Overview- NS EOS

Current constraints

- **GW170817:** First **BNS merger with GWs provided key constraints** on the NS EOS through Λ measurements
- **Multi-Messenger Astronomy:** Combining data from observations of pulsars, nuclear experiments, and theoretical predictions has refined EOS constraints

Abbott et al. 2017, arXiv:1710.05832

2018, arXiv:1805.11581

2019, arXiv:1805.11579

Capano et al. 2020, Legred et al. 2021, Huth et al. 2022

Limitations of Current Observations

- **Low Detection Rate:** Only two **BNS mergers** (GW170817 and GW190425)
- **NS-BH Observations:** Existing **NS-BH detections provide limited tidal information** due to high mass ratios and low spins, which prevent tidal disruption signatures

Abbott et al. 2017, arXiv:1710.05832

2020, arXiv:2001.01761

Abbott et al. 2021, arXiv:2106.15163

Biscoveanu et al. 2023

Future Observing Prospects

- **O5 Observing Run:** Upgraded LVK network is expected to **increase the detection range** for BNS mergers
- **Next-Generation:** Precision constraints on NS matter will likely require future observatories (ET, CE, ...)

Abbott et al. 2018, arXiv:1304.0670

Maggiore et al. 2020, Evans et al. 2021

Chatziioannou 2020, arXiv:2006.03168v2

Aim: Constraining NS EOS with LVK Network in A+

Objectives

- **Assess how well we can constrain NS EOS** recovery using simulated BNS mergers detectable by LVK Network
- **Compare different EOS models:** soft (**hqc18**), intermediate (**sly230a**), and stiff (**mpa1**), under realistic observation scenarios
Baym et al. 2018 *Chabanat et al. 1997,*
Danielewicz and Lee 2009, *Müther et al. 1987*
Gulminelli and Raduta 2015

Methodology

- **Simulate BNS Populations:** Inject large number of BNS events (**1,000 events per EOS**) into A+ sensitivity
- **Parameter Estimation:** Use ROQs for rapid GW signal analysis in the LVK network *Canizares et al. 2015,*
- **Constrain EOS:** Apply Bayesian inference to extract EOS constraints *Smith et al. 2016*

EOS Inference Approach

- **Post-process Parameter Estimation:** Use spectral EOS inference with large prior sets
- **Sequential Inference:** Combine EOS information across events, using posteriors from one event as priors for the next

Determine how well the injected EOSs are recovered in all scenarios, based on the number of detected BNS events

Sensitivity curves used

Methodology Overview: Simulations of GWs

Injection Setup

Landry and Read 2021, arXiv:2107.04559

Abbott et al. 2023, arXiv:2111.03634

- **BNS Population Model:** Uniform NS mass distribution with random pairing, low spin scenario and sources up to 460 Mpc (comoving volume)
- **Equation of State (EOS) Models:** Tidal deformability (Λ) determined by mass using $\Lambda(m)$ relation
- **Waveform:** Use **IMRPhenomPv2_NRTidalv2** model for 128s and 256s signals

Muthur et al. 1987, Reinhard and Flocard 1995, Baym et al. 2019

Dietrich et al. 2019

Parameter (Symbol) [Unit]	Injection configuration	Parameter estimation prior
Source-frame primary NS (m_1) [M_\odot]	Uniform [$1, m_{\max}^*$] with $m_1 \geq m_2$	Determined by \mathcal{M}_c and q
Source-frame secondary NS (m_2) [M_\odot]	Uniform [$1, m_{\max}$]	Determined by \mathcal{M}_c and q
Source-frame chirp mass (\mathcal{M}_c) [M_\odot]	$\frac{(m_1 m_2)^{3/5}}{(m_1 + m_2)^{1/5}}$	Uniform [1.6, 2.6] M_\odot for 128 s Uniform [0.98, 1.7] M_\odot for 256 s
Source-frame mass ratio (q)	m_2/m_1	Uniform [0.125, 1]
Dimensionless primary NS spin (a_1)	Uniform [0, 0.05]	Uniform [0, 0.05]
Dimensionless secondary NS spin (a_2)	Uniform [0, 0.05]	Uniform [0, 0.05]
Primary NS tilt (θ_1) [radian]	Uniform Sine [0, π]	Same as injection
Secondary NS tilt (θ_2) [radian]	Uniform Sine [0, π]	Same as injection
Relative spin azimuthal angle (ϕ_{J1}) [radian]	Uniform [0, 2π]	Same as injection
Spin phase angle (ϕ_{12}) [radian]	Uniform [0, 2π]	Same as injection
Luminosity distance (d_L) [Mpc]	Uniform in square [10, 460] Mpc	Square power law [1, 1000] Mpc
Right ascension (α) [radian]	Uniform [0, 2π]	Uniform [0, 2π]
Declination (δ) [radian]	Uniform Cosine [$-\pi/2, \pi/2$]	Uniform Cosine
Inclination angle (θ_{JN}) [radian]	Uniform Sine [0, π]	Uniform Sine [0, π]
Polarization (Ψ) [radian]	Uniform [0, π]	Uniform [0, π]
Coalescence phase (ϕ) [radian]	Uniform [0, 2π]	Marginalized
Geocenter time (t_c) [second]	Trigger time	Uniform [trigger time - 0.1, trigger time + 0.1]
Tidal deformability of primary NS (Λ_1)	Determined by m_1 and EOS	Uniform [0, 5000]
Tidal deformability of secondary NS (Λ_2)	Determined by m_2 and EOS	Uniform [0, 5000]

Methodology Overview: PE and EOS Inference

Parameter Estimation of GWs from BNS Mergers

Qi and Raymond 2020, Soichiro et al. 2023, Ashton et al. 2019

- **Technique:** Apply **ROQ-accelerated PE using Bilby** (1000 events PE completed in 6 days)
- **Detection Thresholds:** Events detectable with **SNR > 11.2** in the LVK network at O5 sensitivity (around 600-700 events for each EOS)
- **Recovered Parameters:** Full parameters, including mass and tidal deformability distributions derived for each event (*priors used for PE detailed in a previous table*)

EOS Inference

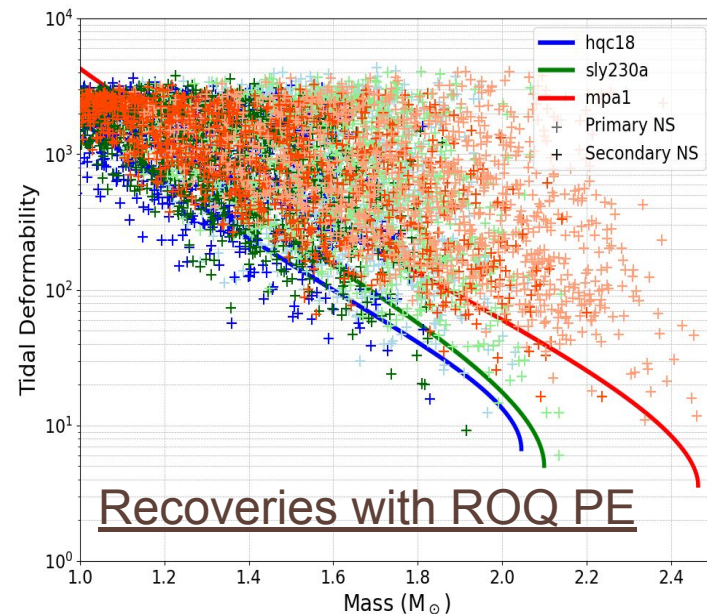

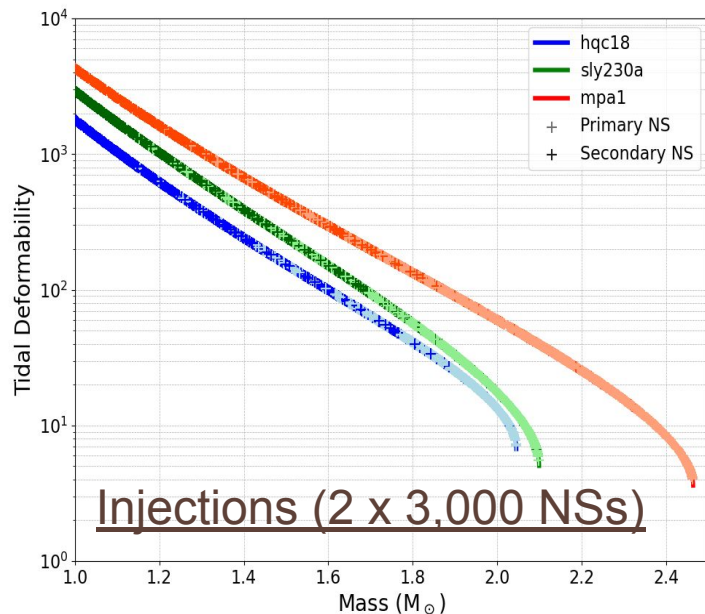

Landry et al. 2020, Legred et al. 2021

- **Bayesian Framework:** **Hierarchical Bayesian inference** using lwp software (EOS modeled as a Gaussian process based on 10,000 EOS samples)
- **Likelihood Calculation:** EOS likelihood calculated for each GW event, integrating over mass and tidal parameters / Selection effects considered, but independent of tidal deformability
- **Expected Results:** Constraints on EOS parameters and NS observables (e.g., NS radius, pressure at saturation density)

10k EOSs as prior for EOS constraints

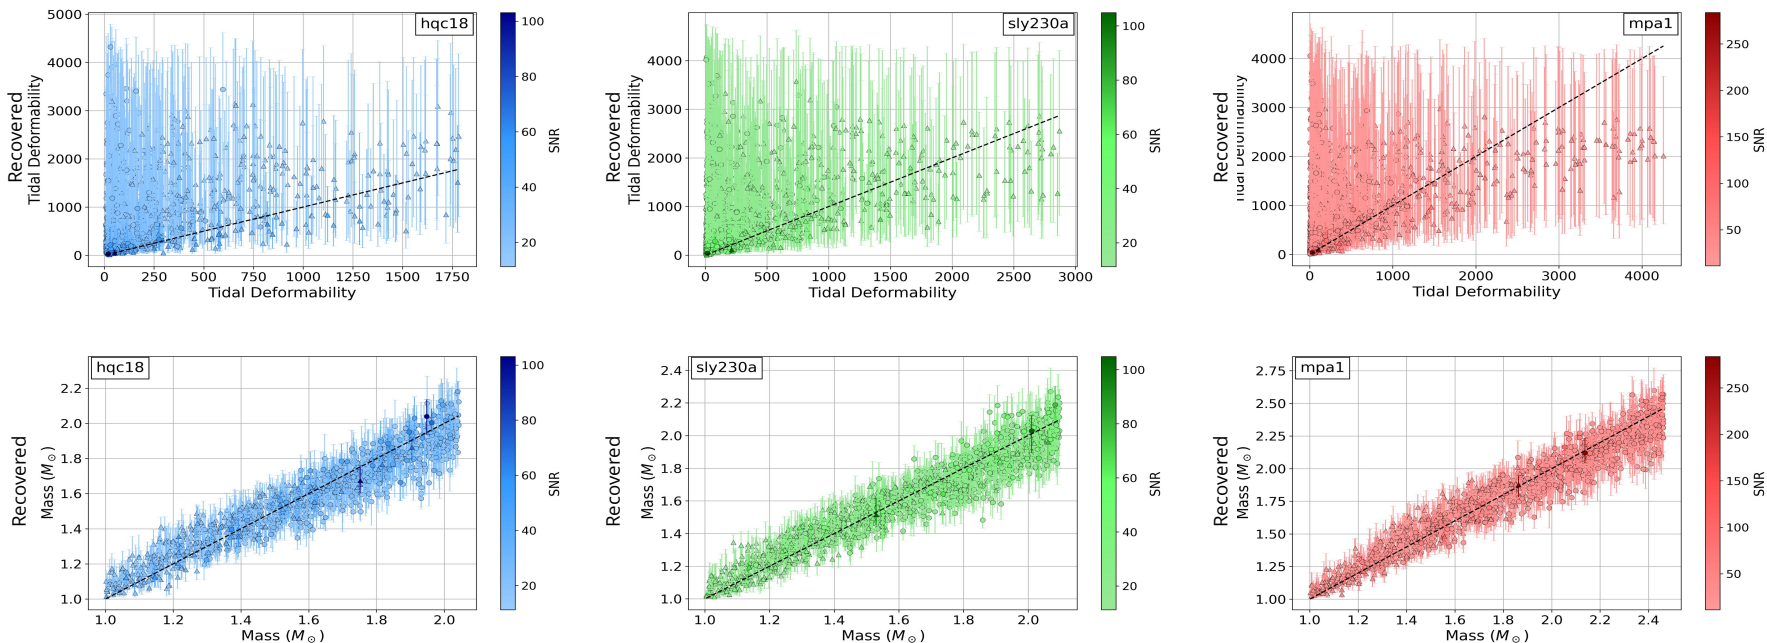

Distribution of Mass and Tidal Deformation

- **Injected vs Recovered values:** good coverage of the mass- Λ parameter space, posteriors cluster tightly
- **After ROQ PE:** Distinguishing EOS models is visually difficult

Medians and Error Bars of Recovered Injections

- **Tidal Deformability:** Spread uncertainties, overestimation at low Λ and underestimation at high Λ
- **Mass:** Injected vs. posterior masses align well for all EOS models, with small errors and good accuracy
- **Impact on EOS Recovery:** Biases in the Λ -mass relationship due to systematic errors in Λ estimates

EOS Constraints with Different Numbers of Detections

Combined posteriors for the three EOS for two different size groups (10 and 20 events) + averaging

All EOS show biases, even for groups of 10 events. Bias increases with larger group sizes.

EOS Constraints Varying w.r.t. Chirp Mass Ranges (1/2)

Combined posteriors for the three EOS for different chirp mass ranges considering only the **15 loudest events** in groups of 30 + averaging

$N_{\text{eff}} > 100$

$M_c \in [1.0, 1.2] M_{\text{sun}}$

$M_c \in [1.2, 1.4] M_{\text{sun}}$

EOS Constraints Varying w.r.t. Chirp Mass Ranges (2/2)

Combined posteriors for the three EOS for different chirp mass ranges considering only the **15 loudest events** in groups of 30 + averaging

$N_{\text{eff}} > 100$

$M_c \in [1.4, 1.6] M_{\text{sun}}$

hqc18 is well recovered. sly230a and mpa1 show biases, especially at lower masses.

$M_c \in [1.6, \text{Max}] M_{\text{sun}}$

- **Tidal Deformability Bias:** Underestimation at low masses and overestimation at high masses
- **Method Limitations:** Recovery varies by EOS and mass range, better performance at higher M_c

Evolution of EOS Constraints: N Loudest Events (1/3)

Check out the videos showing how the constraints evolve as we include more loudest events for each EOS model

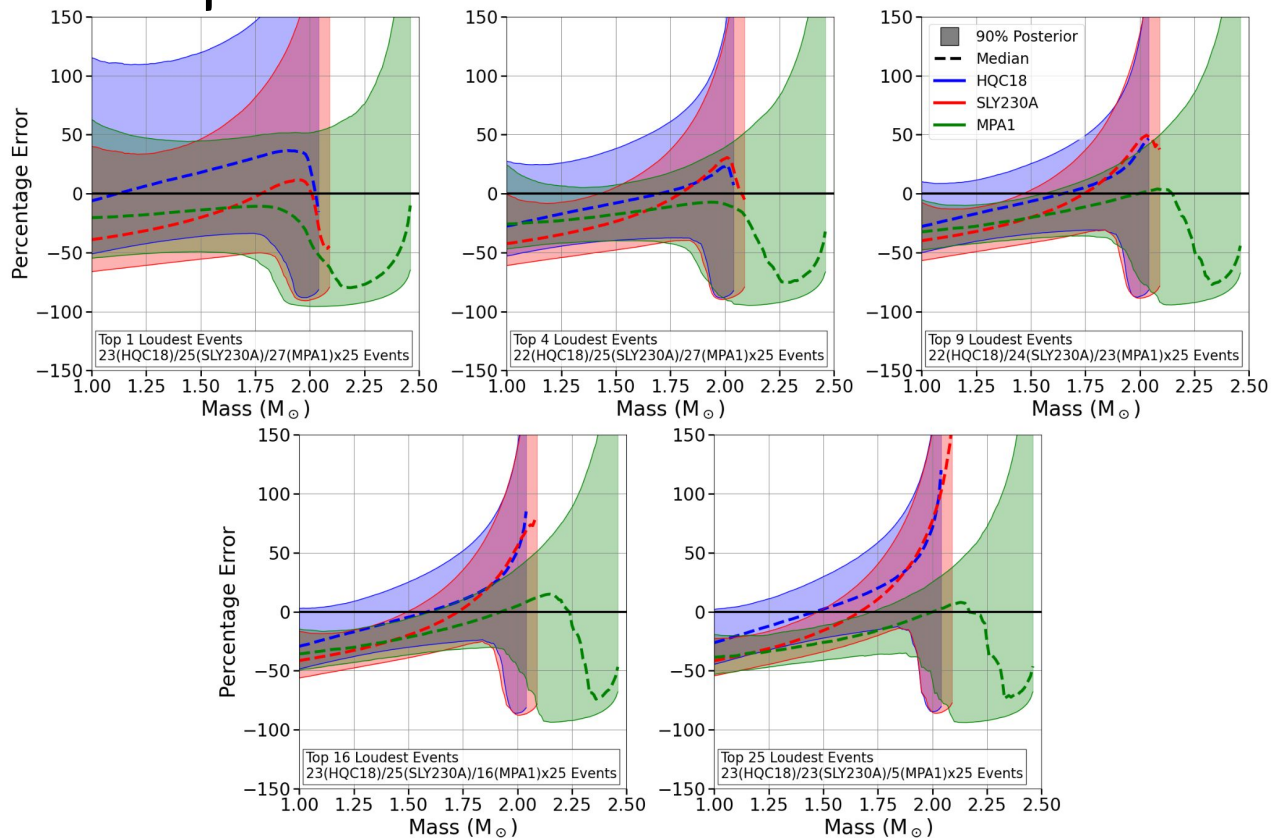

Watch the videos
[here!](#)

Evolution of EOS Constraints: N Loudest Events (2/3)

$N_{\text{eff}} > 100$

Evolution of EOS Constraints: N Loudest Events (3/3)

$N_{\text{eff}} > 100$

Conclusions

- **EOS Recovery with O5 LVK Network:** Simulated BNS mergers show **promising constraints on NS EOS**, especially with more massive systems
- **Biases in Tidal Deformability:** Systematic underestimation at low masses and overestimation at high masses affects accurate EOS recovery (need to take it into account + might be interesting to find out the reasons)
