Towards LISA population study

Based on

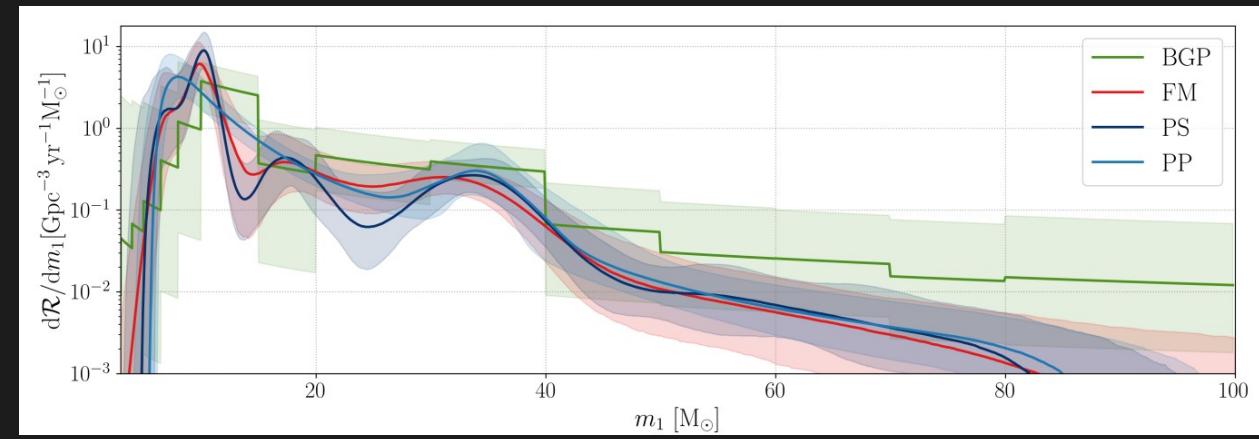

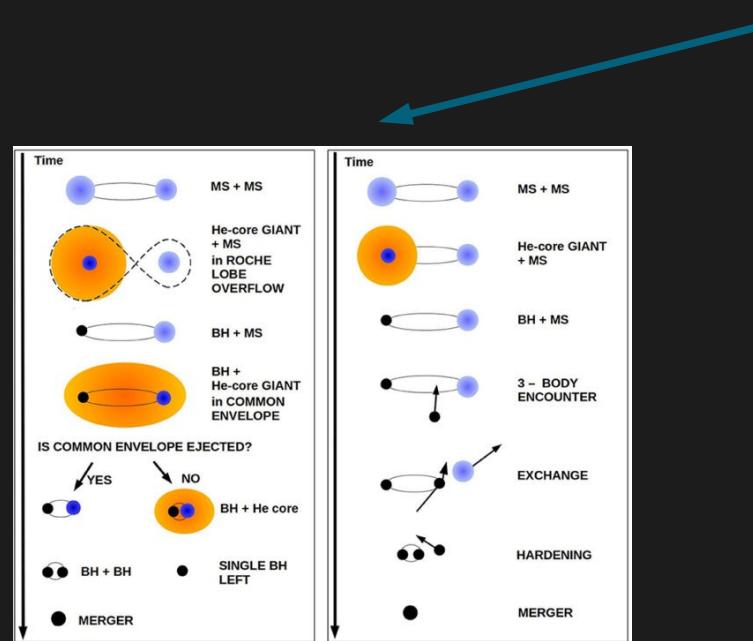

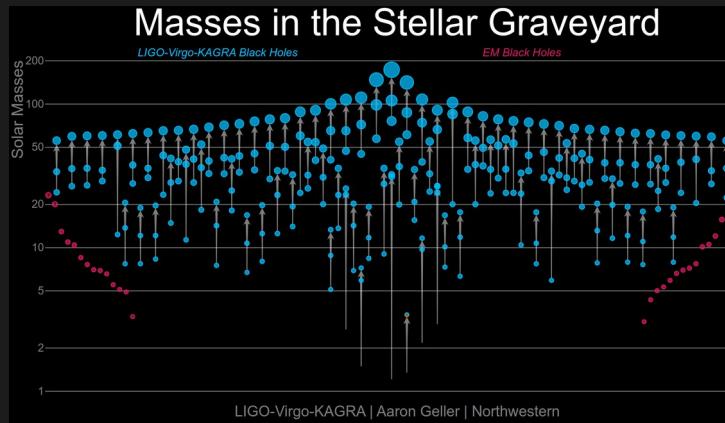

Toubiana, Karnesis, Lamberts, Miller A&A 2024

Toubiana, Sberna, Volonteri, Barausse +, in prep

Toubiana, Gair, ongoing

Santini, Karnesis, Toubiana, on going

Population studies

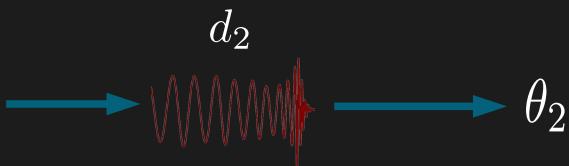

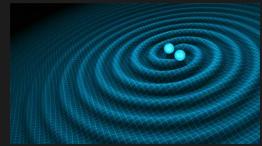

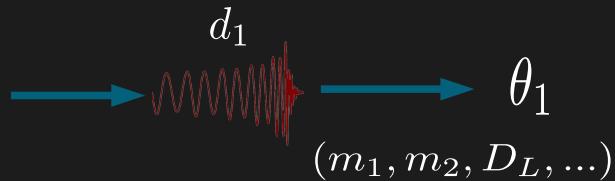

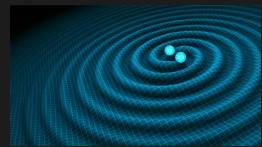

LVK, PRX 2023

Extract global properties of observations to allow the astrophysical interpretation

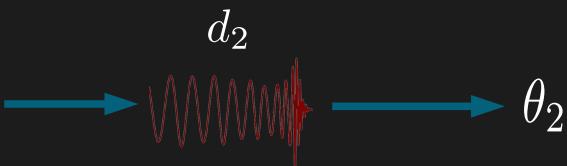

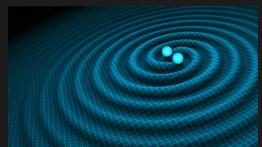

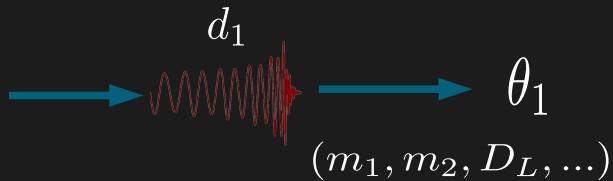

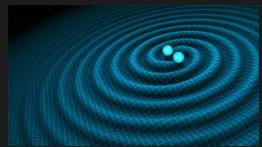

Steps for population studies

Parameter estimation

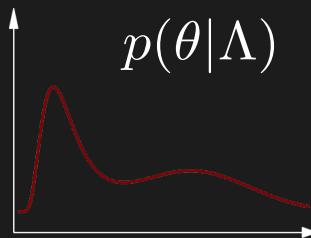

Steps for population studies

Parameter estimation

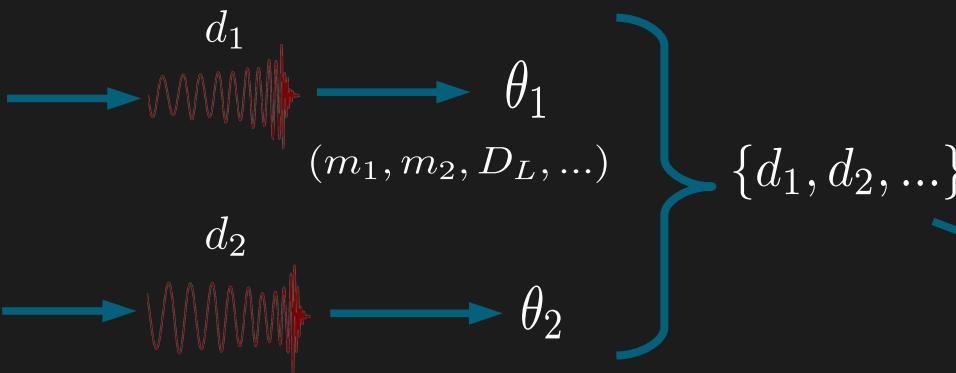

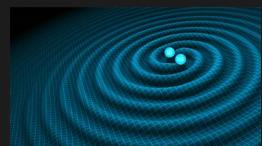

Population model

- astrophysical
- agnostic (parametric/non-parametric)

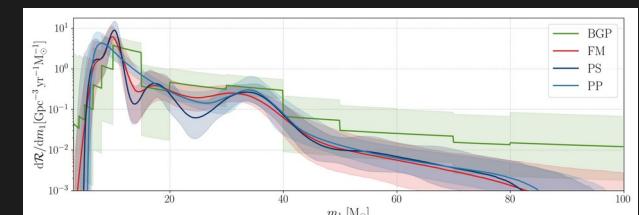

Steps for population studies

Parameter estimation

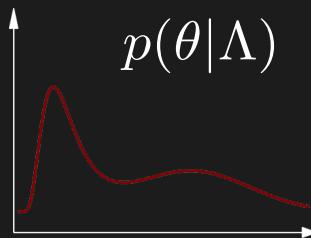

Hierarchical Bayesian analysis

$$p(\Lambda | \{d_1, d_2, \dots\})$$

Population model

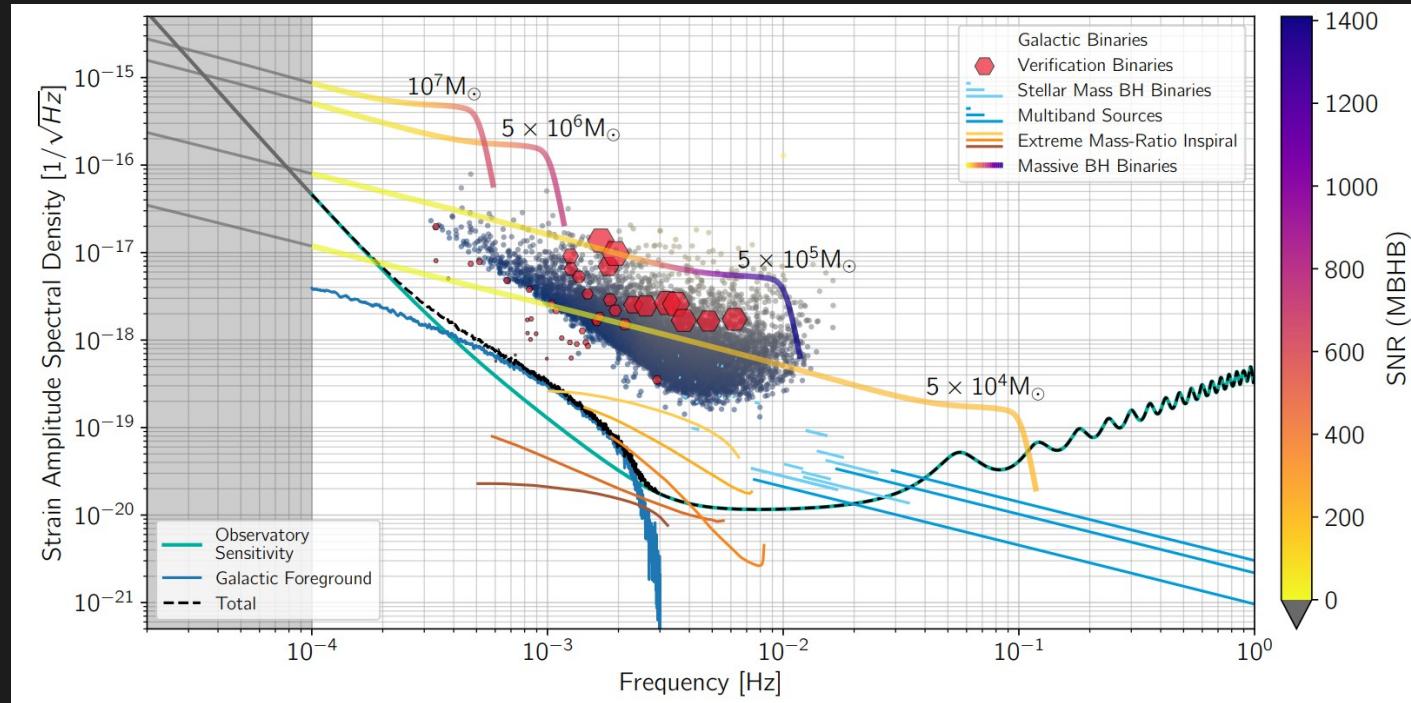

- astrophysical
- agnostic (parametric/non-parametric)

+ selection effects

LVK, PRX 2023

Challenges for LISA

LISA Redbook, 2024

- Lack of parametrised description of population of sources $p(\theta|\Lambda)$
- Need to fit data all together (Global Fit), problem for hierarchical analysis:
 - signals are not independent
 - variable number of sources
 - selection function?

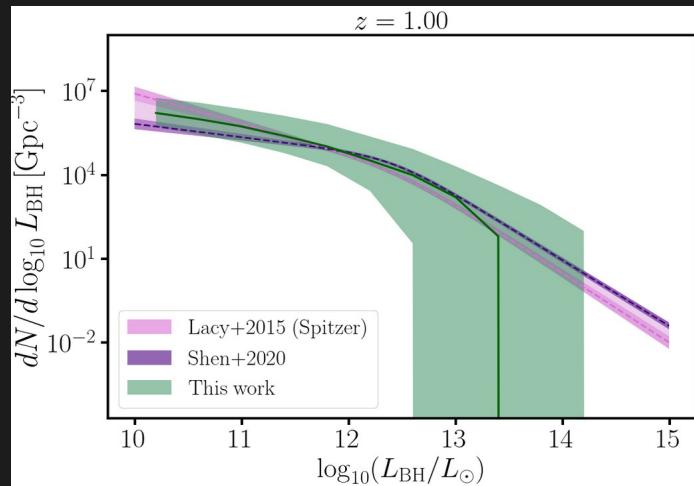

Massive black hole binaries

- Cosmological and semi-analytic models: explore impact of physical assumptions but high computational cost
- Toubiana+ PRD 2021: using a finite discrete set of model to describe the population can lead to biases
- Goal: develop a framework to describe the formation and evolution of massive black holes suited for analysing data (see also Langen, Tamanini, Marsat, Bortolas 2024)

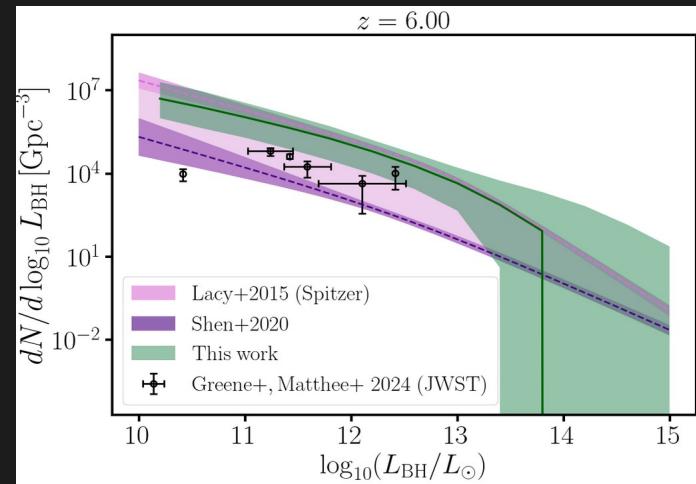

Parametric model for massive black holes⁸

- POMPOCO: Parametrisation Of the Massive black hole POpulation for Comparison to Observations
(Toubiana, Sberna, Volonteri, Barausse +, in prep)
- Describe evolution of massive black holes inside host halos using parametric prescriptions for seeding, accretion and mergers
- Assess compatibility between electromagnetic observations of massive black holes and PTA GW spectrum running full Bayesian analysis, and obtain posterior on the 12 parameters of POMPOCO

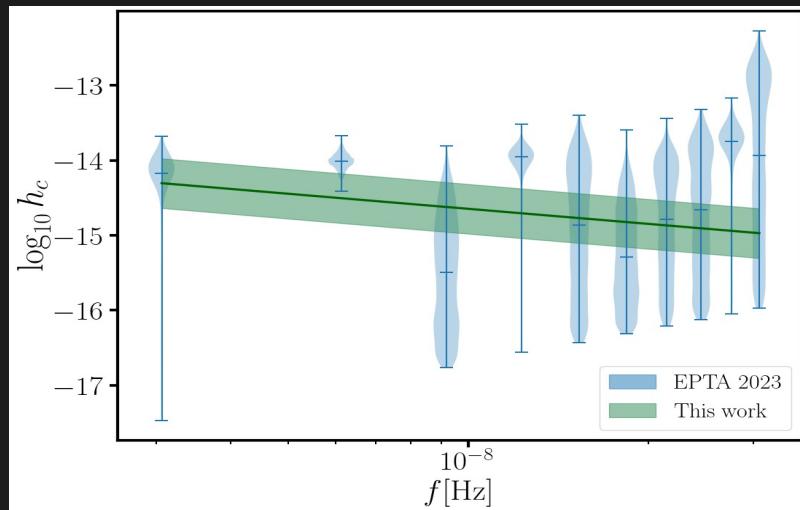

Results of POMPOCO

MBH luminosity distribution in the nearby Universe

MBH luminosity distribution in the distant Universe (JWST)

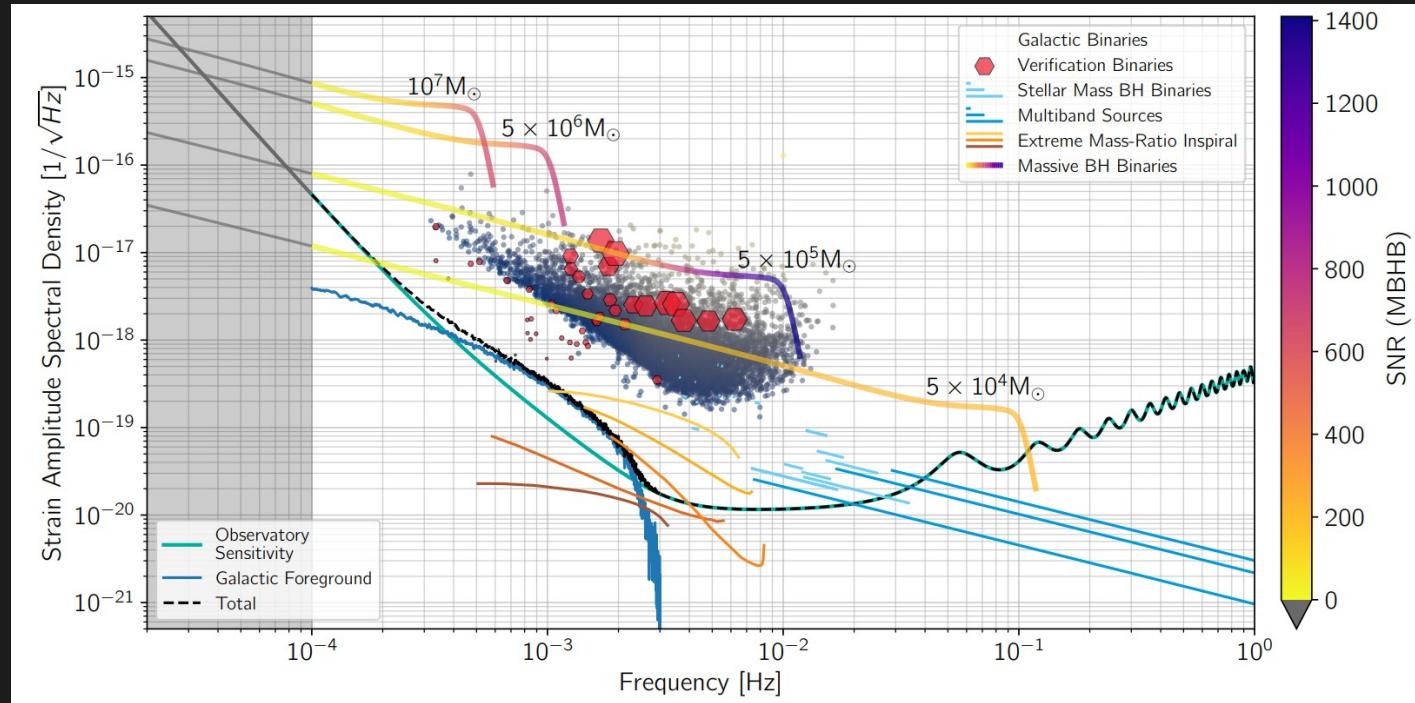

Pulsar Timing Array spectrum

Next:

- Include spins/eccentricity
- Mock LISA analysis

Double white dwarfs

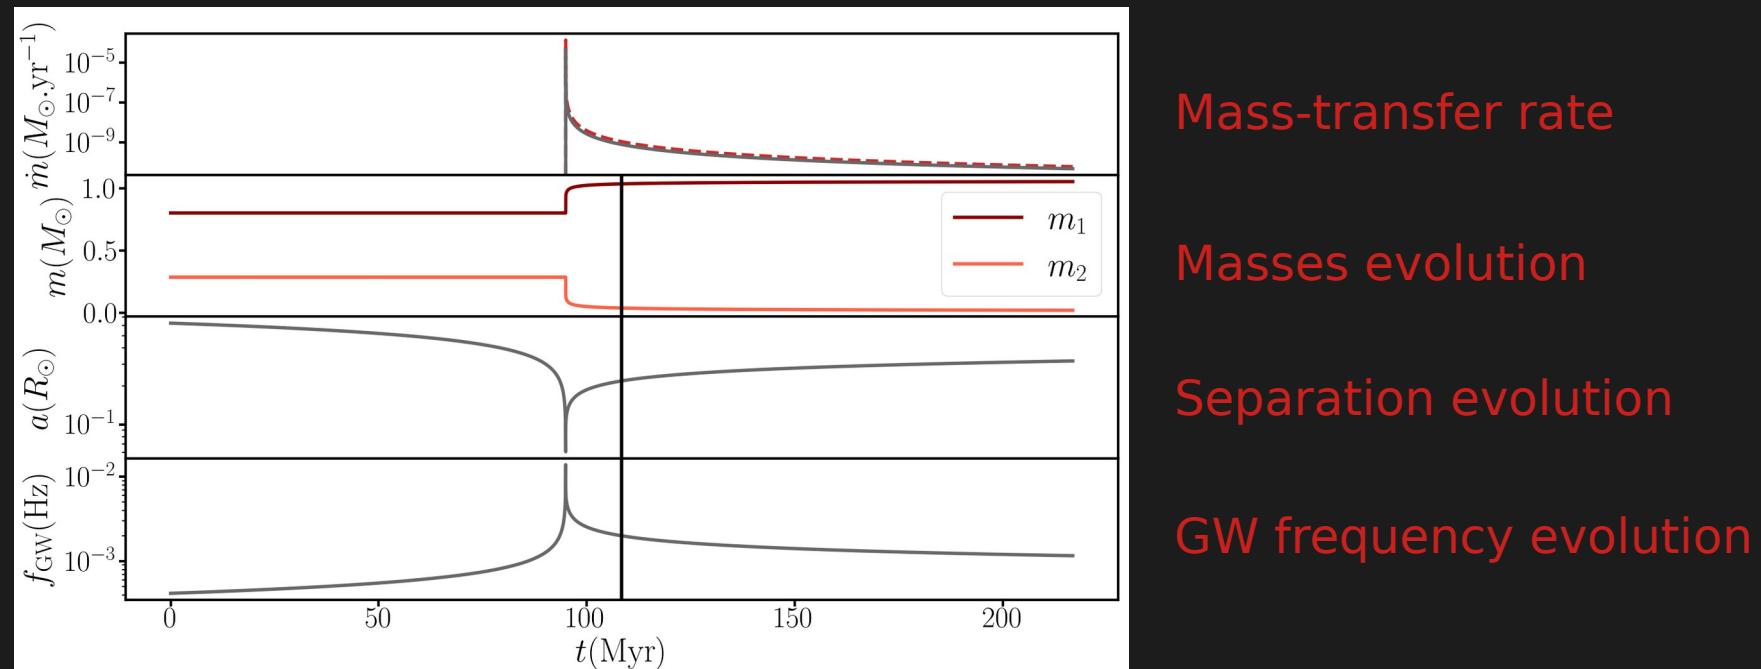

LISA Redbook, 2024

- Stochastic foreground + resolvable population
- Impact of tidal effects and mass transfer?

Toubiana, Karnesis, Lamberts, Miller A&A 2024

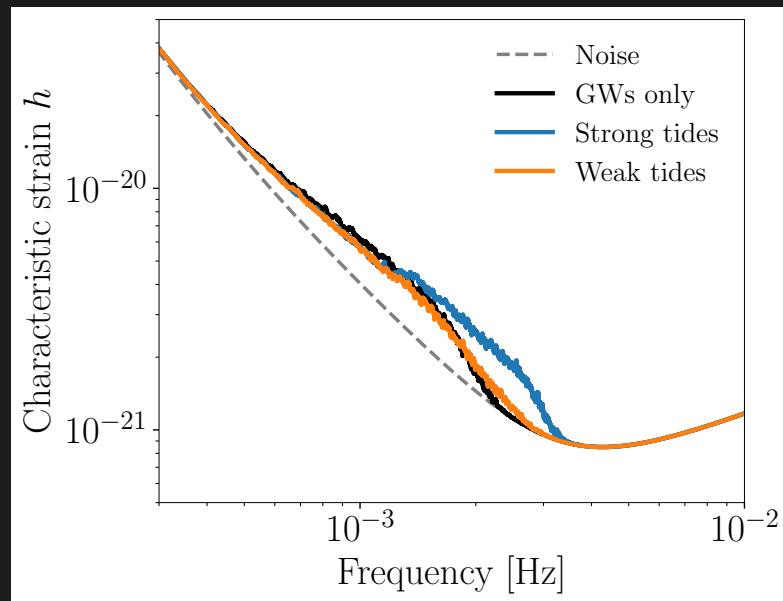

Evolution of double white dwarfs

- Semi-analytic model for the evolution of DWDs after formation (provided by Astrid's simulation)
- Includes the effect of GWs, tides, mass-transfer

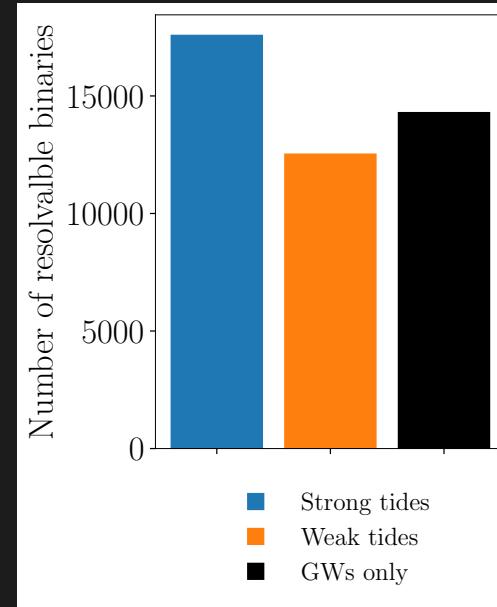

- Tides help the binaries “survive” mass transfer

Impact on LISA observations

Total noise

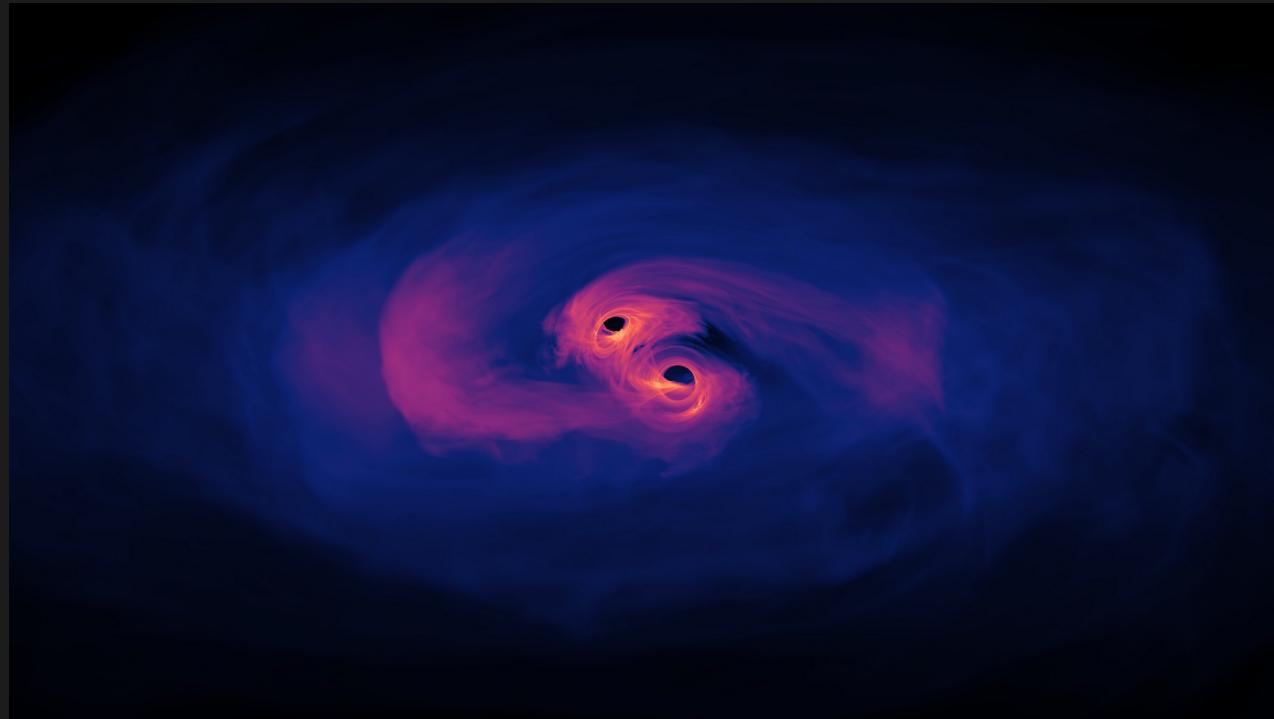

Number of resolvable sources

- Foreground can be used to measure intensity of tidal effects (Santini, Toubiana, Karnesis, on going)
- Combine foreground and resolvable sources for population study (Toubiana, Gair, on going):
 - inverse-mapping from foreground to underlying population?
 - “Selection function”?
 - confusion between populations?

Conclusions

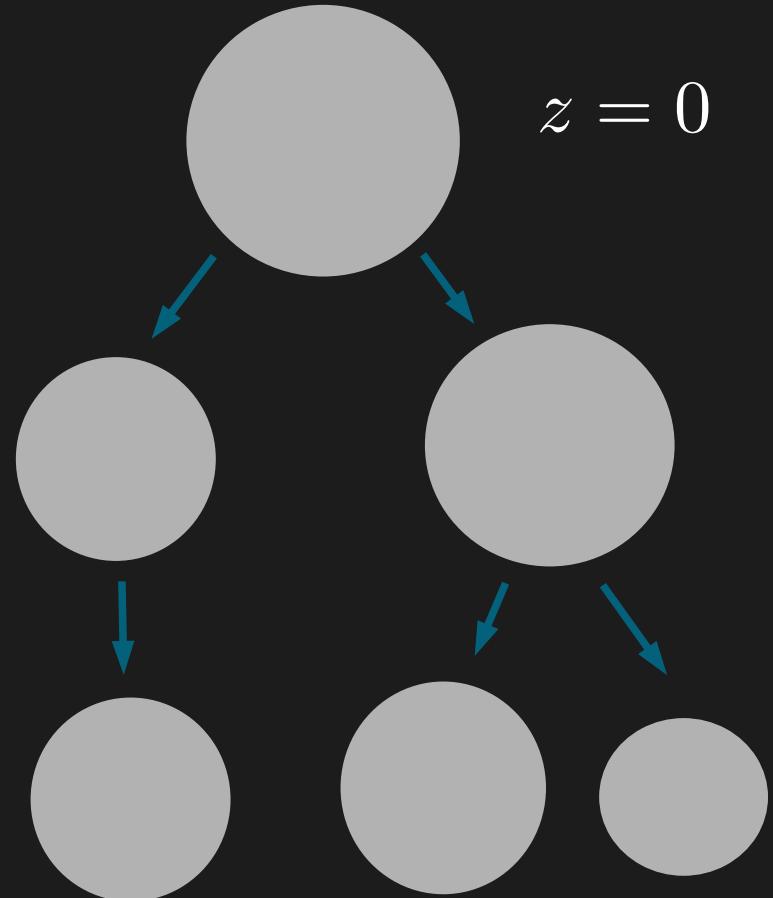

- “New” and numerous sources in LISA require new modelling and analysis techniques. Many challenges to be tackled!

Thank you for your attention!

Merger tree

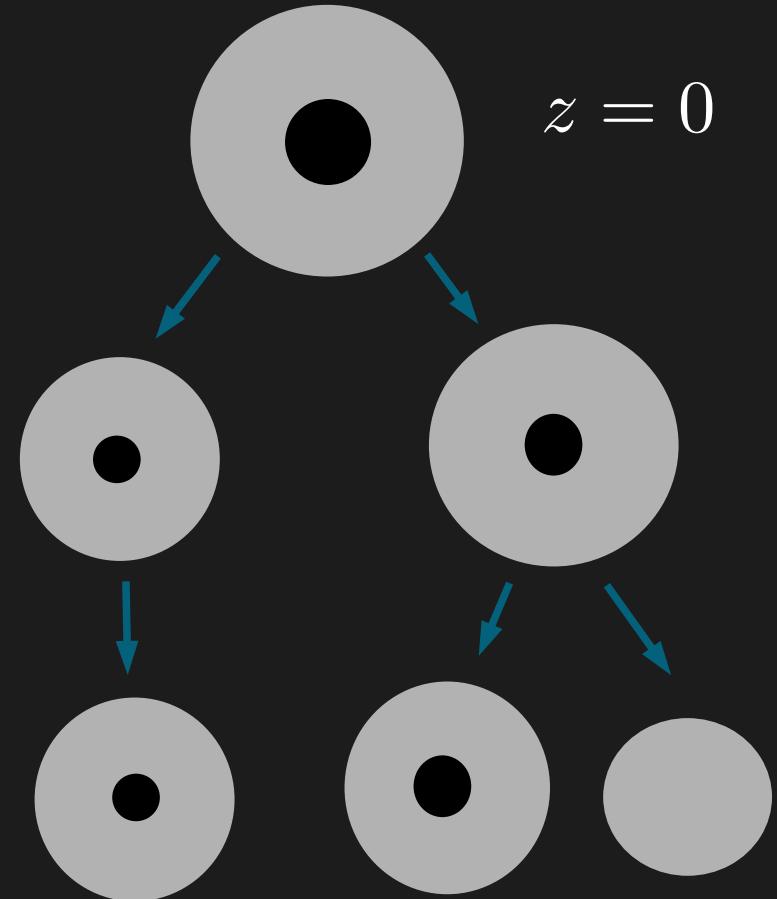

- Extended Press-Schechter
(Parkison+2007)

$z = 20$

Merger tree

- Extended Press-Schechter
(Parkison+2007)
- Evolve MBHs using
parametric prescriptions
instead of semi-analytic
ones
- Gain in computational
power

Seeding

- Seed leaf halos at $z \geq 10$ with $M_{\text{halo}} > M_{\text{cut}}$ with probability f_{BH}
- Draw mass from log-normal distribution

$$\mathcal{N}(\log(\mu_0), \sigma_m)$$

- Limit to 10% of baryonic mass of halo

Accretion

$$\dot{m} = f_{\text{Edd}}(1 - \epsilon)\dot{m}_{\text{Edd}}, \quad \epsilon = 0.1$$

- Two accretion modes:

- steady mode: draw f_{Edd} every T_{steady}

$$p(\log_{10} T_{\text{steady}}) = \mathcal{U}[10^{-3}, 0.5] \text{Gyr}$$

$$p(f_{\text{Edd}}) \propto f_{\text{Edd}}^{\gamma_{\text{steady}} - 1}, \quad f_{\text{Edd}} \in [10^{-4}, 1]$$

- burst mode: draw f_{Edd} after major halo merger ($q_h > 0.13$), valid for time t_{burst}

$$p(f_{\text{Edd}}) \propto f_{\text{Edd}}^{\gamma_{\text{burst}} - 1}, \quad f_{\text{Edd}} \in [10^{-2}, 10]$$

- Stop accretion for $z < z_{\text{cut}}$, and

$$\log_{10} m_{\text{MBH}} > \log_{10} m_{\text{MBH},0}(1 + z)^{\alpha}$$

BH mergers

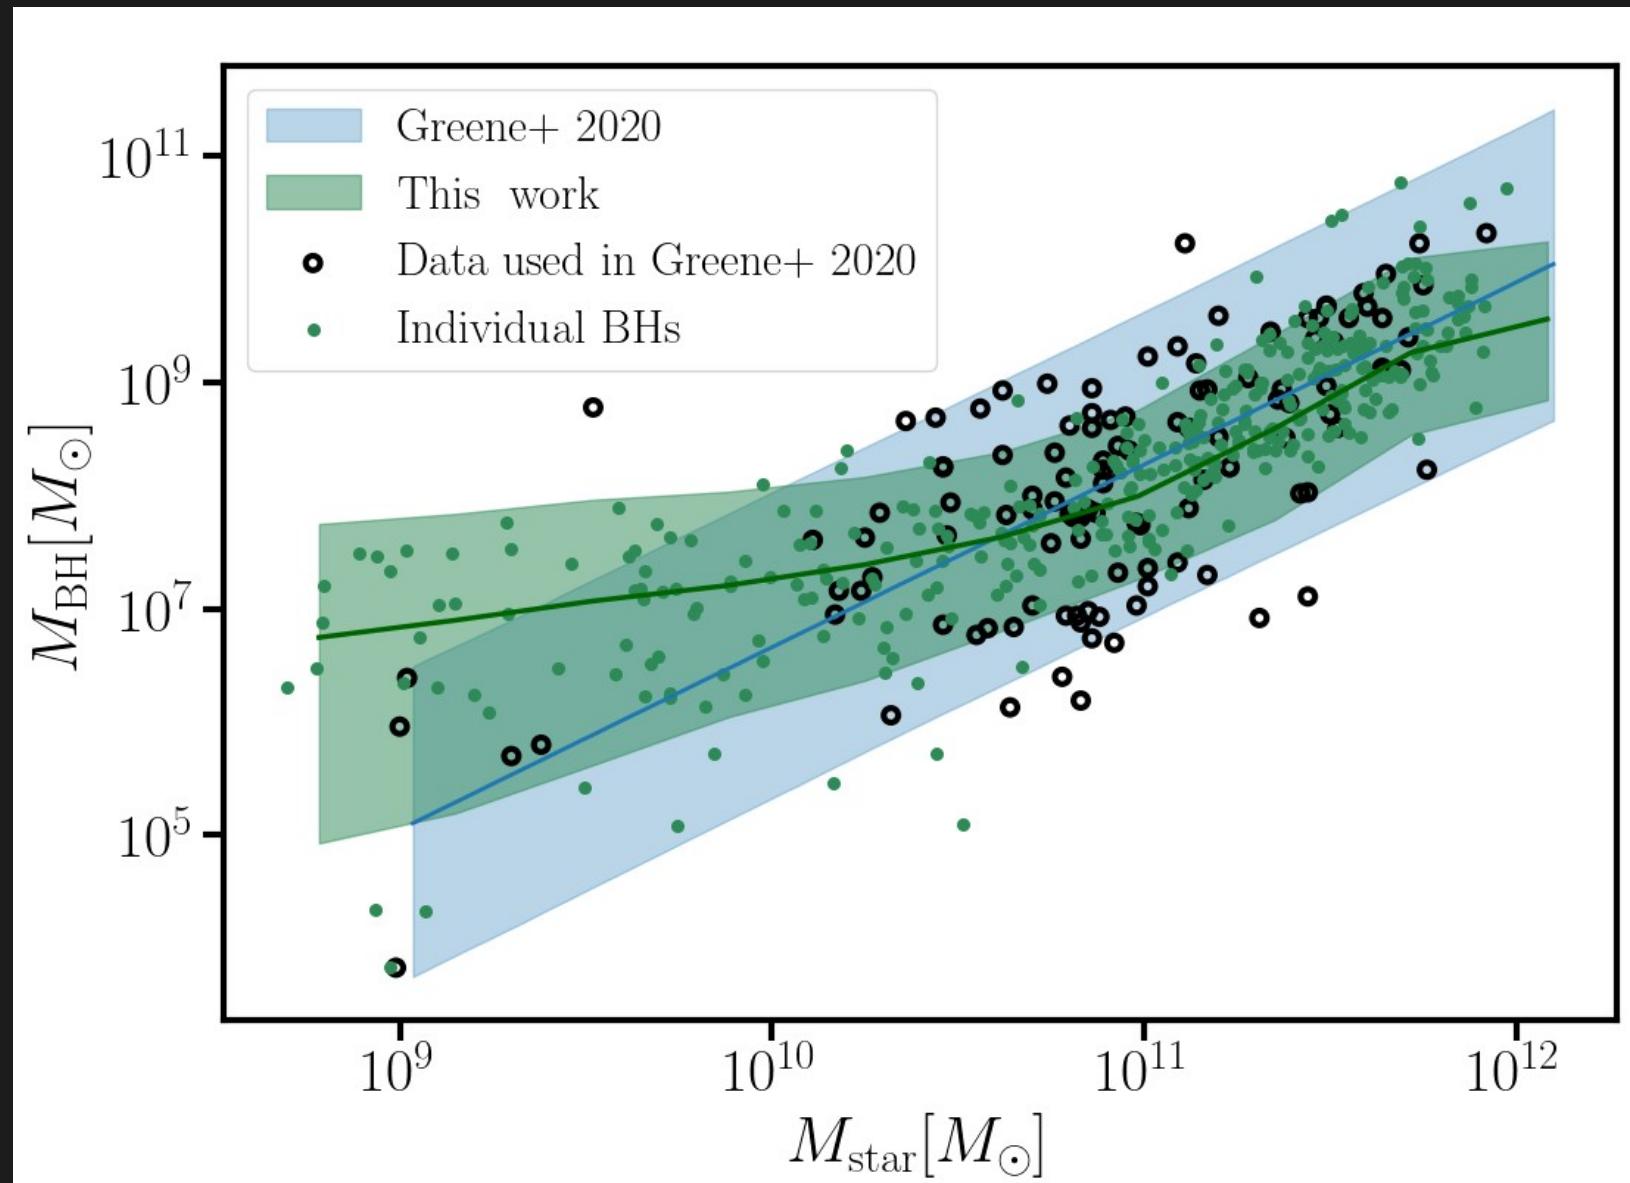

Following halo mergers:

- If major halo merger, ($q_h > 0.13$) black holes form a binary that merges after $t_{\text{dyn. fric.}} + t_{\text{delay}}$
- If minor halo merger, BHs in secondary halo sink for $t_{\text{dyn. fric.}}$ before forming a binary that merges within t_{delay}
- $t_{\text{dyn. fric.}}$ computed from Volonteri et al. 2003
- For triple/quadruple systems use results of Bonetti et al. 2018

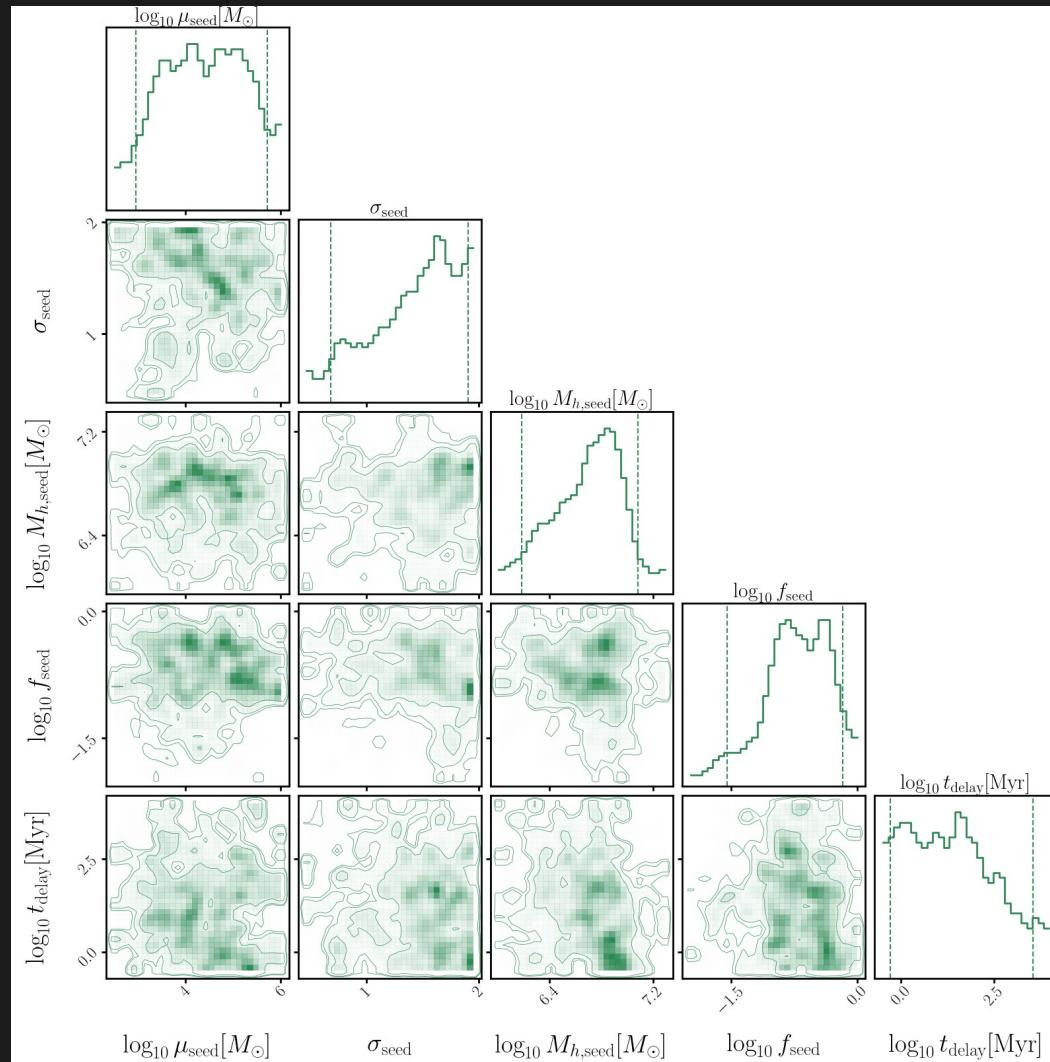

Summary of the model

- 12 free parameters:
 - seeding: $\mu_{\text{seed}}, \sigma_{\text{seed}}, M_{h,\text{seed}}, f_{\text{seed}}$
 - accretion: $\gamma_{\text{burst}}, t_{\text{burst}}, \mu_{\text{steady}}, \sigma_{\text{steady}}, z_{\text{cut}}, m_{\text{cut},0}, \alpha_{\text{cut}}$
 - Merger: t_{delay}
- ~1h to run 500 parameters
- Run MCMC to fit observations

POMPOKO

- Pompoco: Parametrisation Of the Massive black hole POpulation for Comparison to Observations ?

Evolution of double white dwarfs

- Angular momentum balance equation:

$$\dot{J}_{\text{orb}} + \dot{J}_1 + \dot{J}_2 = \dot{J}_{\text{GW}} + \dot{J}_{\text{loss}}$$

- Evolution of WD's angular momentum:

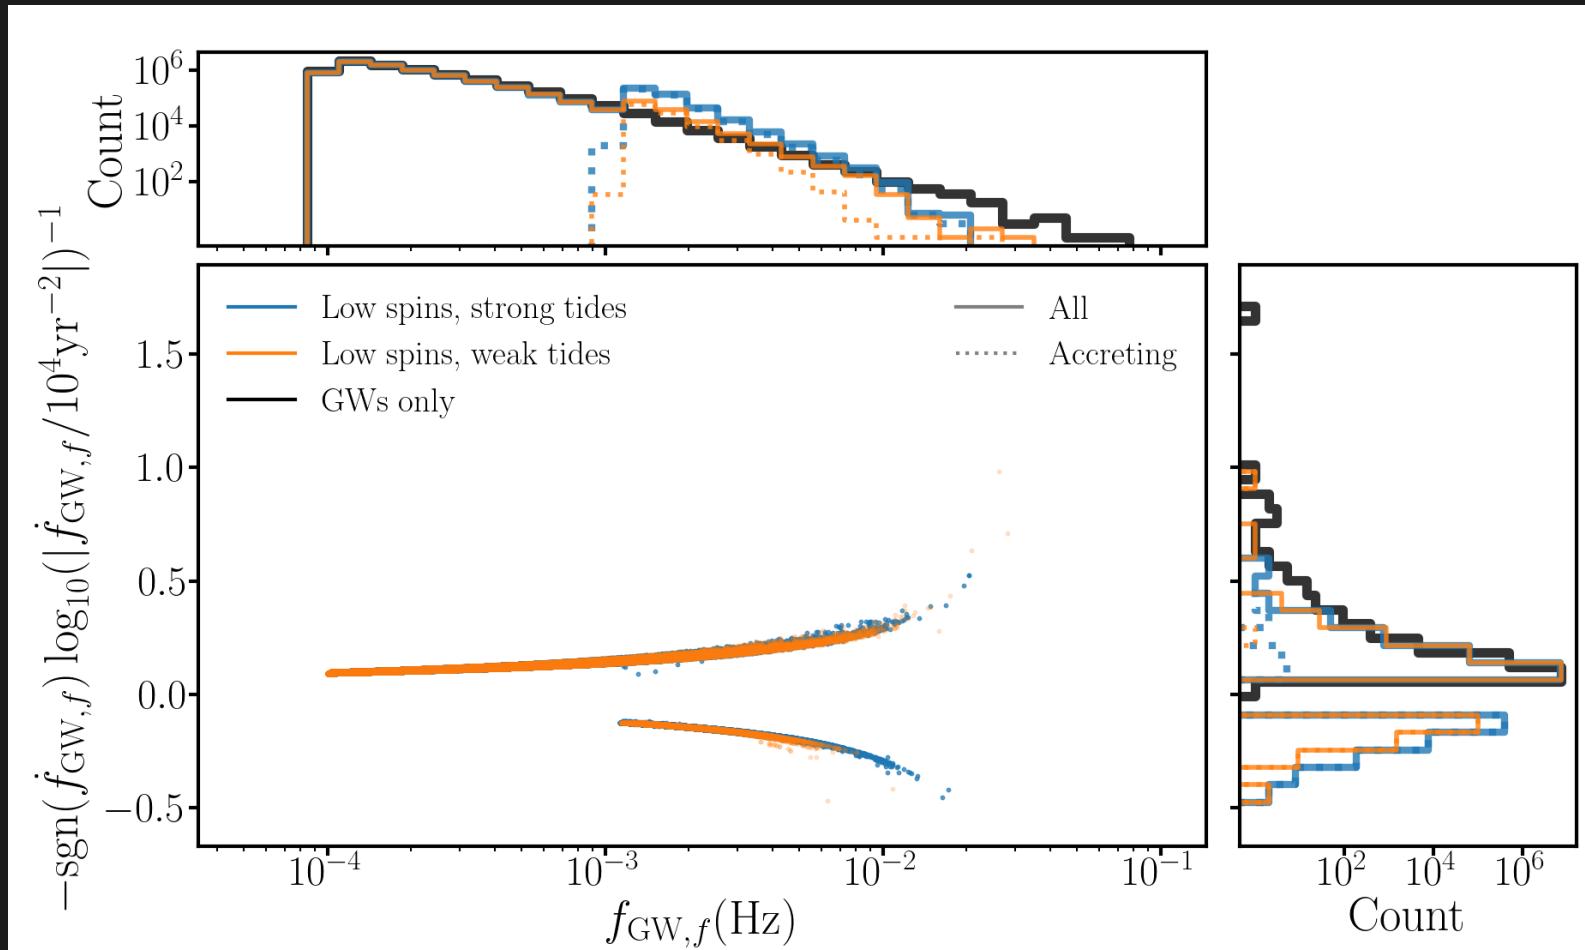

$$\dot{J}_i = j_i \dot{m}_i - \frac{I_i}{\tau_{s,i}} (\omega_i - \omega_{\text{orb}})$$

- Scaling of synchronisation timescale:

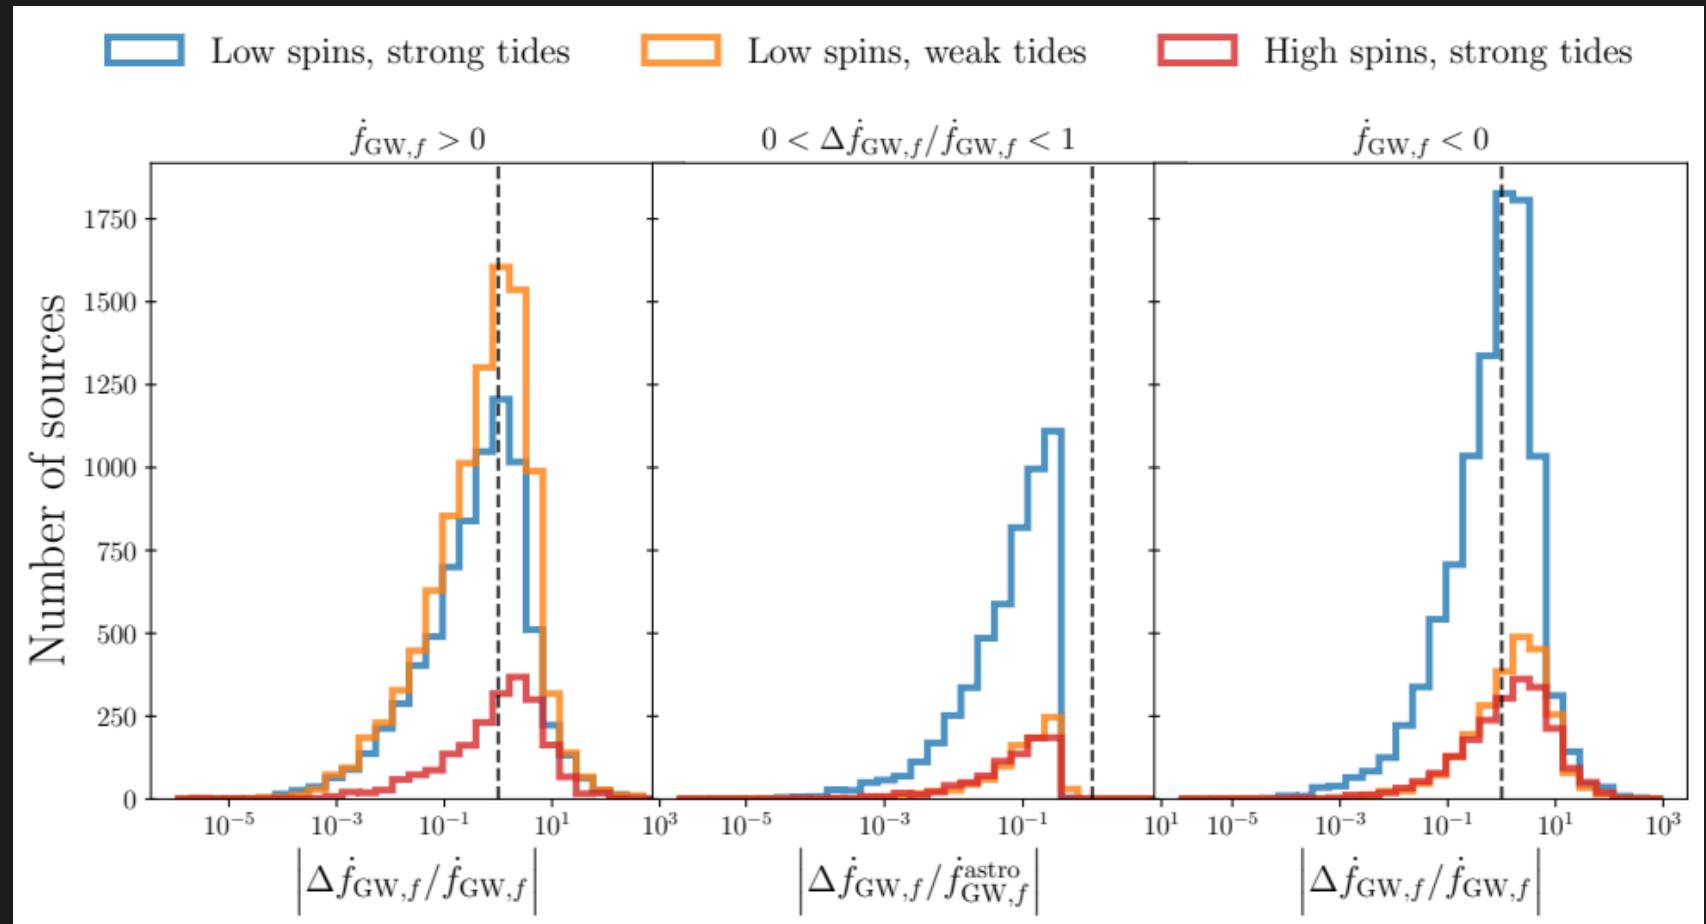

$$\tau_{s,i} \propto \left(\frac{m_i}{m_{-i}} \right)^2 \left(\frac{a}{R_i} \right)^6$$

Double white dwarf population

28

Double white dwarf population

$$\dot{f}_{\text{GW}}^{\text{astro}} = \dot{f}_{\text{GW}} - \dot{f}_{\text{GW}}^{\text{GR}}$$
