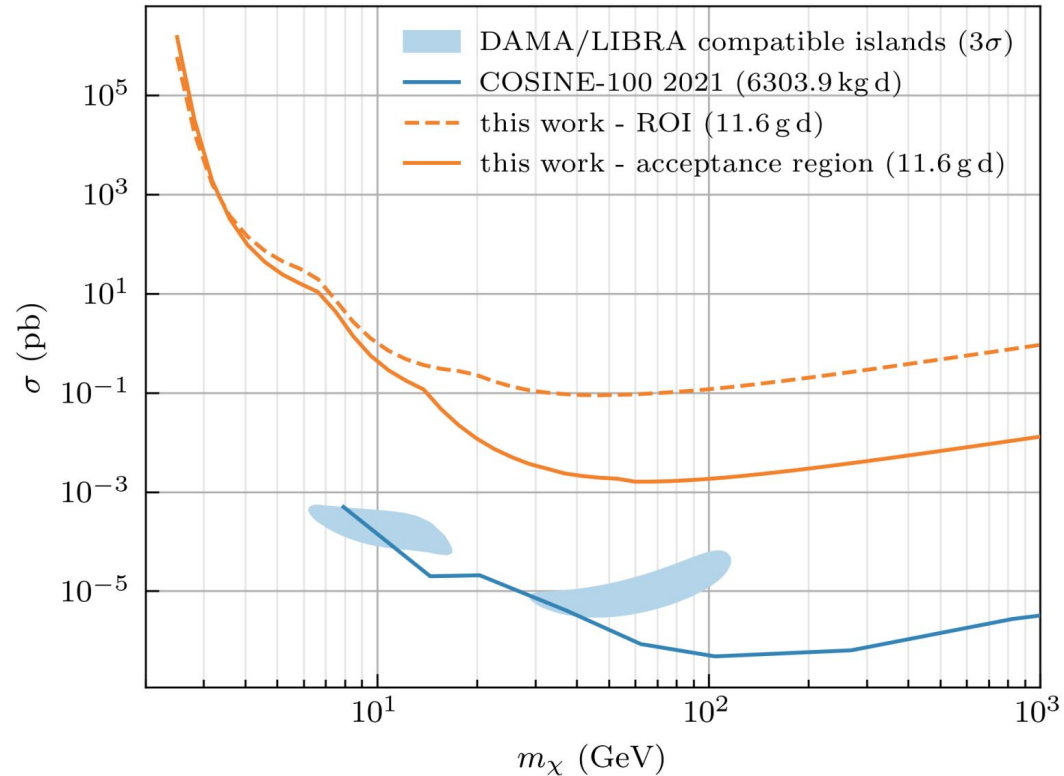

# First underground measurement

- ◆ Unbinned likelihood-fit tool that models all signals present in data.
- ◆ Neutron AmBe source + particle discrimination allows to estimate quenching factor for Na ( $\sim 0.2@10\text{keV}$ ) and I ( $\sim 0.08@10\text{keV}$ ) on the fly.
- ◆ 11.6 gram-day exposure data for DM search (only background - no source)

# First underground measurement

- ◆ DM exclusion limits (90% CL) using Yellin's optimum interval method.
- ◆ Dashed vs continuous line shows limit enhancement due to event-by-event particle discrimination
- ◆ A 11.6 gram-days prototype@LNGS stands  $\sim 2$  orders above COSINE-100's 6303.9 **kg**-days run

# The COSINUS experiment site

# The COSINUS experiment site

# The COSINUS experiment site

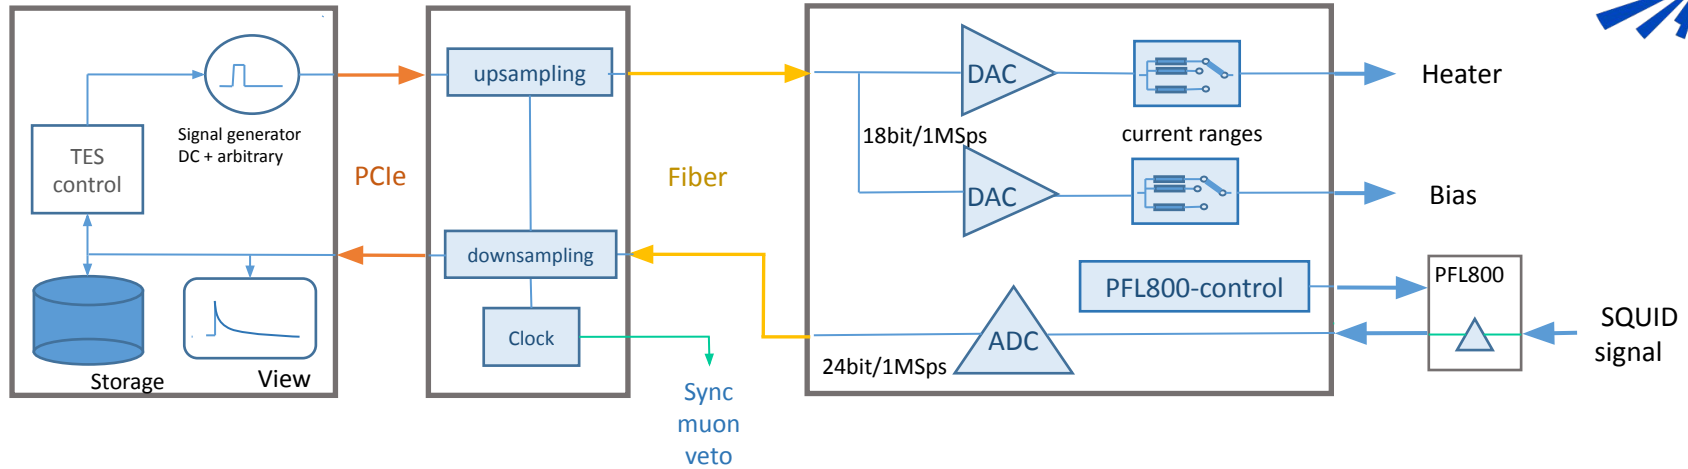

- ◆ Clear division in multiple working areas
- ◆ Instrumented water tank for muon veto, surrounding cryostat.
- ◆ Cleanroom facility above cryostat/water tank for easy access and sample manipulation

# Data acquisition system

vdaq3

- ◆ One integrated system for current sources and digitizers, also integrated to VCCS
- ◆ Optical link (2 fiber cables only) to the server
- ◆ Continuous data taking only (24bits, 1MHz)
- ◆ SQUID amplifiers controlled in the same system

# The COSINUS experiment site: status report

✓ Construction site concluded around mid-2023

# The COSINUS experiment site: status report

- ✓ Construction site concluded around mid-2023
- ✓ Functional and equipped (i.e., espresso machine) offices

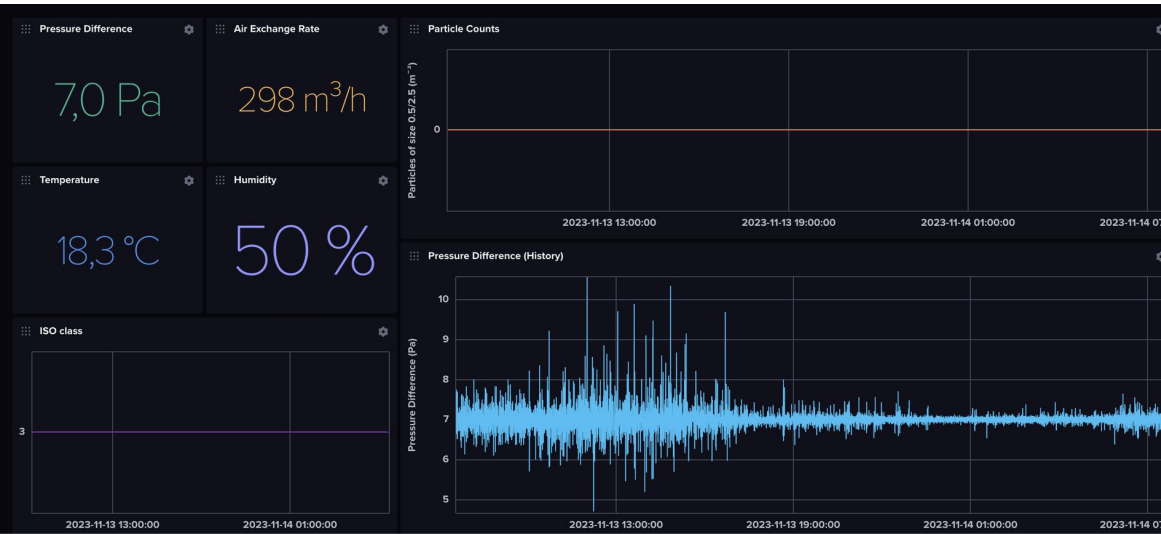

# The COSINUS experiment site: status report

- ✓ Construction site concluded around mid-2023
- ✓ Functional and equipped (i.e., espresso machine) offices
- ✓ Cleanroom facility (Class 10000) functional since August, with remote screening of environmental and operational variables
