Magicity vs Superfluidity: Neutron correlations in the heavy F isotopes (online)

Tuesday, November 5, 2024 3:45 PM (25 minutes)

Nuclear structure evolves dramatically in asymmetric systems, particularly near the drip lines. A notable example is the “Island of Inversion”, where the magic neutron number $N=20$ breaks down, as established for proton number $Z=10-13$. We study the structure of the most neutron-rich Fluorine ($Z=9$) isotopes around $N=20$ using the SAMURAI spectrometer at RIBF/RIKEN. Measurements were performed in inverse and complete kinematics with radioactive-ion beams at ~ 250 MeV/u incident on a LH2 target. The first measurement of the neutron-unbound 30F isotope via the invariant mass method confirms the breakdown of the $N=20$ magic number, thus extending the “Island of Inversion”, with significant consequences for the F and O isotopes. Large-scale shell model calculations suggest that ^{29}F and ^{28}O are superfluid nuclei where neutron pairs scatter between shells, potentially transitioning into a BEC-like regime with small size pairs. Future experiments are being developed to further investigate these correlations.
