 $L_{\text{max}}=kB$   $R_{\text{max}}$ 

How long ∆ of mass *m* lives?

Wavepacket sent into a volume of radius *R*. How long does it stay there?

$$
\tau_{\text{vol}} = \frac{1}{N} \int \mathrm{d}t \, t \oint \mathrm{d}\vec{\sigma} \cdot \vec{j}(\vec{r}, t)
$$

?Change compared to free passage:

$$
\Delta \tau = \tau_{\text{vol}} - \tau_{\text{vol}}^{\text{free}} = \frac{1}{N} \int dt \, t \oint d\vec{\sigma} \cdot [\vec{j} - \vec{j}^{\text{tree}}]
$$

$$
= \frac{d\delta_J}{dE} = \dots = - \int dt \, t \, \frac{d}{dt} \int_V [|\Psi|^2 - |\Psi^{\text{free}}|^2]
$$

for scattering in one partial wave Close femtoscopy connection

[Concluding](#page-12-0) **Comments** 

Spin-averaged kernel *K* in the 3D Koonin-Pratt relation depends only on the relative angle between **q** and **r** - can be expanded in Legendre polynomials:

$$
K(\mathbf{q}, \mathbf{r}) = \sum (2\ell + 1) K_{\ell}(q, r) P^{\ell}(\cos \theta)
$$

Ability to learn on source deformation depends on nonvanishing  $K^{\ell}$  for  $\ell > 0$ . E.g., repulsive Coulomb trajectories appropriate for IMF-IMF correlations, firmly map source deformation onto correlation deformation

#### Expansion Options for Source and Correlation Spherical vs Cartesian

Research [w/Scott Pratt](#page-0-0) P. Danielewicz

[Scott Pratt](#page-1-0) [Career](#page-1-0) [Joint Projects](#page-2-0)

Delays in **Elementary** [Interactions](#page-3-0) [Resolution?](#page-4-0)

[Source Imaging](#page-6-0) [Imaging Pcple](#page-6-0) [3D Imaging](#page-7-0)

[Balance Functions](#page-11-0)

[Concluding](#page-12-0) **Comments** 

$$
K(\mathbf{q}, \mathbf{r}) = \sum_{\ell} (2\ell + 1) K_{\ell}(q, r) P^{\ell}(\cos \theta_{\mathbf{q} \mathbf{r}})
$$
  
Expansion options for asymmetry handling:  
spherical **tesseral** (Brown *et al*) or **cartesian** (PD\&P*rat*) harmonics  

$$
P^{\ell}(\cos \theta_{\mathbf{q} \mathbf{r}}) = \frac{4\pi}{2\ell + 1} \sum_{m} Y_{\ell m}^{*}(\hat{\mathbf{q}}) Y_{\ell m}(\hat{\mathbf{r}}) = (2\ell - 1)!! \sum_{\ell} \frac{1}{\ell_{x}! \ell_{y}! \ell_{z}!} \mathcal{A}_{\ell}(\hat{\mathbf{q}}) \mathcal{A}_{\ell}(\hat{\mathbf{r}})
$$
  
These yield  

$$
S(\mathbf{r}) = \sqrt{4\pi} \sum_{\ell m} S_{\ell m}^{*}(r) Y_{\ell m}(\hat{\mathbf{r}}) = \sum_{\ell} \frac{1}{\ell_{x}! \ell_{y}! \ell_{z}!} S_{\ell}(r) \mathcal{A}_{\ell}(\hat{\mathbf{r}})
$$

and similar expansions for  $R(\mathbf{q}) = C(\mathbf{q}) - 1$ . Irrespectively which expansion is used, *K*<sup>ℓ</sup> connects the corresponding deformation coefficients for *R* (or *C*) and *S*,

$$
\mathcal{R}_{\ell m,\ell}(q) = 4\pi \int \mathrm{d}r \, r^2 \, K_{\ell}(q,r) \, S_{\ell m,\ell}(r)
$$

Which Expansion? Spherical or Cartesian Tensors

**MICHIGAN STATE** 

[Concluding](#page-12-0) **Comments** 

Spherical tensors, Yℓ*m*(*n*ˆ), and expansion coefficients in their basis are complex functions. The basis distinguishes a specific axis and transformation properties under rotations are involved.

Traceless Maxwell-Cartesian tensors,  $A$ <sub>ℓ</sub>( $\hat{n}$ ), and expansion coefficients in their basis are real functions. The axes are treated democratically and transformation properties under rotations are straightforward.

E.g., correlation function *C* cartesian-expanded correlation up to rank  $\ell = 2$ :

$$
C(\mathbf{q}) = C^{(0)}(q) + \sum_{i} C_{i}^{(1)}(q) \hat{q}_{i} + \sum_{j} C_{ij}^{(2)}(q) \hat{q}_{i} \hat{q}_{j} + \dots
$$
  
Here,  $C_{i}^{(1)}(q)$  is a vector function describing a dipole distortion and  $C_{ij}^{(2)}$  is a traceless matrix, that can be diagonalized, describing a quadrupole distortion.

# Identical  $\pi$  Correlations in Pb+Pb at  $\sqrt{s} = 17.3$  GeV/u NA49 . . . Pratt PLB 685(10)41

MICHIGAN STATE

[Concluding](#page-12-0) **Comments** 

- *z* beam direction
- $x$   $P^{\perp}$  of the pair direction
- *y* perpendicular to *x* & *z*

The data described well by the hump function, inspired by the 3D imaging,

$$
S(r) = \Lambda \exp \left[ -\frac{f_s(r) r^2}{r_s^2} - (1 - f_s(r)) \left( \frac{x^2}{x_f^2} + \frac{y^2}{y_f^2} + \frac{z^2}{z_f^2} \right) \right]
$$

where  $f_s(r) = 1/[1 + (r/r_0)^2]$ . The hump function evolves from a spherical Gaussian at short distances to an anisotropic one at long.
