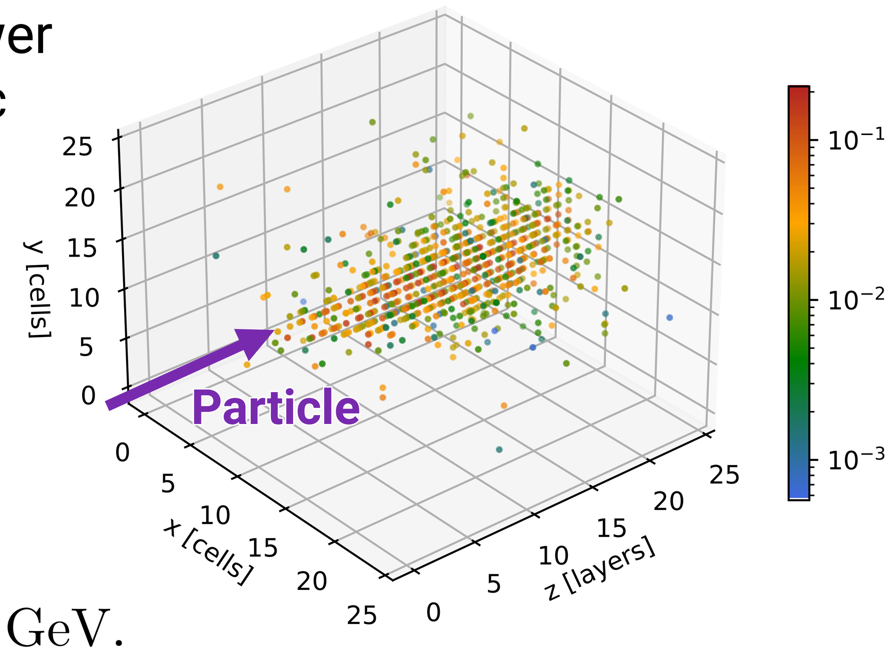
Motivation & Challenges

- **Use case**: simulation of shower images from electromagnetic calorimeters in particle physics with Quantum Machine Learning.
- **Dataset**: training and test datasets both consisting of condensed 1D images recorded by particles within the energy range of $[225, 275]$ GeV.



Why Quantum?

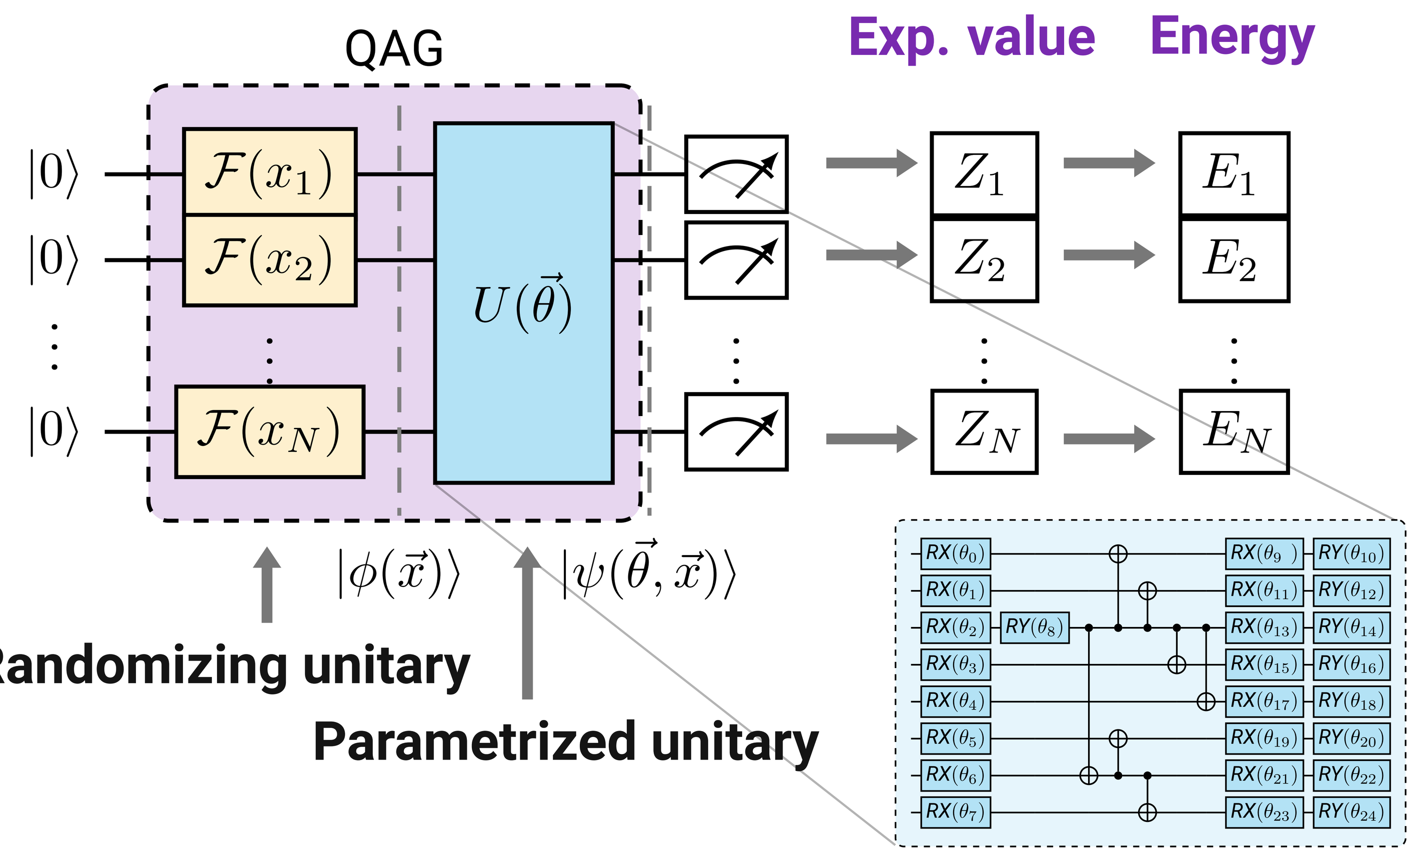
- Generation is **inherently probabilistic**, which can be represented by wavefunctions.
- Hilbert space is able to represent complexity easier.

Challenges in QC

- Presence of noise in NISQ devices.
- Gradient-free optimizations.
- Size of the I/O capabilities.
- Limited hardware availability.

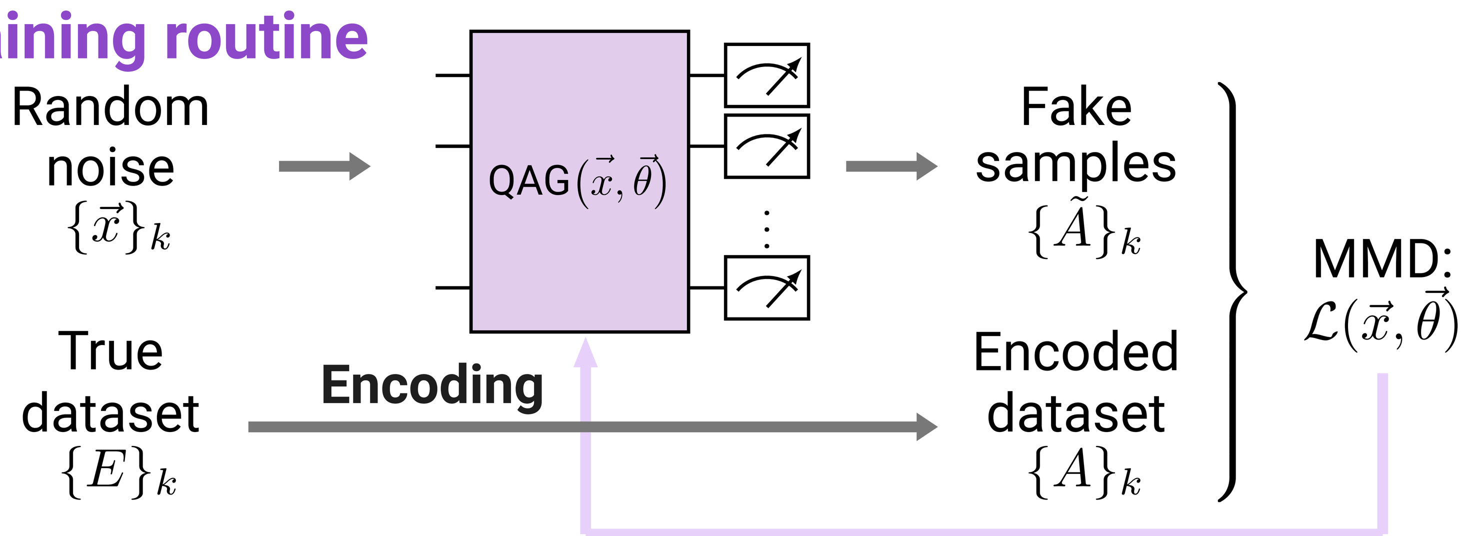
Quantum Angle Generator

- **Model**: quantum generative model that employs angle encoding.
  - **Encoding**: classical images into a quantum state, by encoding pixel energies into rotational angles of qubits.
  - **Decoding**: translate repeated measurements of quantum states into energies.

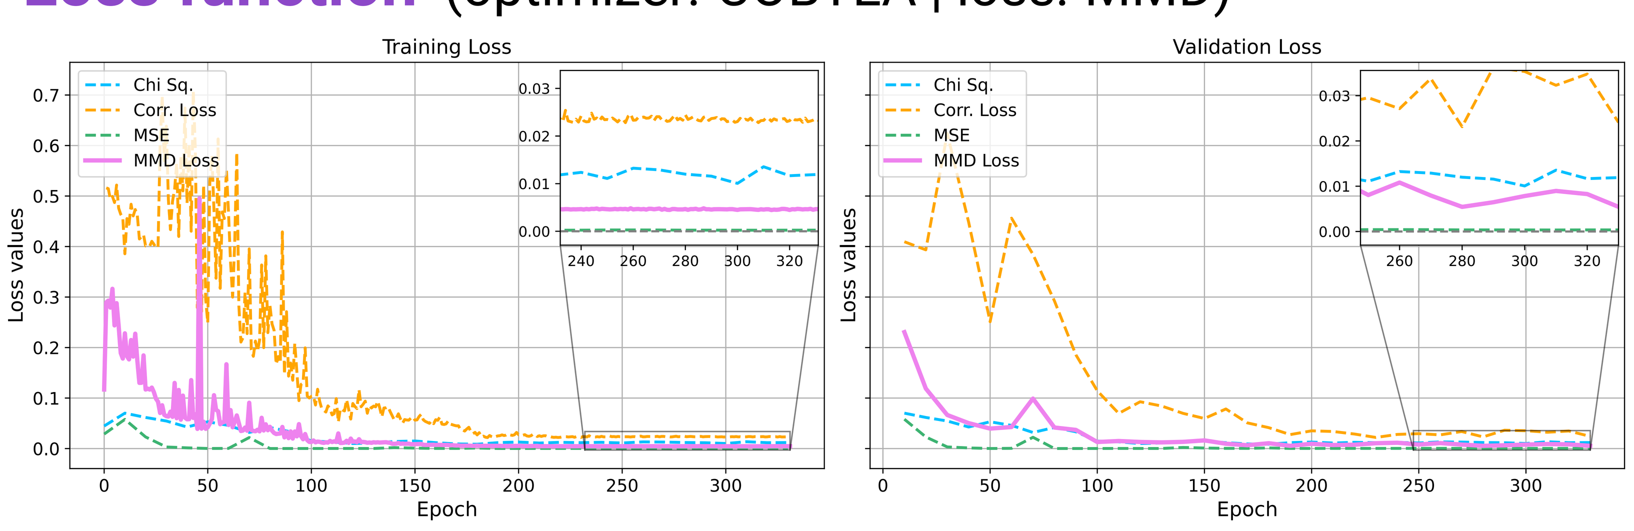


Training evaluation

Training routine



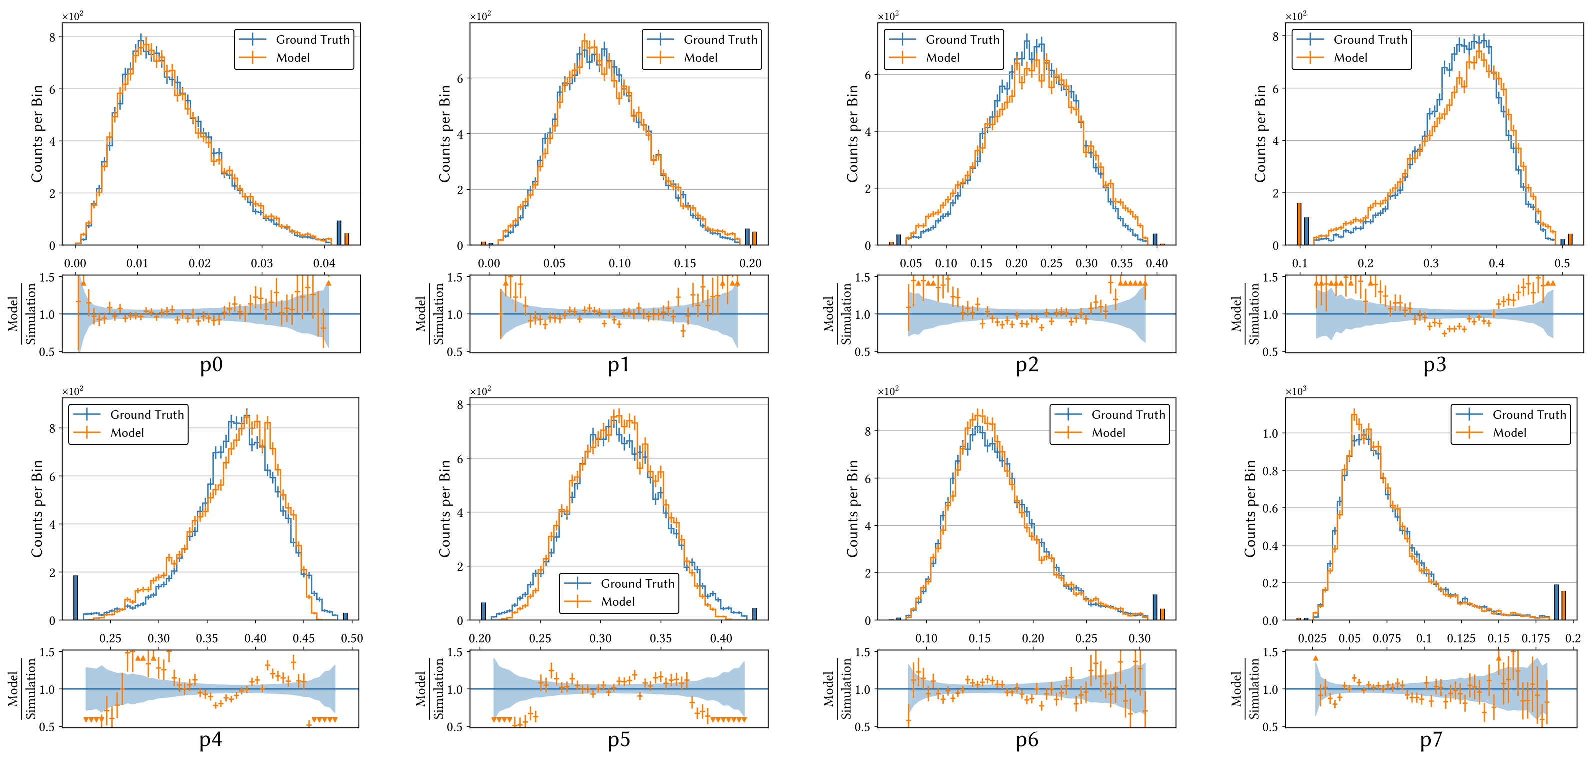
Loss function (optimizer: COBYLA | loss: MMD)



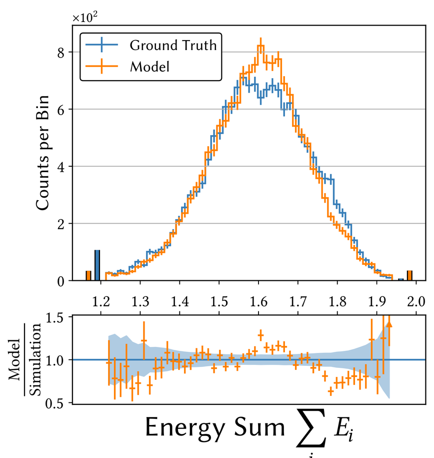
★ MMD loss alone is able to effectively learn **correlations between pixels**

Inference evaluation

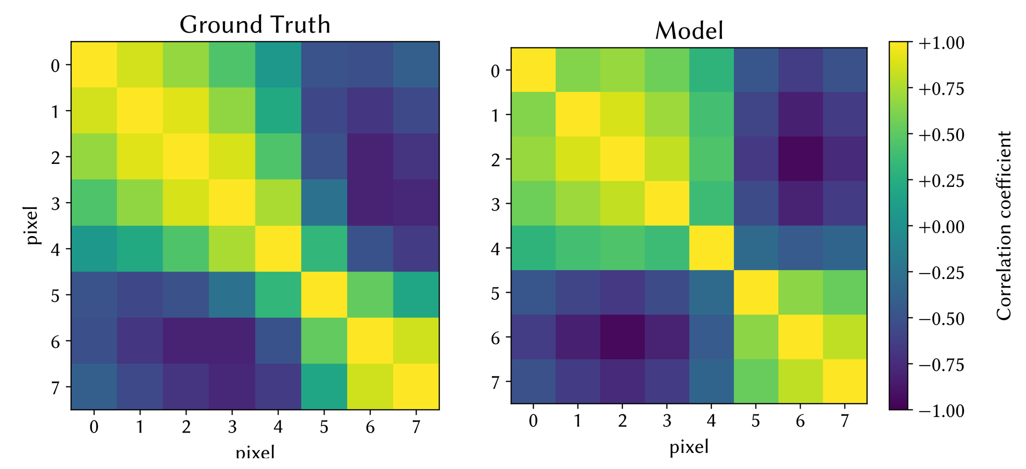
Pixel-wise distributions



Energy sum



Pixel correlations

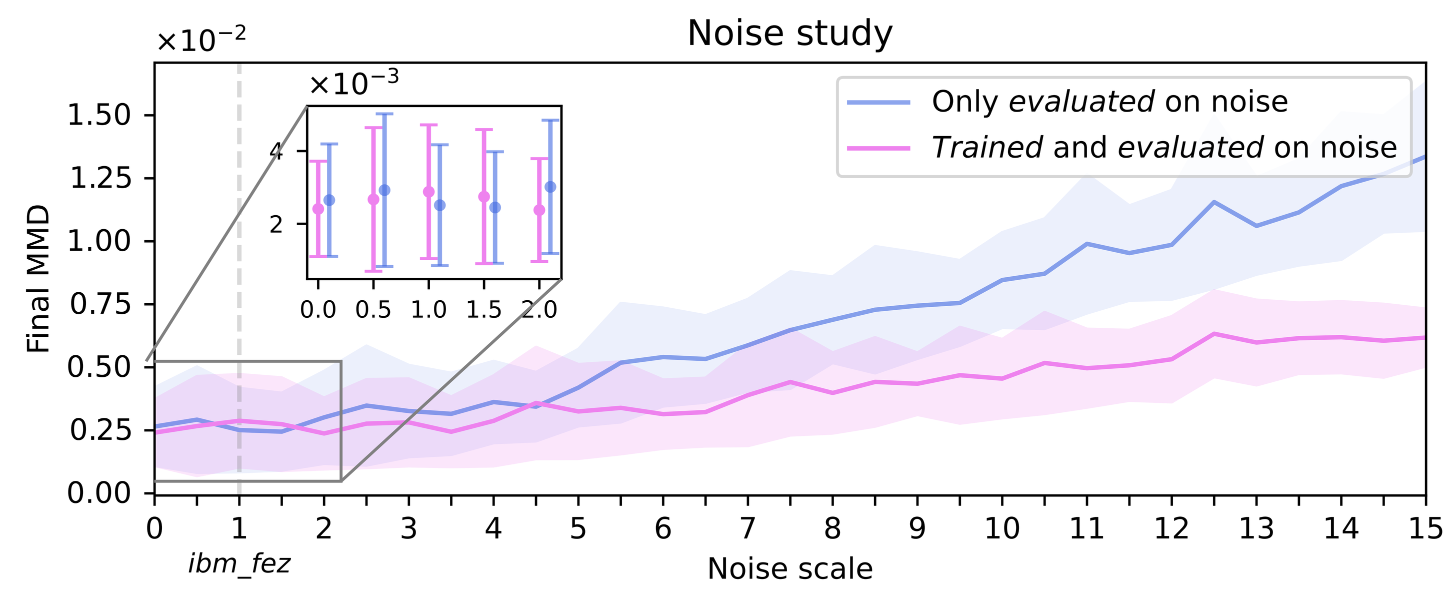


★ The model successfully captures pixel correlations and accurately reproduces the expected energy distributions

Noise study

Two types of models trained at different noise scales:

- trained on noiseless simulator, evaluated on noisy instance
- trained and evaluated on noisy instance



★ For high noise levels, the model is capable of **adapting to the underlying noise**.
Current noise levels on real QPUs do not impact performance.

Implementation on real hardware

Testing the architectures on real quantum processors under different quantum hardware **noise types and levels**.

IBM	IQM	eleQtron
Superconducting	Superconducting	Ion-trap
