

Global reconstruction: Matching of tracks between SFGD and bHAT

Anaëlle Chalumeau

LPNHE neutrino group meeting – 15/05/2024

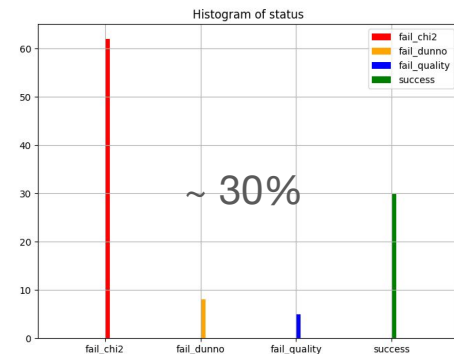

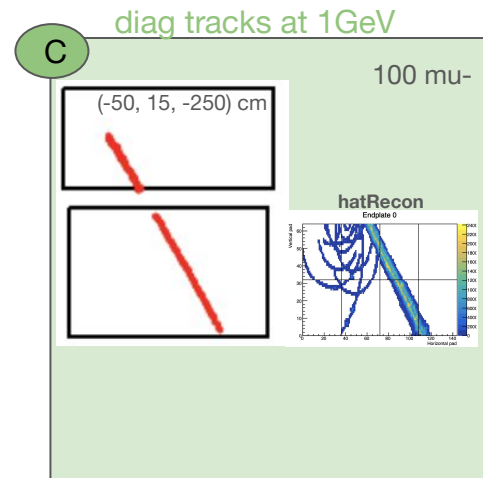

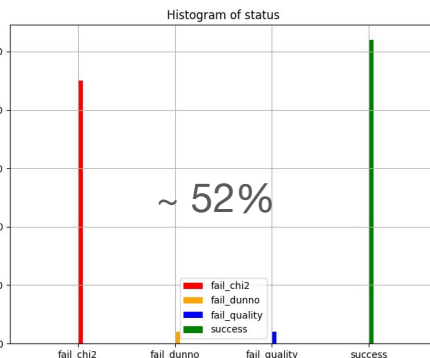

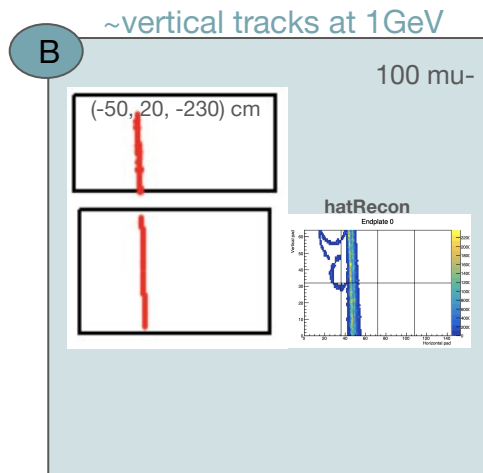

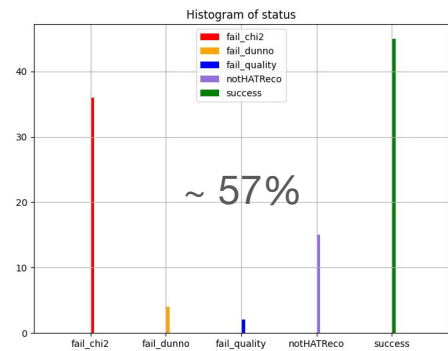

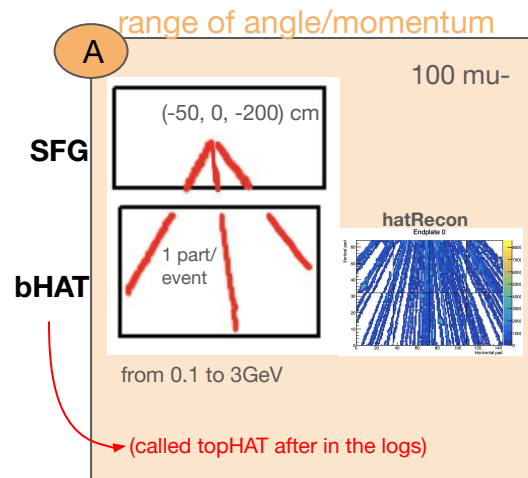

Introduction

- Global reconstruction = matching tracks reconstructed in each detector into one global track in ND280
- Matching of tracks done with the **eventRecon** package: performs global reconstruction in ND280
→ first updated to include SFGD-bHAT matching (work of W.Saenz following what was done for SFGD-TPC1)
- Package dependences:

- Between SFGD and TPC1, expected matching efficiency > 90% (if no cuts) cf [T2K-TN-483](#)
- Goals:
 - find back similar matching efficiency b/n SFGD and TPC1 ✓
 - study matching efficiency b/n SFGD and bHAT ✓ : efficiency < 60% 😞
 - improve the latter: **add HAT where it's missing** and **adapt things to its specificities**

Previous status of the matching efficiency = #matched tracks / #tracks recon by both detectors

What was modified since

use also HAT for PID

- define a function **MergeHatSfgObjects()** similar to **MergeTpcSfgObjects()** but which do not use momentum, x and tx for matching since this gives best matching efficiency (see next slides)

- corrected the track χ^2 values (that is given as track quality)
- add track status of **ND::TReconBase::kLikelihoodFit**
- corrected how p and q parameters are set for the node states
- corrected some bug in the reconstruction of the x position

- in **TRecPackMatchingSurfaceMarker**: add HAT surface definitions similarly to TPC treatment
- in **TRecPackMatchingSurfaceMarker**: change SFG to something similar to FGD but propagates to surface in Y for HAT tracks (instead of Z with TPC tracks)
- add missing HAT in **TMergingUtils**

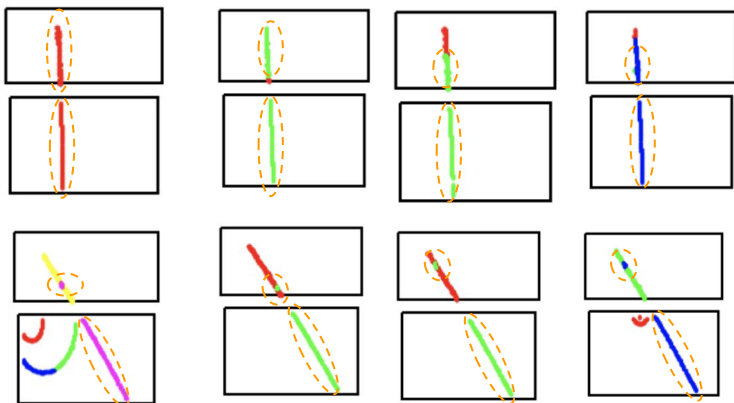

add HAT and corrected top/bottom numerotation to 1/0

Condition for tracks to be considered as matched

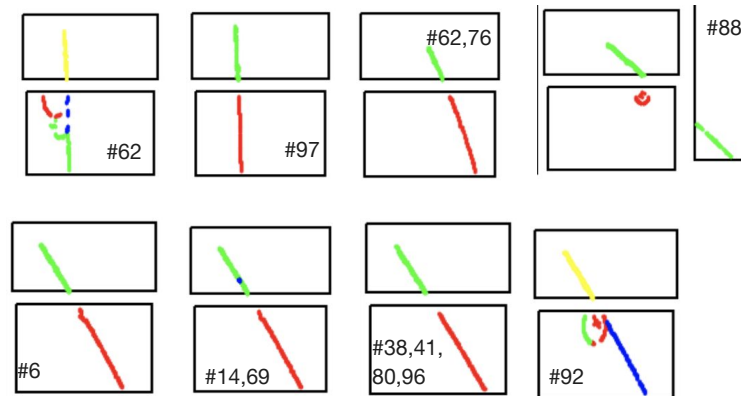

There is **at least one successful match and merge** between a SFGD and a HAT track, i.e. **at least one merged object**:

```
---> Fit OK: (SFG-BottomHAT) PID (0x1d0385f0): #hits = 240, #cons = 2, #nodes = 41,  
status = (success:kalman), ndof = 81, chi2 = 77.0217, p = 38.3755, q = -1, t = 8440,  
PID = Electron, weight = 2.34044e-310, #alter = 0
```

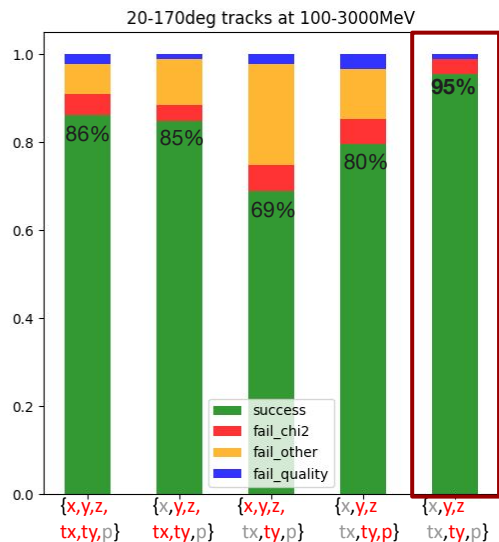

considered as matched:

vs not matched:

Current status of the matching

used for matching

simu A

simu B

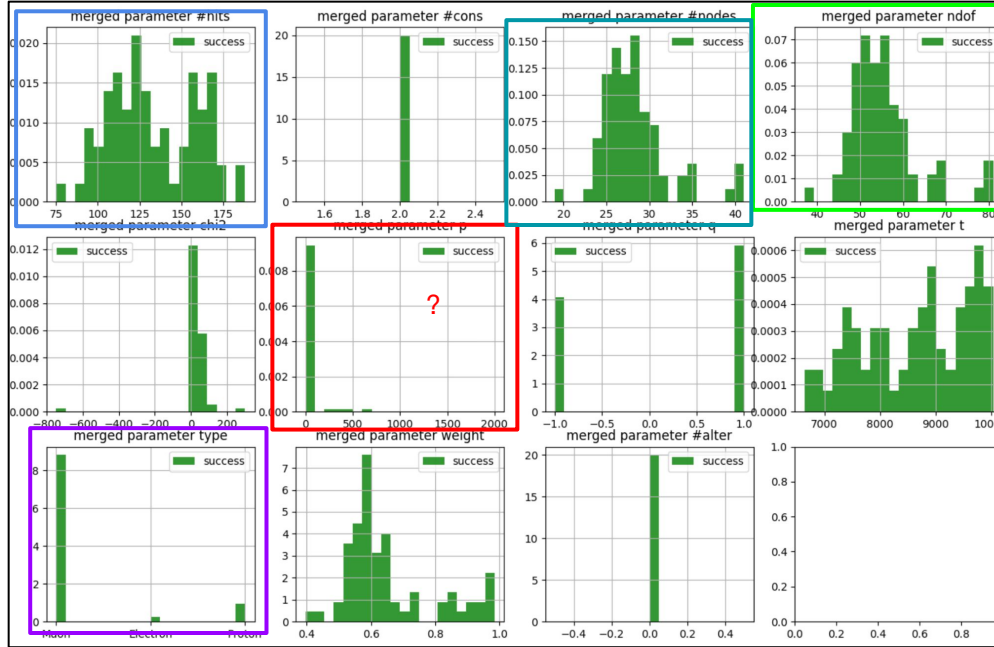

simu C

Parameters of the merged track

- merged param **p** → need to correctly check how the object states are filled and converted in hatRecon WIP

Conclusion

- Matching is better when not using x , tx and p for HAT → need to find why since we should use x , tx
- Some things were corrected in **hatRecon** which increased matching efficiency (track χ^2 , x recon...)

todo:

- look at the pos and dir parameters of the (*SFG*) and (*BottomHAT*) objects to understand why matching is better when excluding x and/or tx
- analyse the remaining failure cases, specially for the diagonal simulation
(→ check verbosity of `recPackRecon/src/TFittingUtils::FitObject()`)
- correct momentum and particle type values for the merged objects

Backup

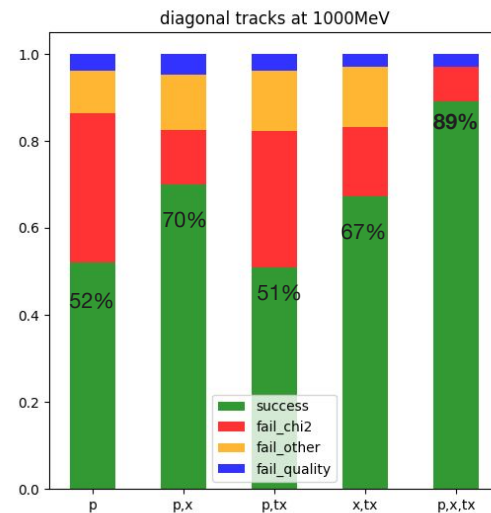

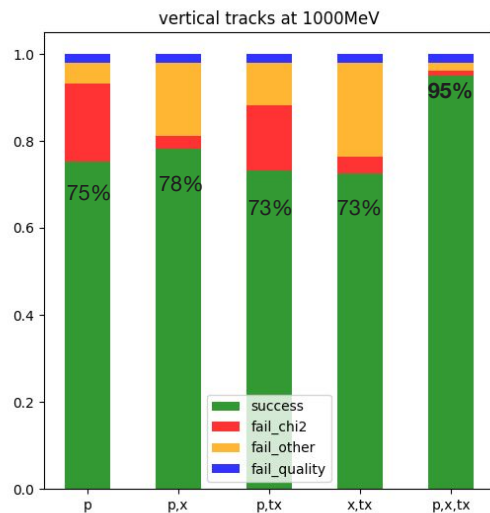

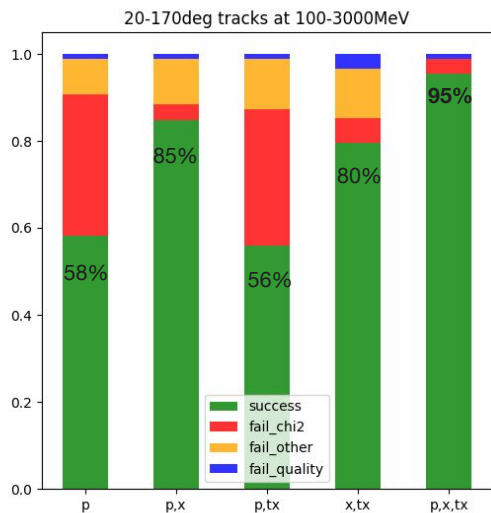

Modif in trackerRecon::TTrackerConnector

not used for matching

(before making the function)

Modif in trackerRecon::TTrackerConnector

not used for matching

when x is used for matching => low matching

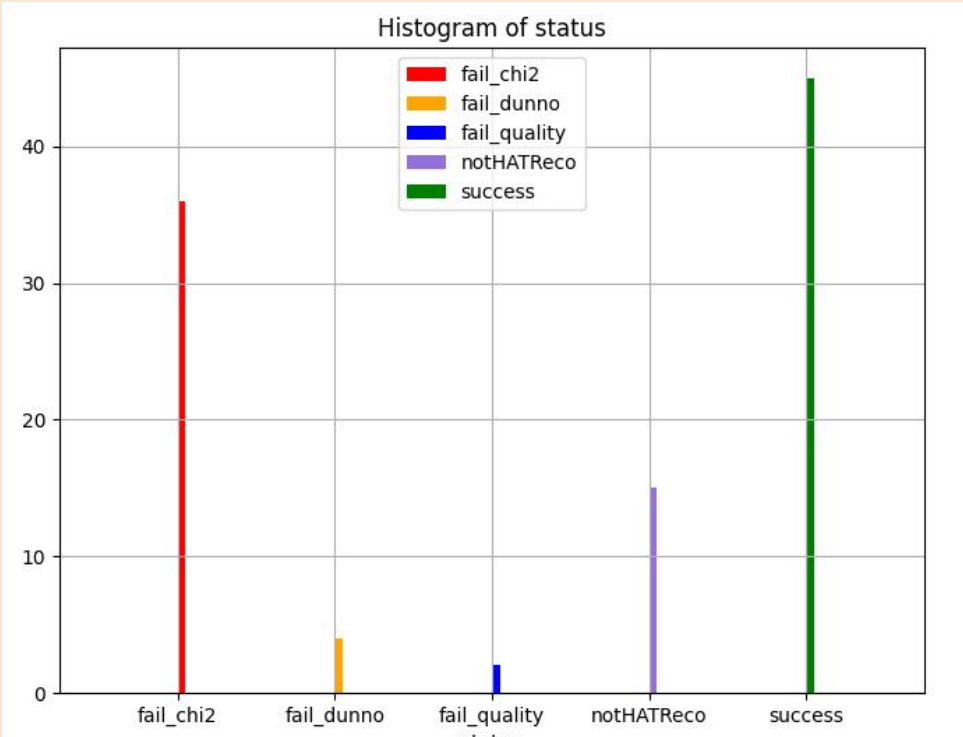

we are looking in hatRecon, seems that x reco resolution maybe worse than expected

What happens when it fails: different cases

to investigate

=> **failure case 'chi2'**
because of chi2/ndf to large?
- should we try manually decreasing it?
- some have decent chi2 but still TMergingUtils doesn't execute? → need more prints

=> **failure case unknown**
- need more prints

temporarily solved

=> **failure case 'track quality'**
- set to 1
- need investigation in hatRecon

What happens when it fails: different cases
