					GAUGE BOSONS

- The Standard Model (SM) of particle physics consists of 4 types of particles:
 - Quarks
 - Leptons
 - Gauge Bosons
 - The Higgs Boson
- At the **LHC** we collide protons which break apart upon interactions of the constituent quarks
- This results in collimated sprays of particles known as **Jets**

Hadronisation and Jets

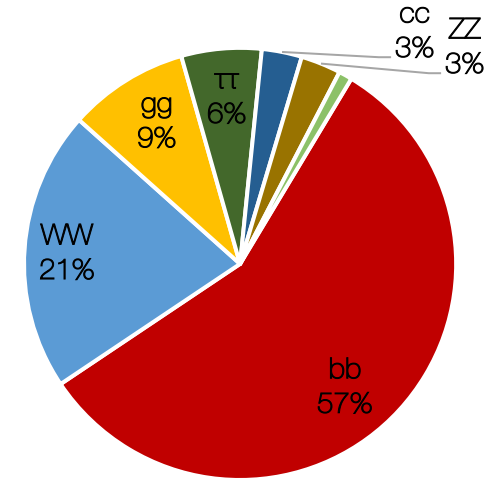

- Quarks experience **Colour Confinement** – pairs of quarks act springs, it takes energy to pull them apart. Eventually the energy is so great two new pairs form
- The resultant hadrons interact slightly differently depending on which type of quark it is made of, the process of identifying this is called **Flavour Tagging**

Flavour Tagging at Hadron Colliders

- Hadron colliders produce *a lot* of jets – the vast majority are produced from light flavour quarks
- Being able to identify heavy flavour jets is crucial for a wide range of interesting events e.g. $H \rightarrow bb/cc$ and $t \rightarrow Wb$

SM 125 GeV Higgs Decays

Physics of b-jets

- **B-hadrons** are relatively long lived and travel a measurable distance before decaying
- This creates multiple distinct vertices where charged particles originate from
- Secondary vertices will have a high mass – b-quark mass is significantly larger than light flavours
- High momentum muons are frequently found within the jet as well

Particle Transformer for Jet Tagging

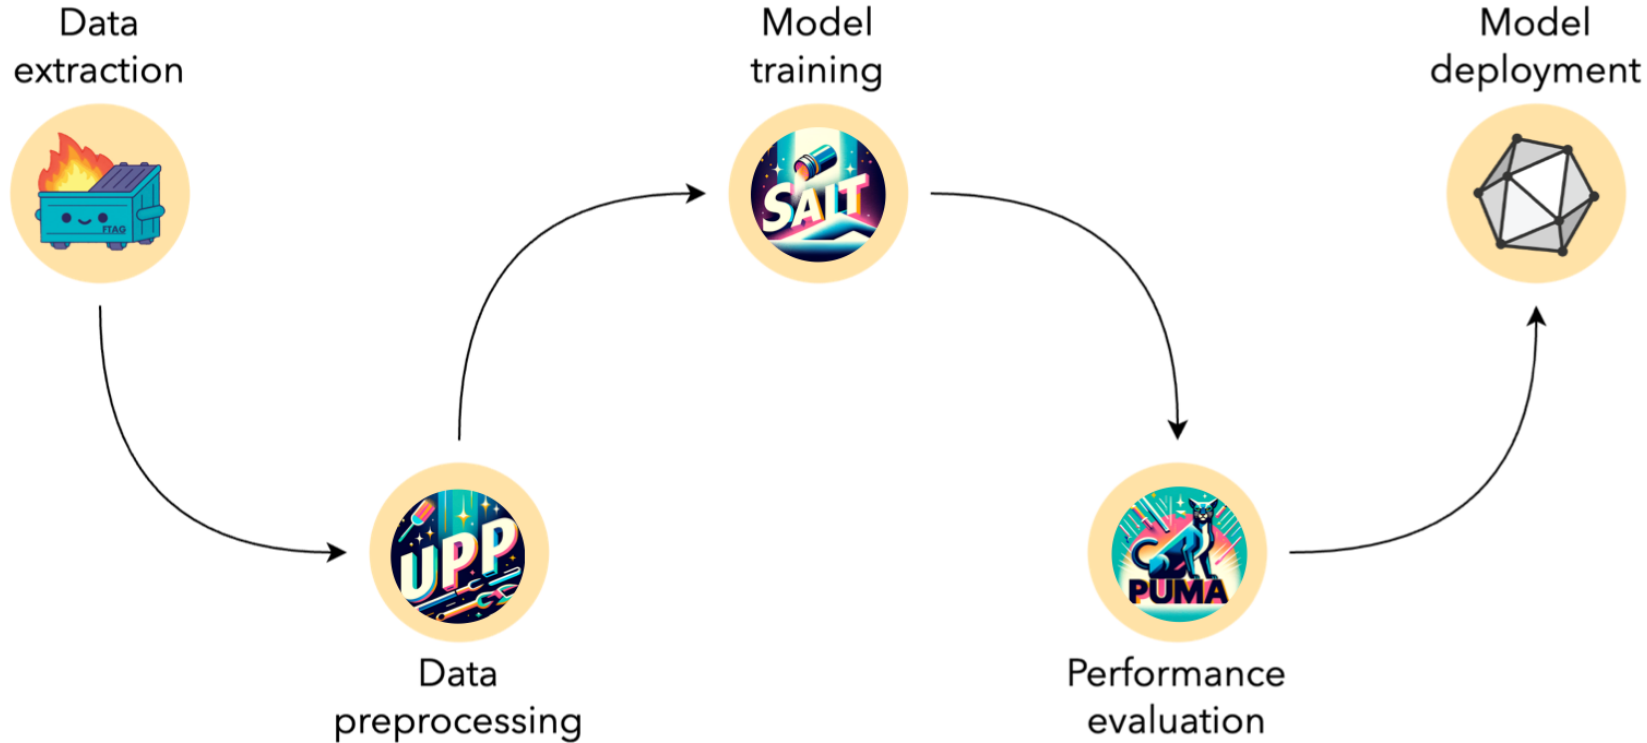

Huilin Qu¹ Congqiao Li² Sitian Qian²

Transformer Based Flavour Tagging

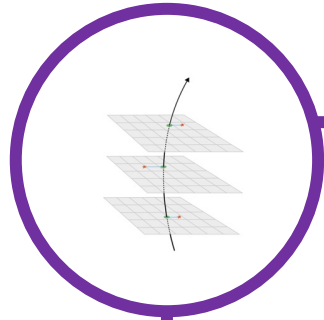

- The current generation of flavour tagging model used in ATLAS, called [GN2](#), is a transformer based model
- Multiple input modalities are used and trained to do multiple different physics tasks

ML Pipeline

- Current models use in the regime of 100's of millions of training data points – a single training event contains $O(100)$ constituents with $O(20)$ features each. Models have up to $O(10\text{ m})$ parameters currently
- Multiple packages developed for the extraction, processing and training of models using ATLAS data (Salt training framework [under review in JOSS](#))

Heterogeneous Inputs

Tracks

- Left by charged particles going through inner detector
- Information on trajectories, hits in layers etc
- Neutral particles **don't** interact

Calorimeter

- Measures energy of particles
- Complements tracker information for charged particles
- Neutral particles **do** interact

Leptons

- Electrons and muons are built from combining information from other parts of the detector
- Muons leave tracks in a dedicated muon spectrometer

- We have information from multiple different sub-detectors and reconstructed objects that can be used
- Different input types vary in both feature dimensions and multiplicity

Heterogeneous Inputs

- In general, the more information we include the better the performance we see
- Still many open questions on how best to utilise different modalities – information can vary from having a lot of overlap to being very distinct
- We encode everything together at the same time rather than separate encoders for each input modality, perhaps more difficult to scale

Problems on the Horizon

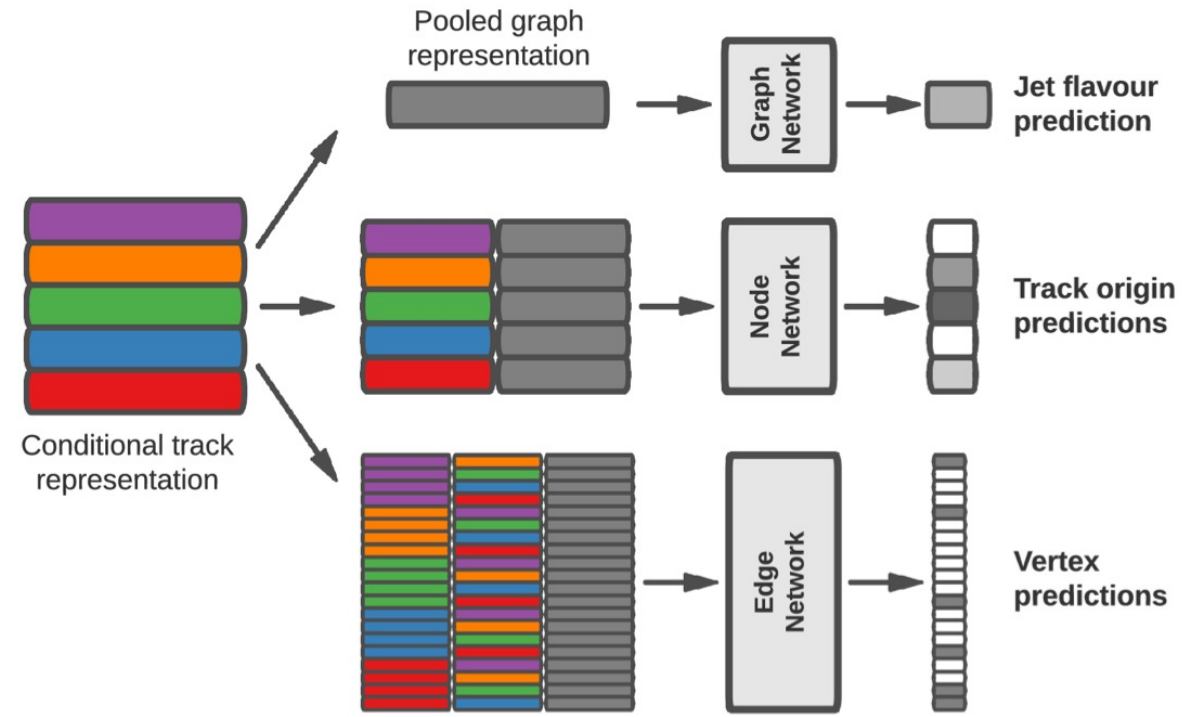

- We use simulation to train these models but no simulation is perfect
- Expanding the number of modalities and granularity can expose more places where our simulation is lacking
- Potentially resolved with foundation models – [unsupervised pre-training can be done on data, no simulation needed!](#)

Log likelihood ratio of classifier in simulation and in real data

Multiple Tasks

- End goal is to identify the flavour of jets but the **additional auxiliary tasks** are shown to **enhance performance of the main task**
- Auxiliary tasks such as identifying which tracks originate from a common origin or identifying fake tracks act as stepping stones to the main task

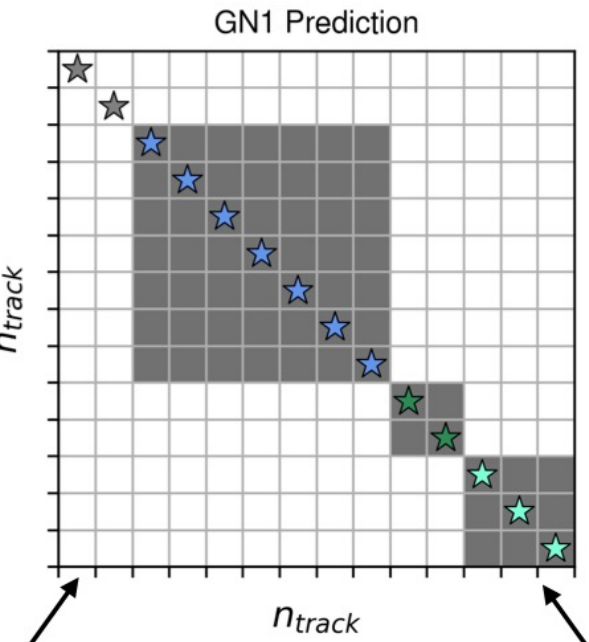

Auxiliary Tasks for Interpretability

GN1 successfully predicts jet flavour

ATLAS Simulation Preliminary
 $\sqrt{s} = 13 \text{ TeV}$
 $t\bar{t}$ jets

Truth b -jet
 $p_T = 134.1 \text{ GeV}$

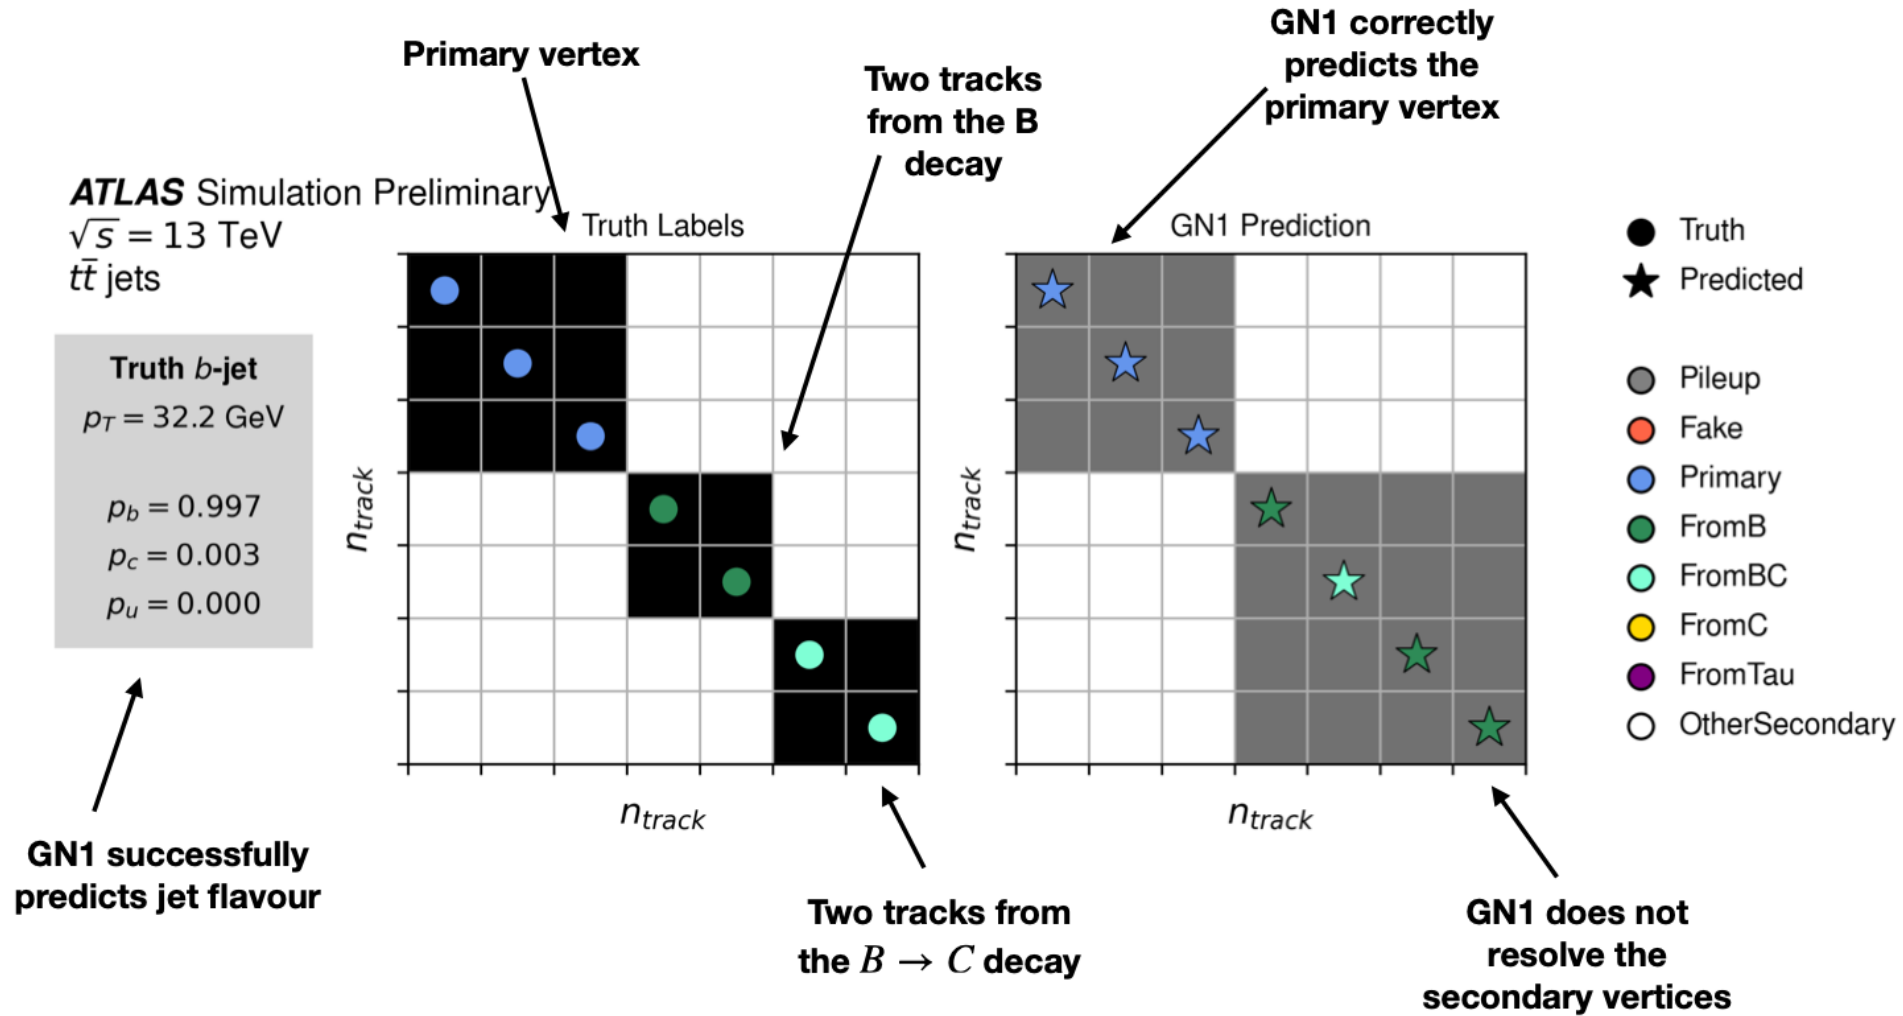

$p_b = 0.995$
 $p_c = 0.005$
 $p_u = 0.000$

GN1 vertex and origin prediction is perfect

- Truth
- ★ Predicted
- Pileup
- Fake
- Primary
- FromB
- FromBC
- FromC
- FromTau
- OtherSecondary

Auxiliary Tasks for Interpretability

- More studies on interpretability in flavour tagging by Scott [in the next talk](#) using a different technique

Object Detection for Vertex Reconstruction

- The additional auxiliary tasks are beneficial to the main task performance – but can we extract even more information?
- e.g. trying to reconstruct the full decay chain of particles
- **Idea:** use object detection techniques to identify vertices and the properties of the particles they belong to

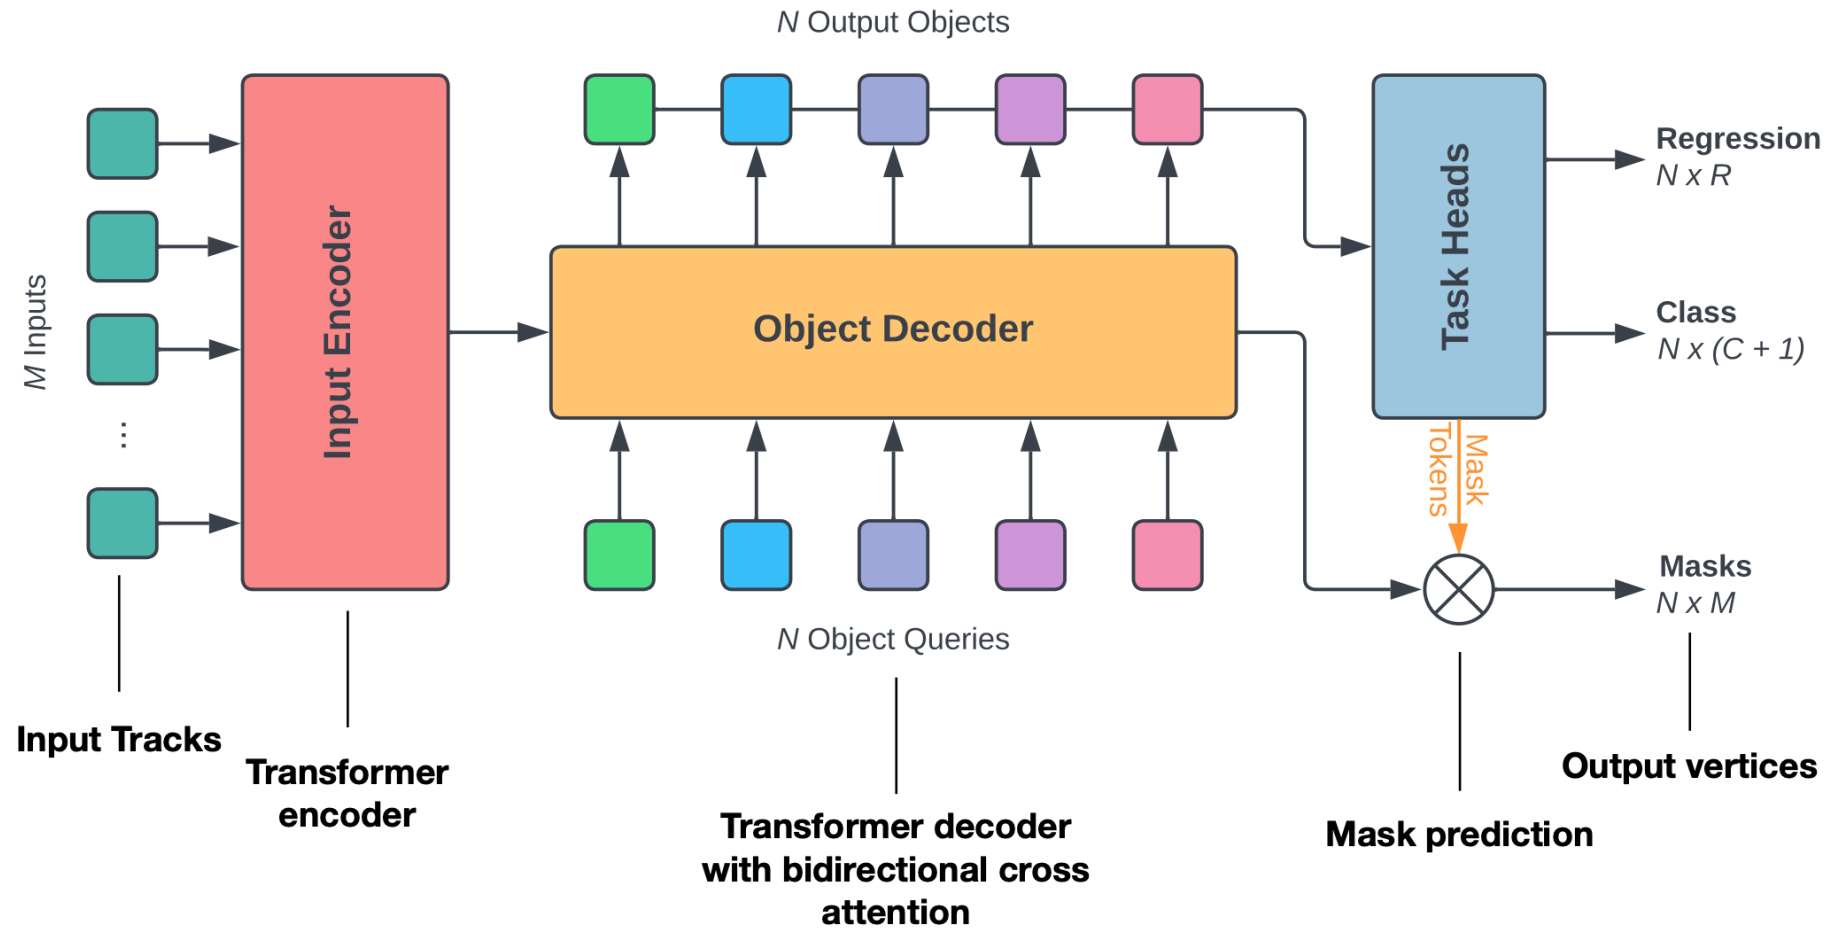

Segment Anything

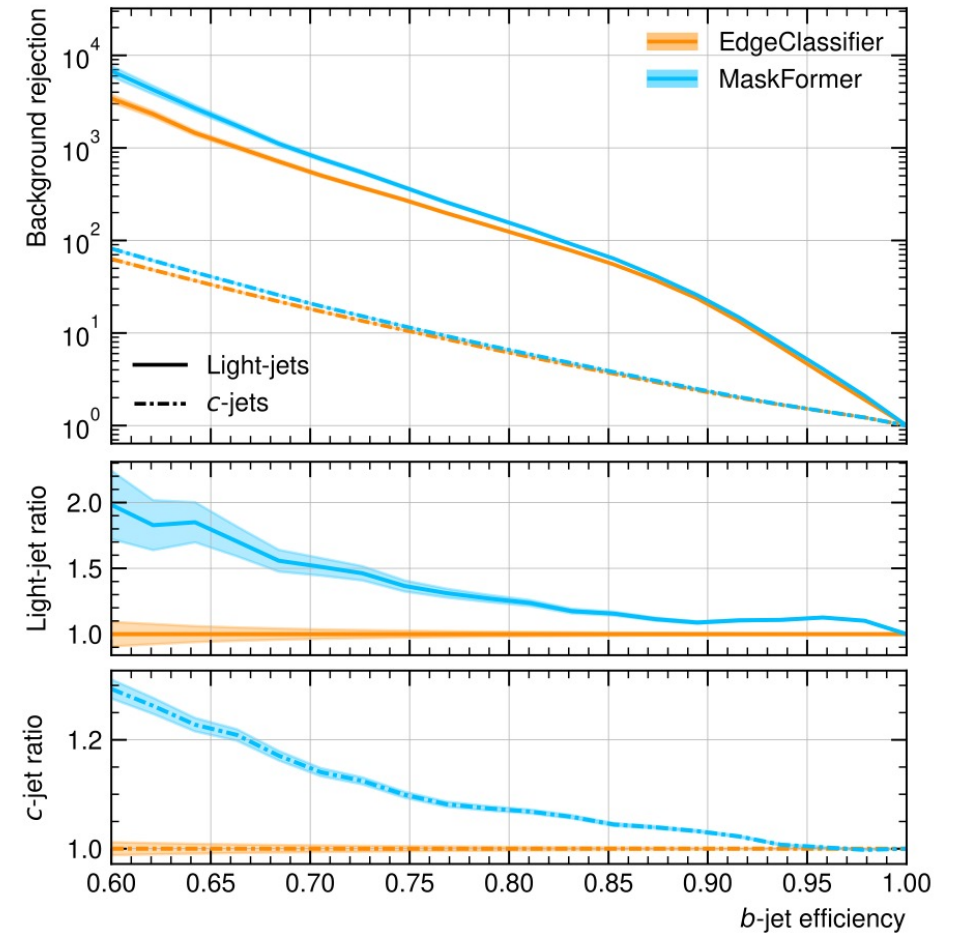

- [Segment Anything](#) is the current state of the art for identifying objects in images by learning binary masks over pixels
- Translated to flavour tagging we want to reconstruct vertices in jets by learning binary masks over tracks (and whatever else)

MaskFormer

MaskFormer Results

- The MaskFormer style vertexing further improves in the main flavour tagging task performance over the simpler edge classifier task
- Multi-task learning is a good way of including our physics knowledge of what things are related as inductive biases within the model
- But will this still hold as we scale larger or does the bitter lesson continue to be true?

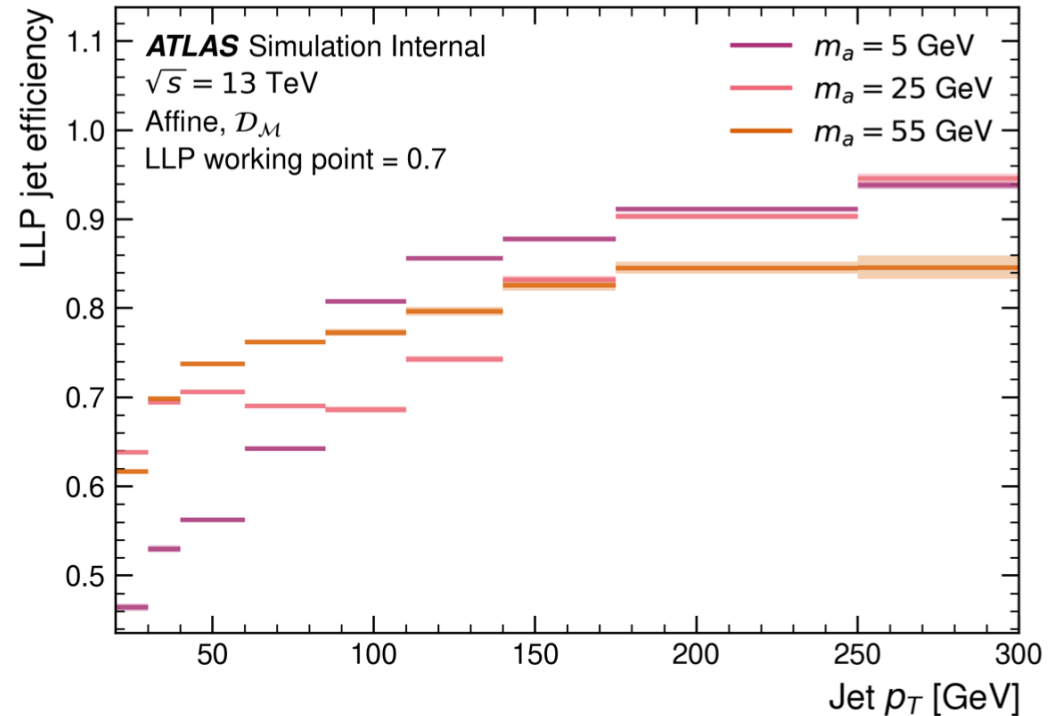

[arXiv:2312.12272](https://arxiv.org/abs/2312.12272)

Beyond Flavour Tagging

[ATL-PHYS-PUB-2024-015](#)

[E. Haines Thesis](#)

- The tools and pipelines used are fairly agnostic to the task at hand – it has been adapted to a range of other ATLAS physics results including Jet regression and Long Lived Particle searches
- It's easier to consider combining lots of different things in a foundation model if we're all speaking the same language to begin with

Conclusion

- Particle physics detectors give us a wide range of types of data ranging from low-level information straight from sub-detectors to high-level information reconstructed by different algorithms
- Flavour tagging is an example use case that uses this information and has seen significant improvements in recent years as we try to exploit more and more of this information
- Multiple tasks help generalisation and can improve performance on any individual task – another reason why foundation models are an interesting goal
