Precise measurement of the W boson mass with the CMS detector at the CERN LHC

Kenneth Long for the CMS Collaboration

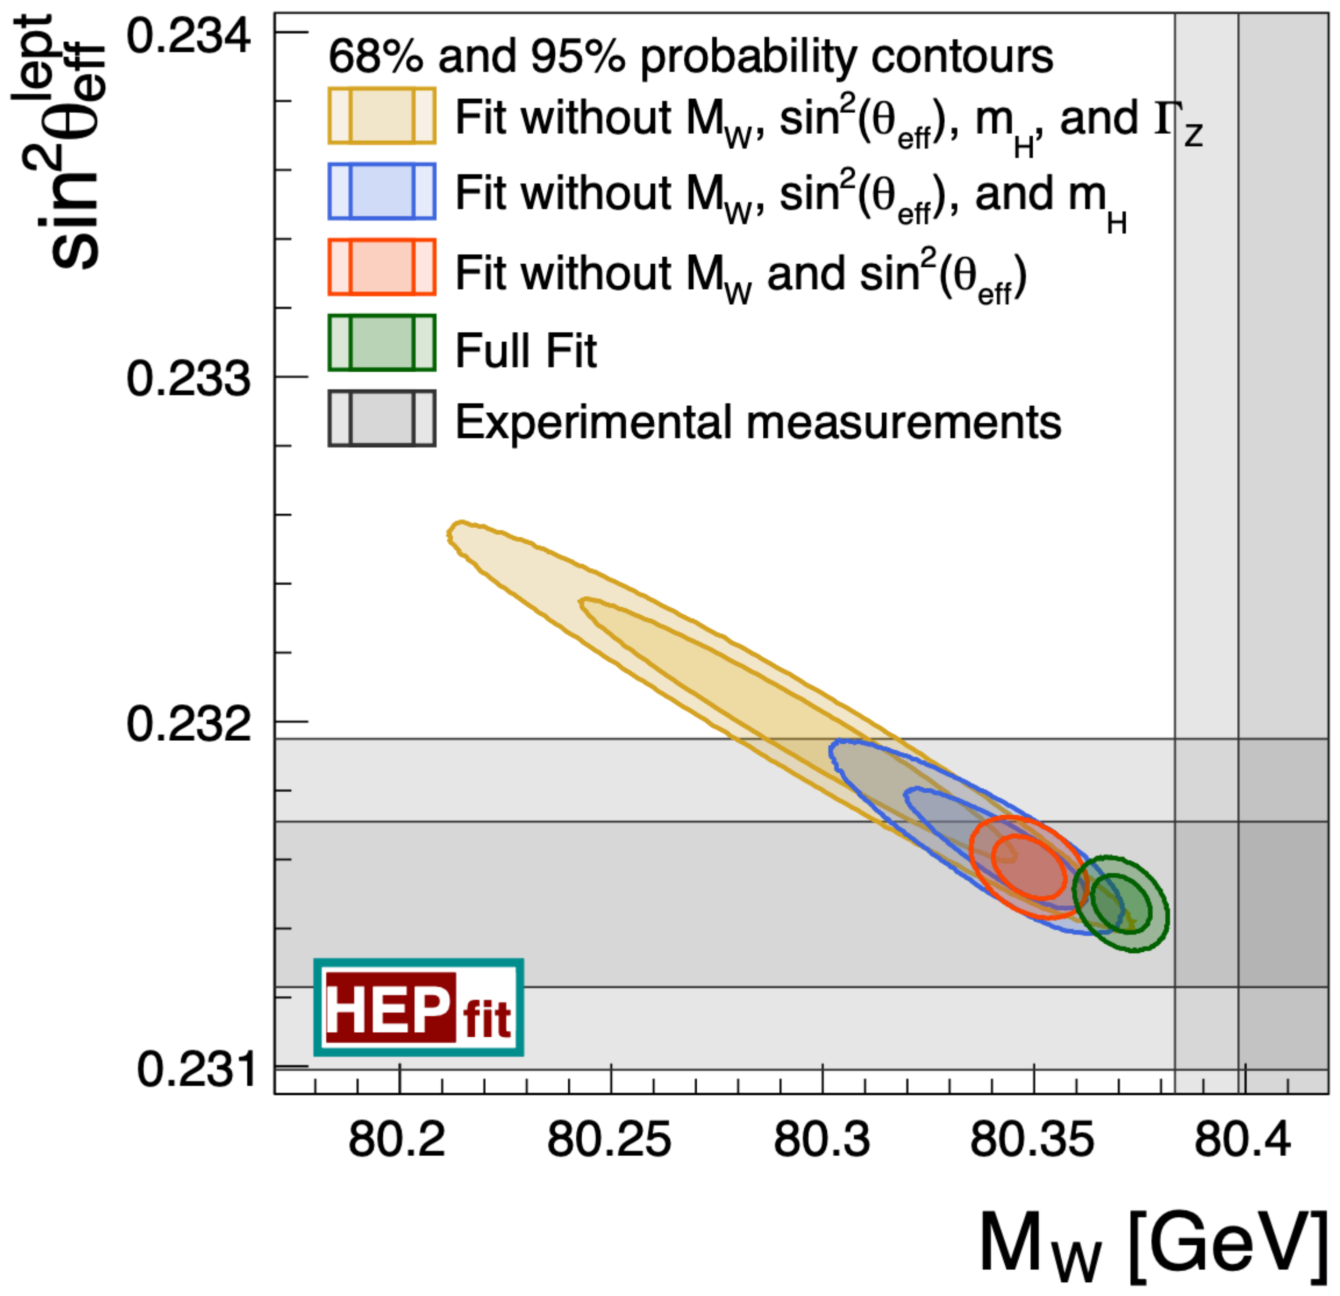
Introduction and motivation

- Masses, couplings are experimental inputs to the SM
  - But relationships between parameters are **exactly predicted**
  - Direct measurements over-constrain the SM

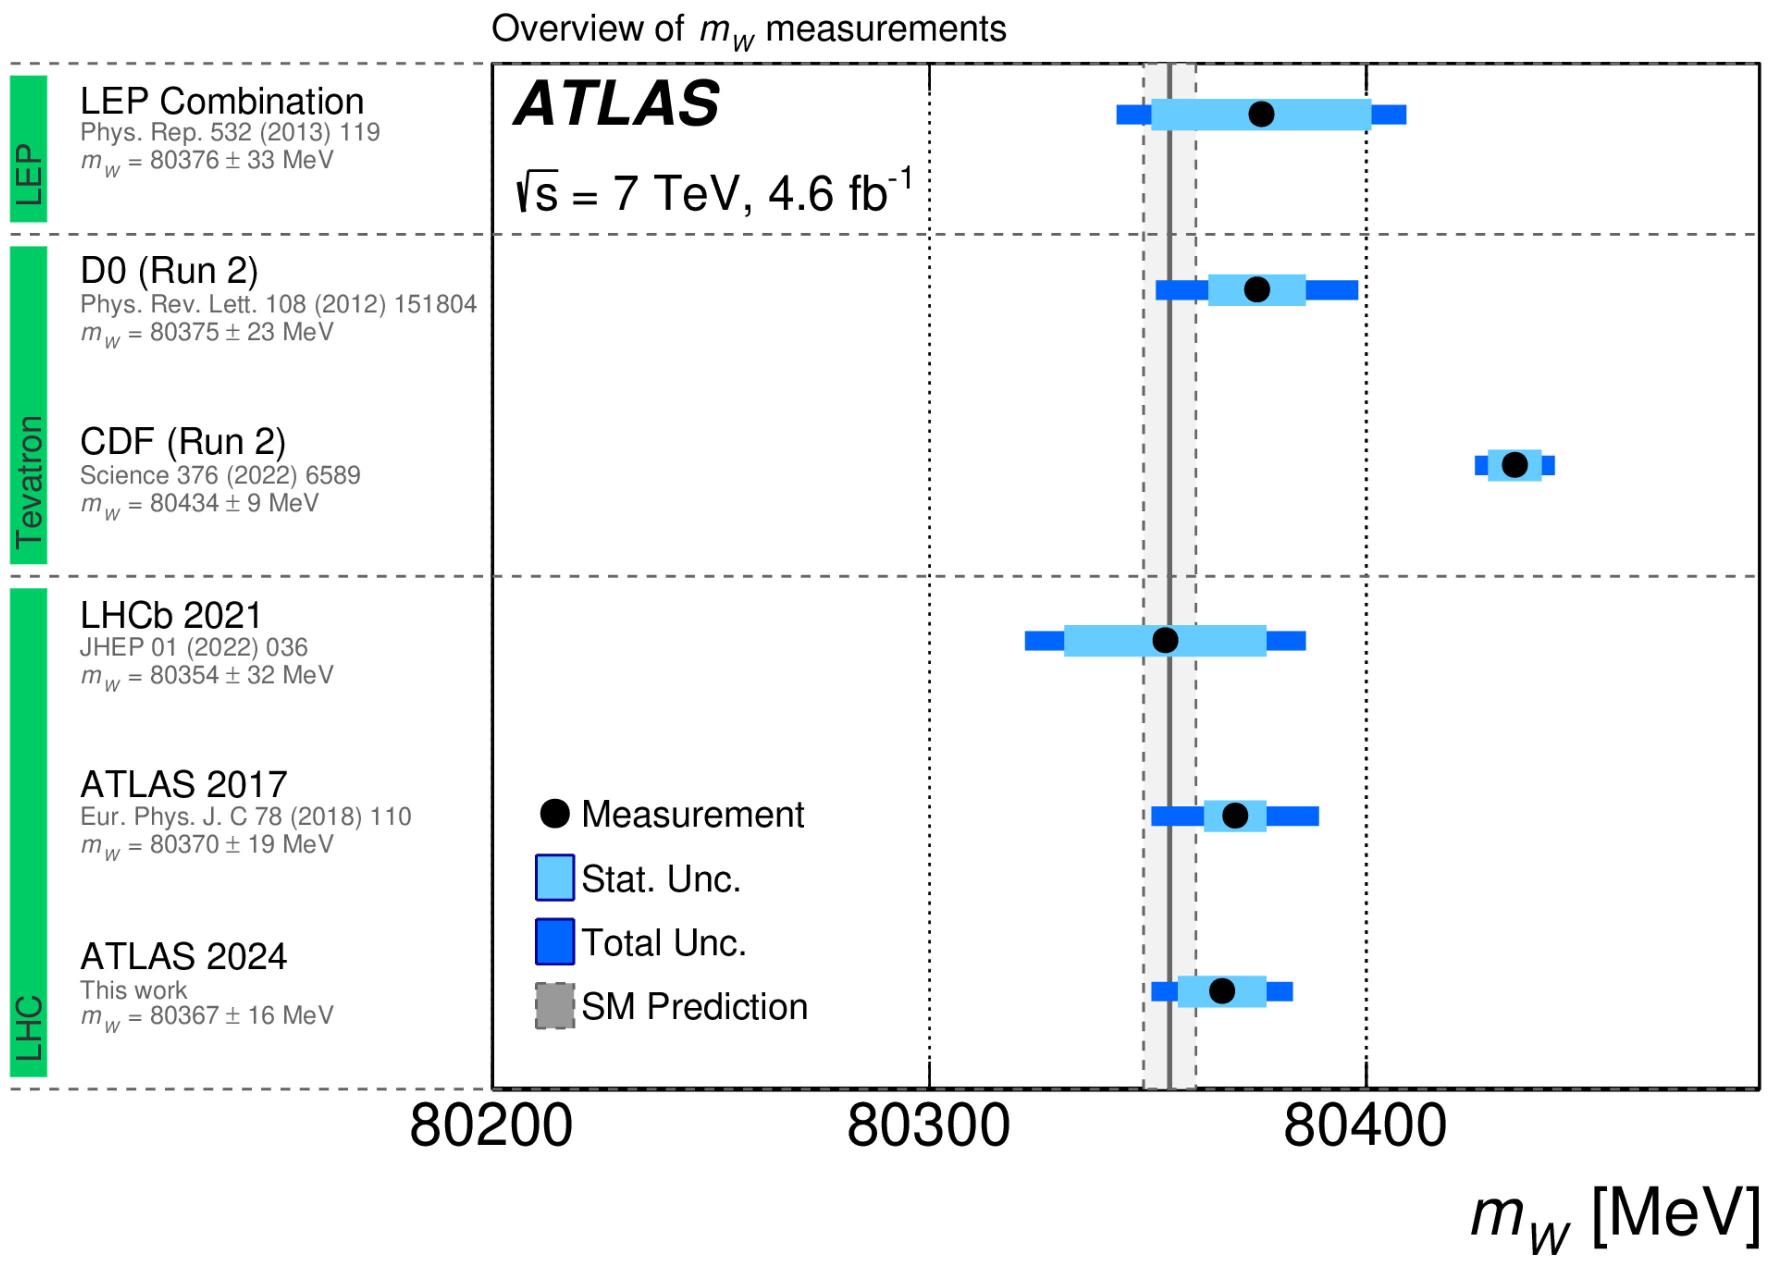
$$m_W^2\left(1-\frac{m_W^2}{m_Z^2}\right)=\frac{\pi\alpha}{\sqrt{2}G_\mu}(1+\Delta r)$$

Very well measured

Higher-order corrections
Depend on m_t, m_H, … m_{BSM}?



- Most precise measurement of W boson mass from CDF, m_W = 80,433.5 ± 9.4 MeV, in strong tension with expectation
  - And with other experiments… **new result needed!**

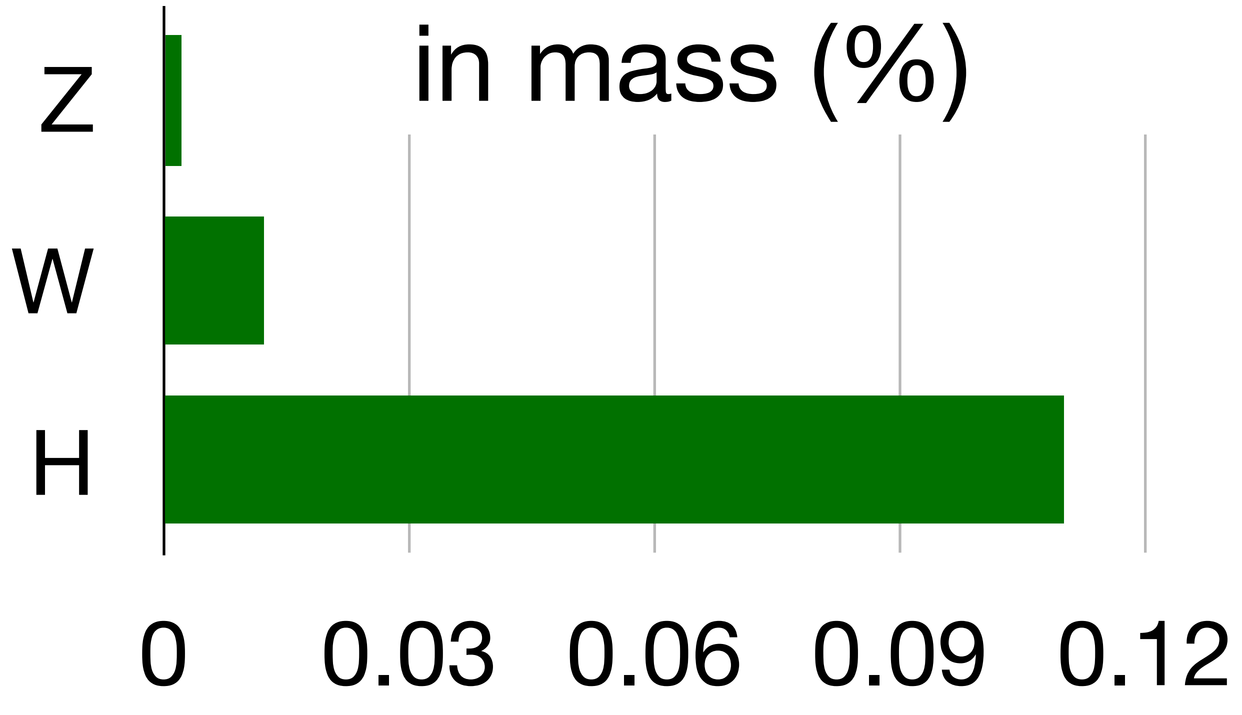


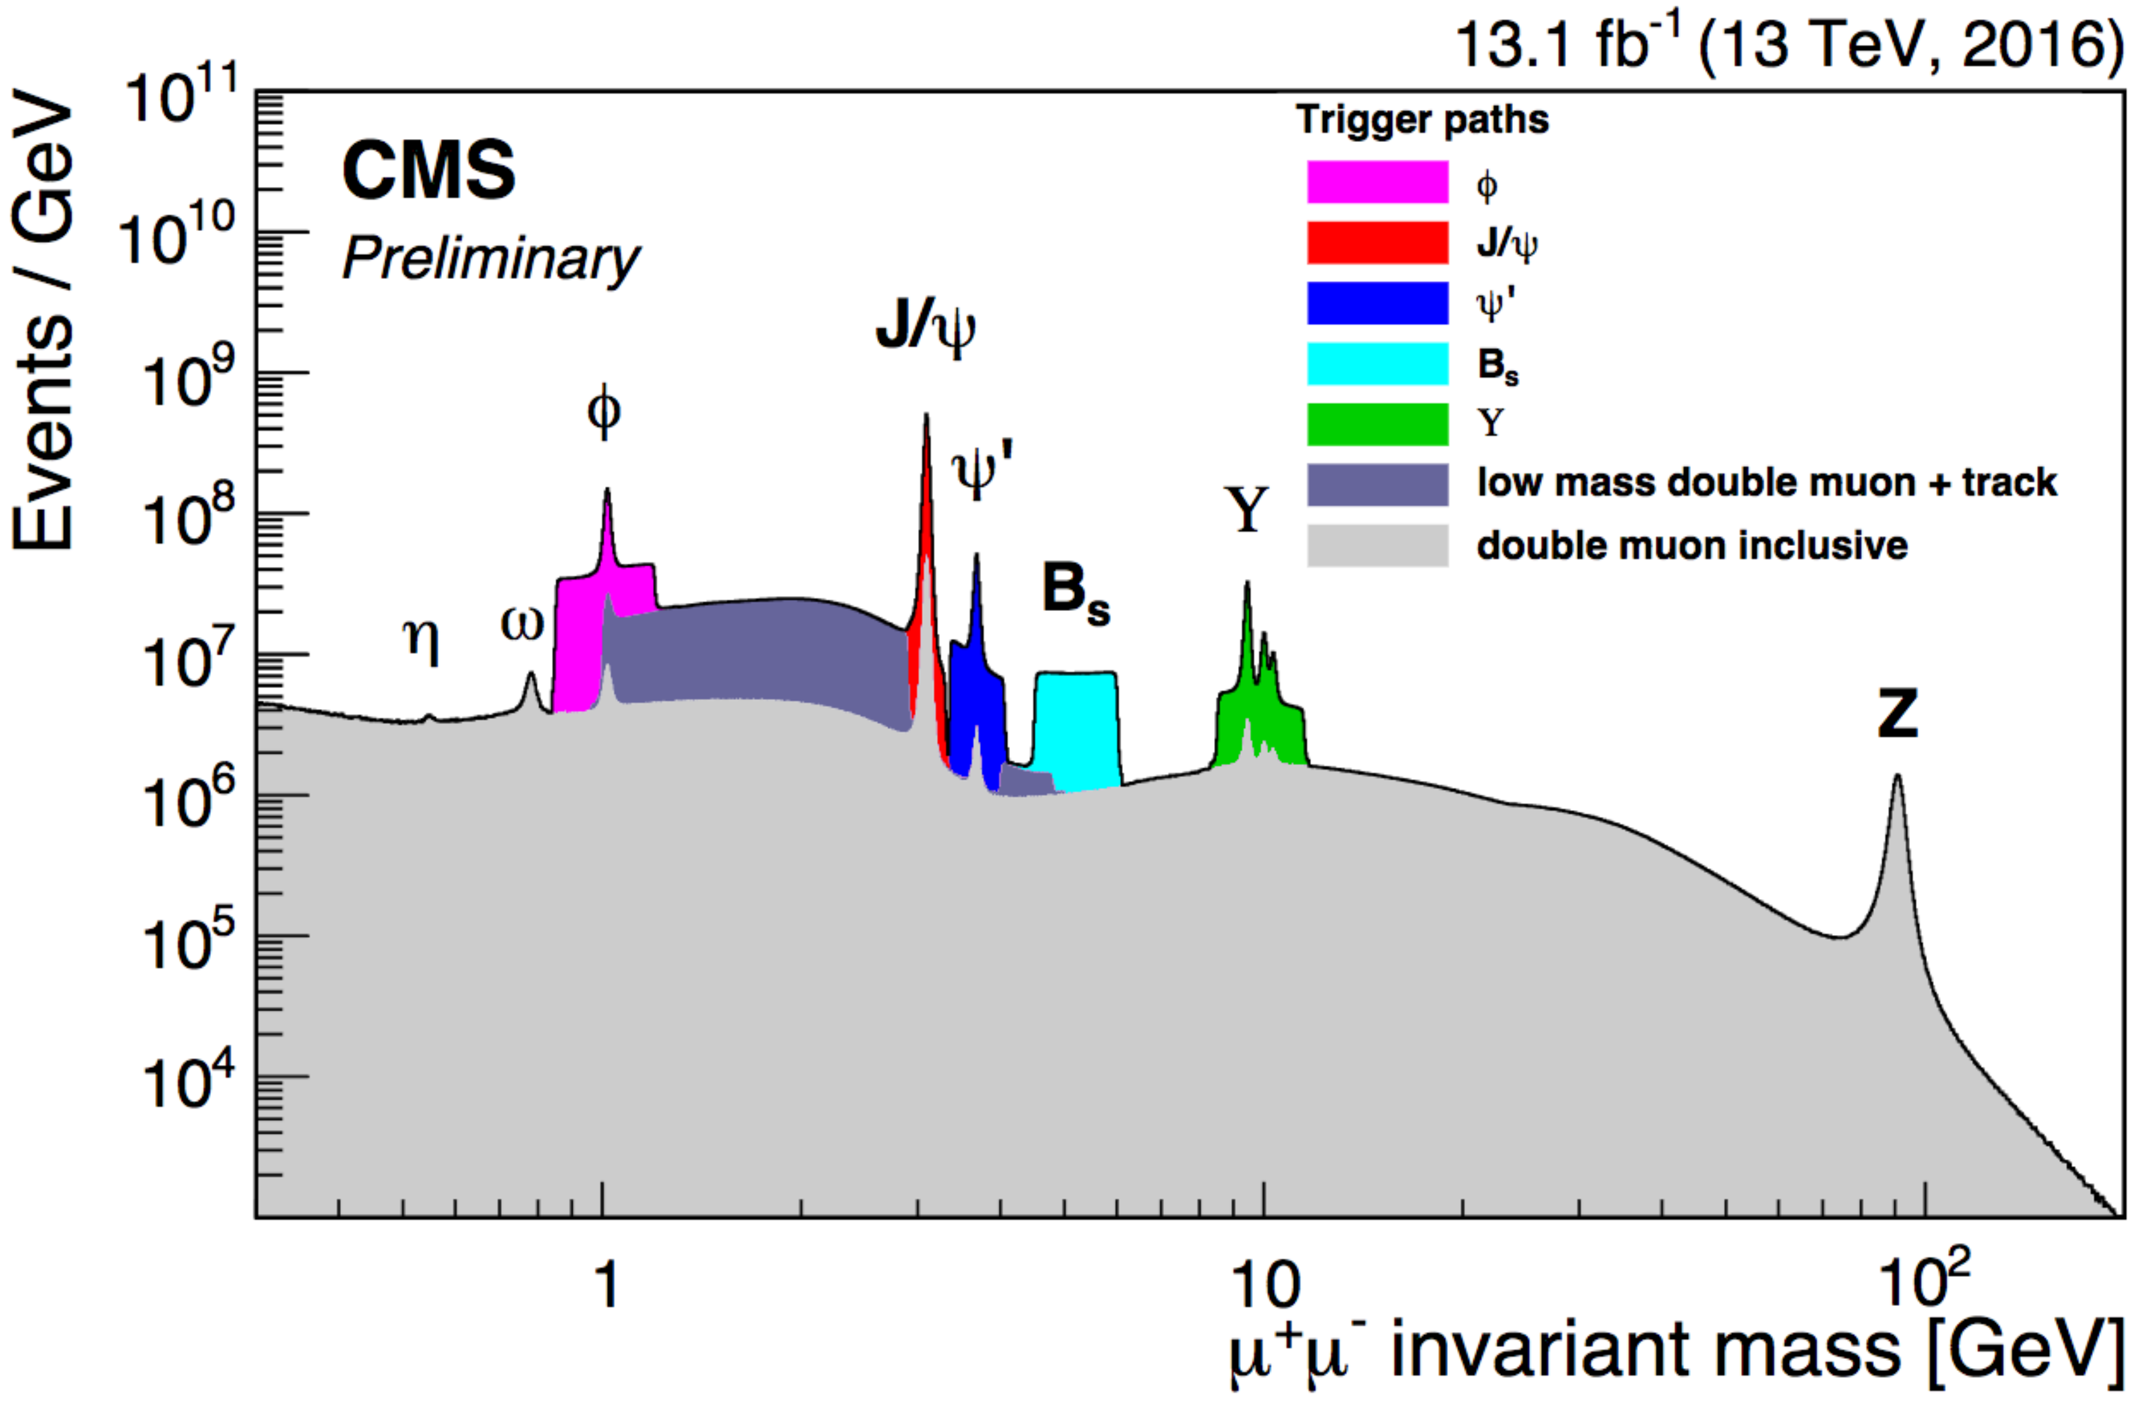
Mass measurements at colliders

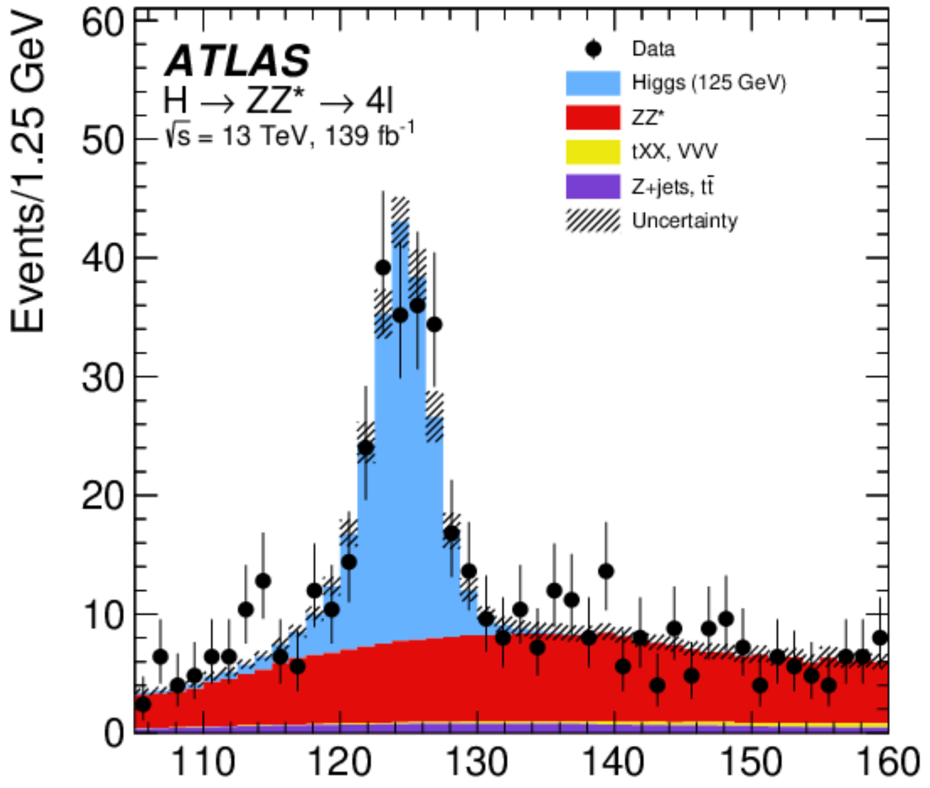
- Measure short-lived resonances via their decay productions
  - Measure momentum in detector, mass from four-momentum conservation
- Look for resonant production vs. beam energy scan
  - Not possible at hadron colliders

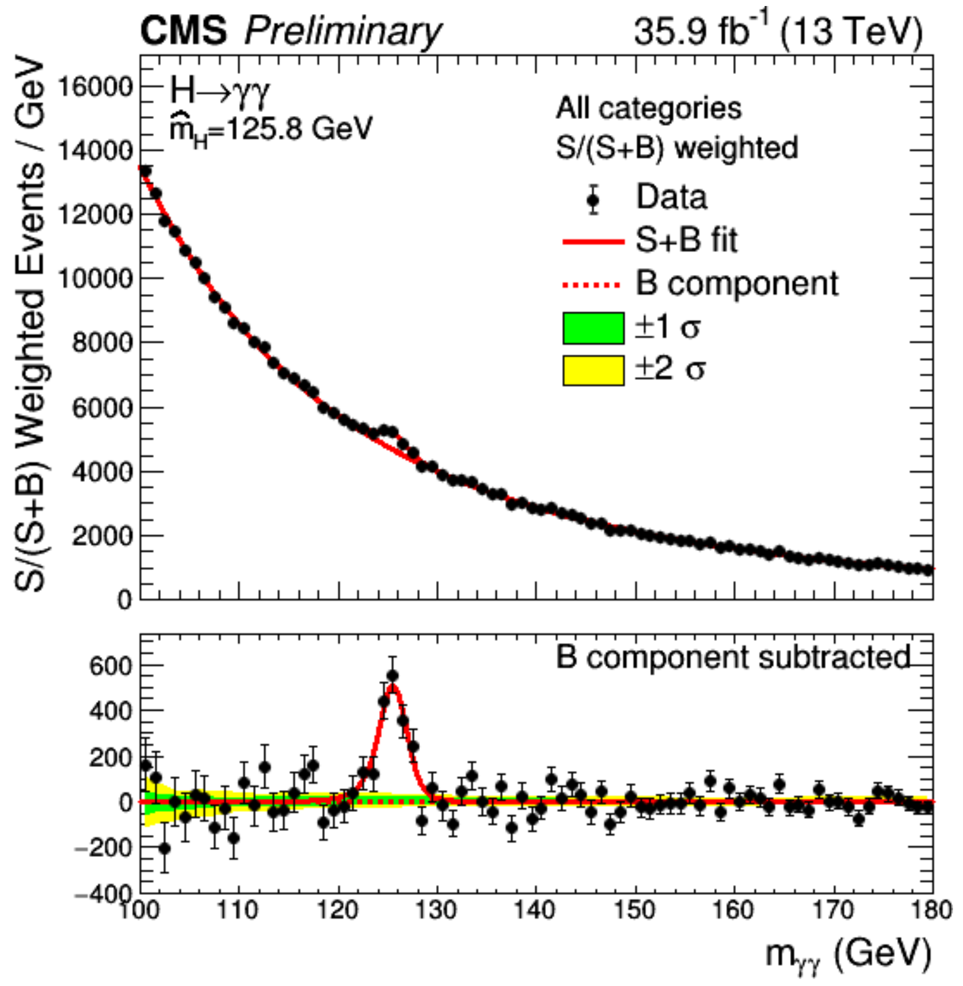
➡ Measurement of m_W ~7x less precision than m_Z
  - Very precise energy scan measurements at LEP

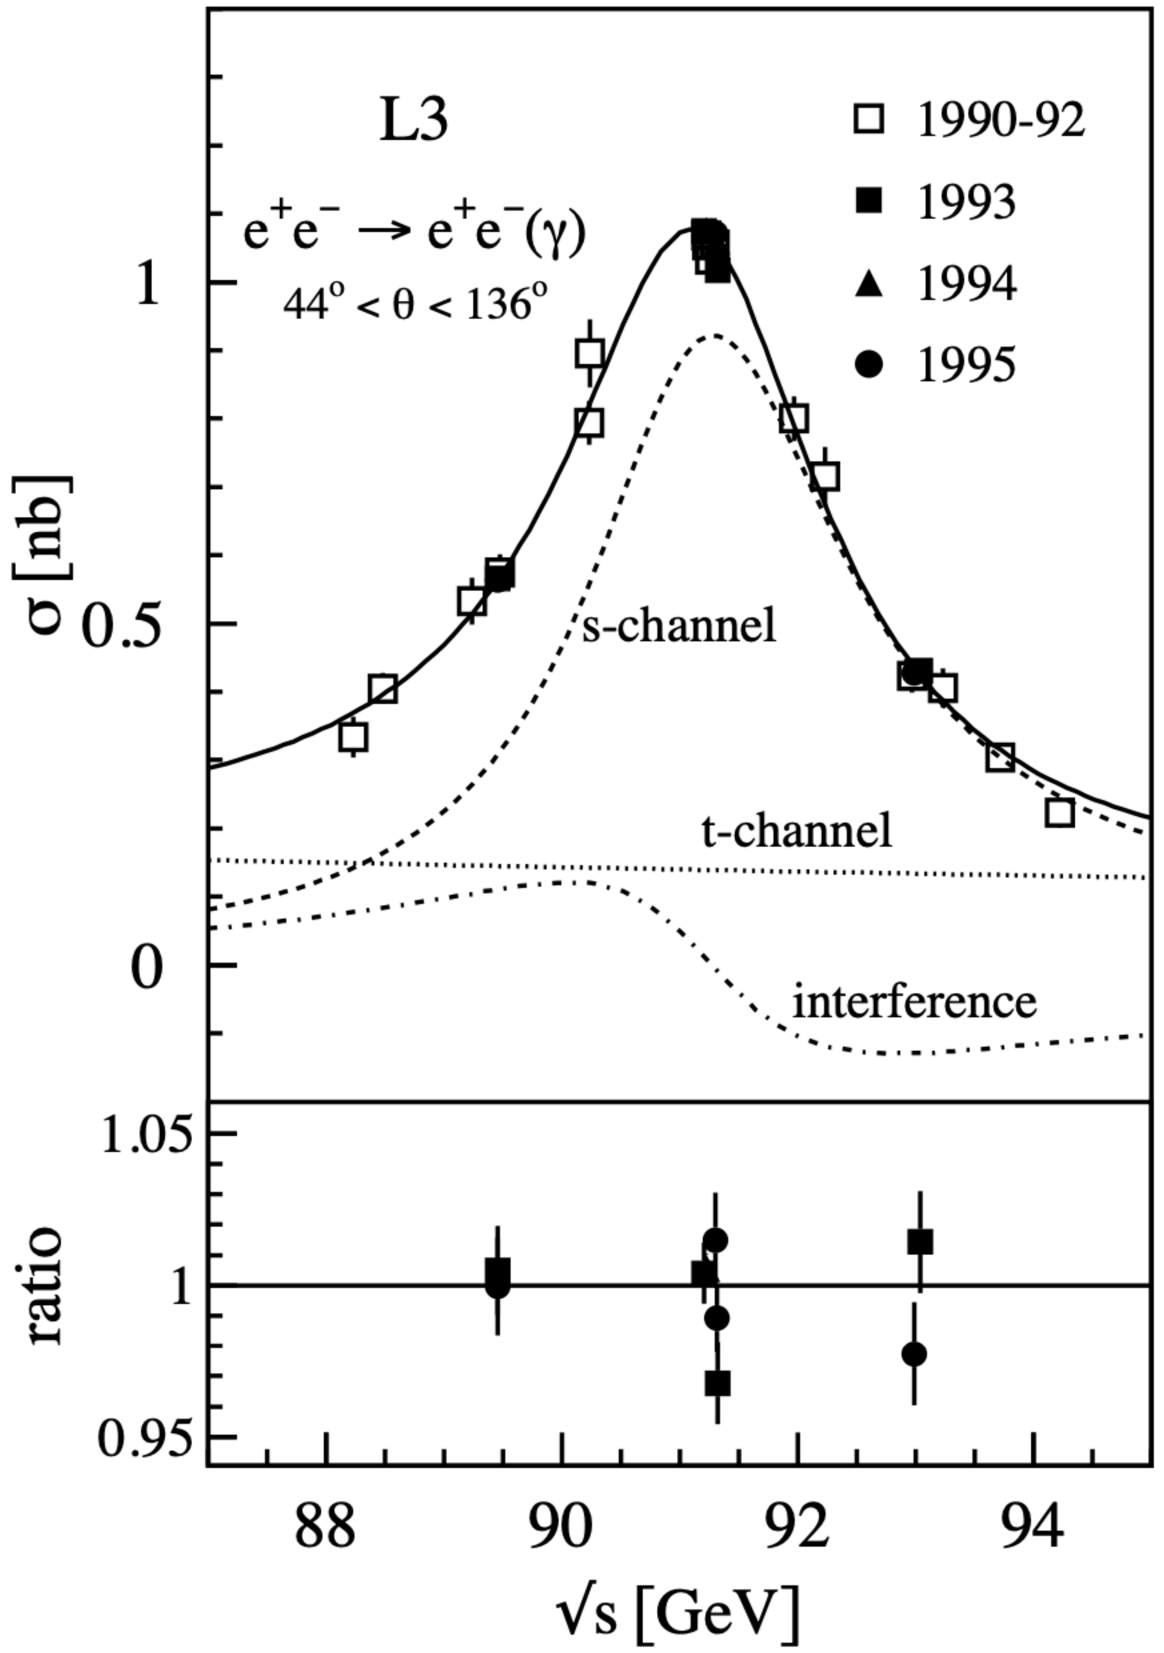
Relative precision in mass (%)







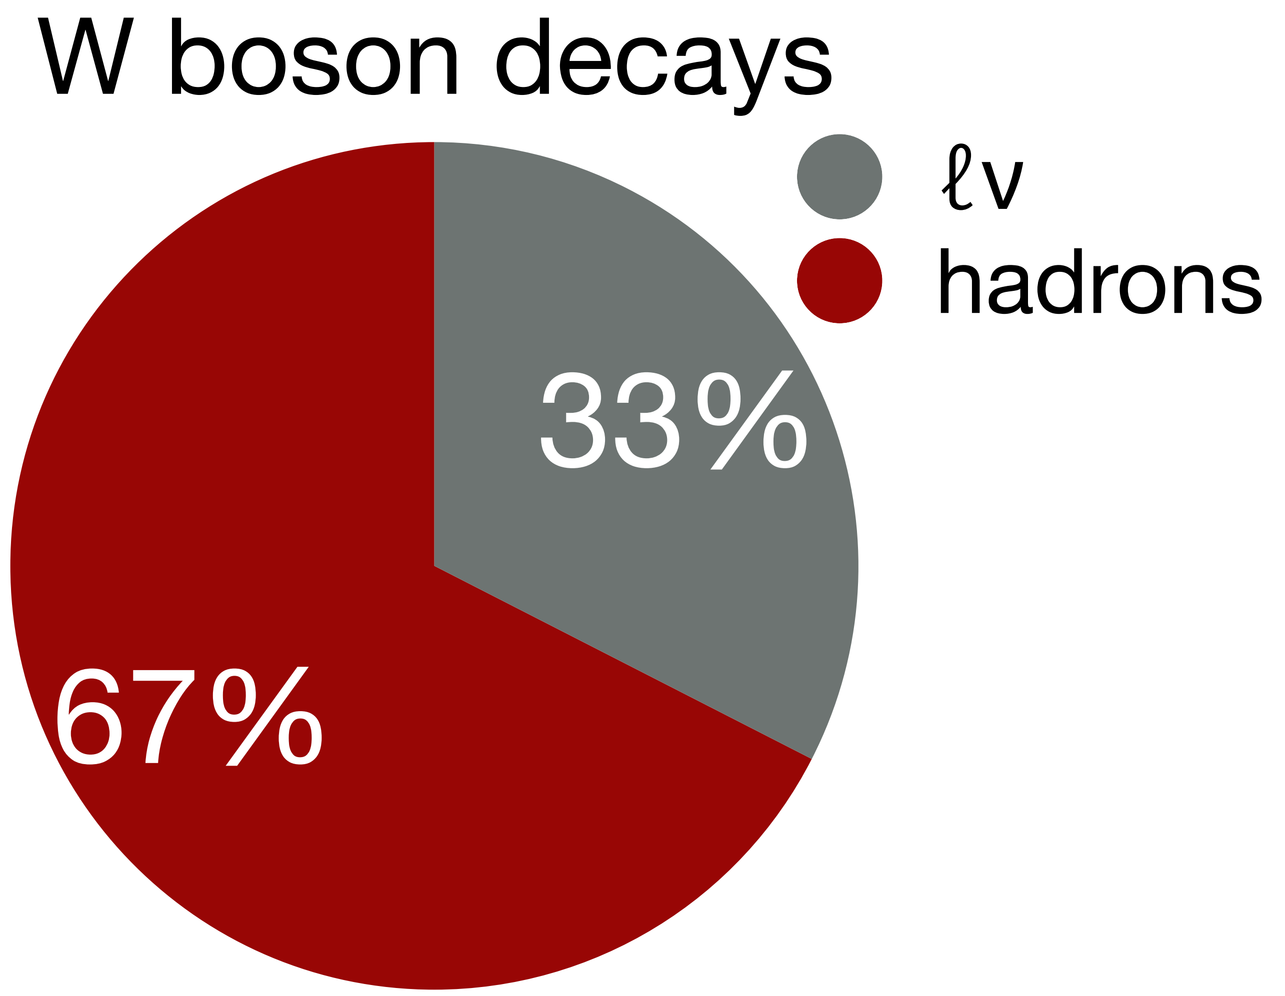


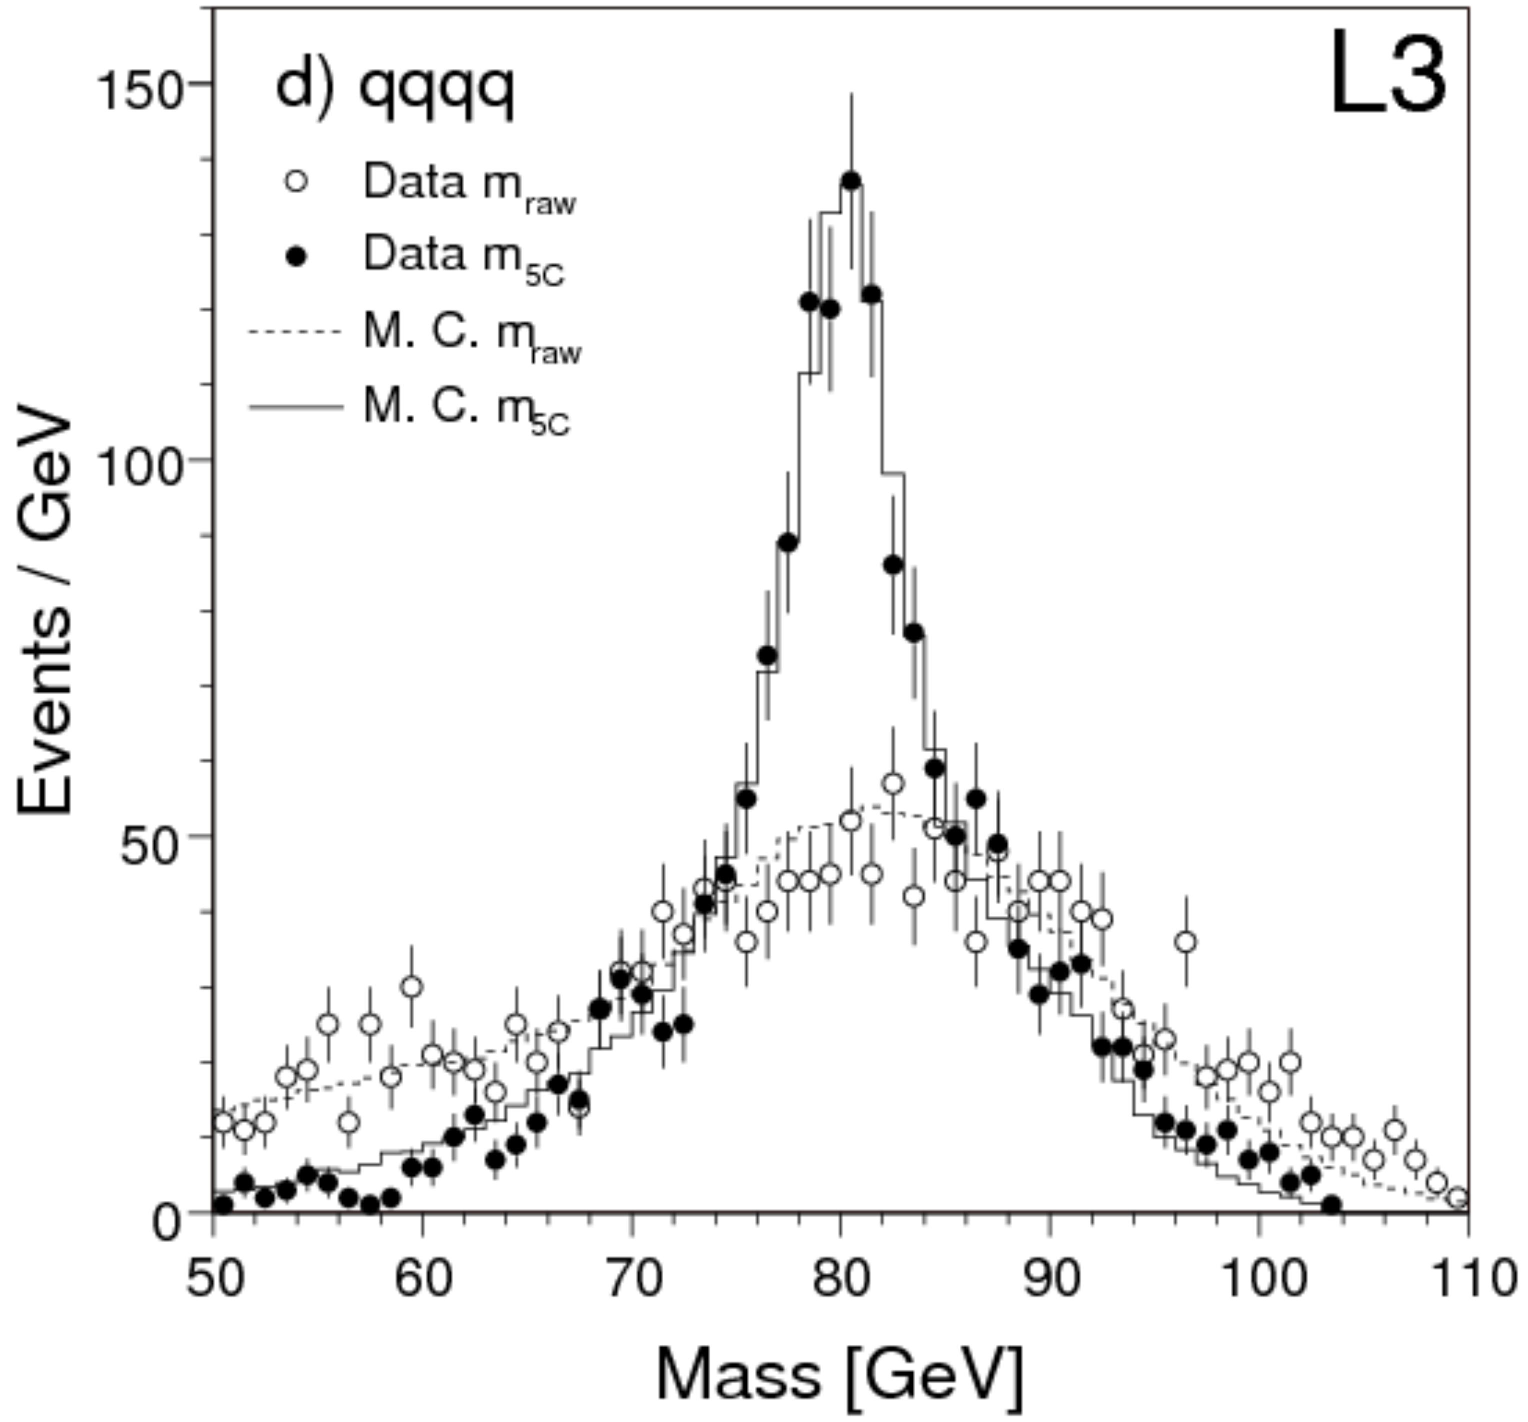


Directly reconstructing the W boson

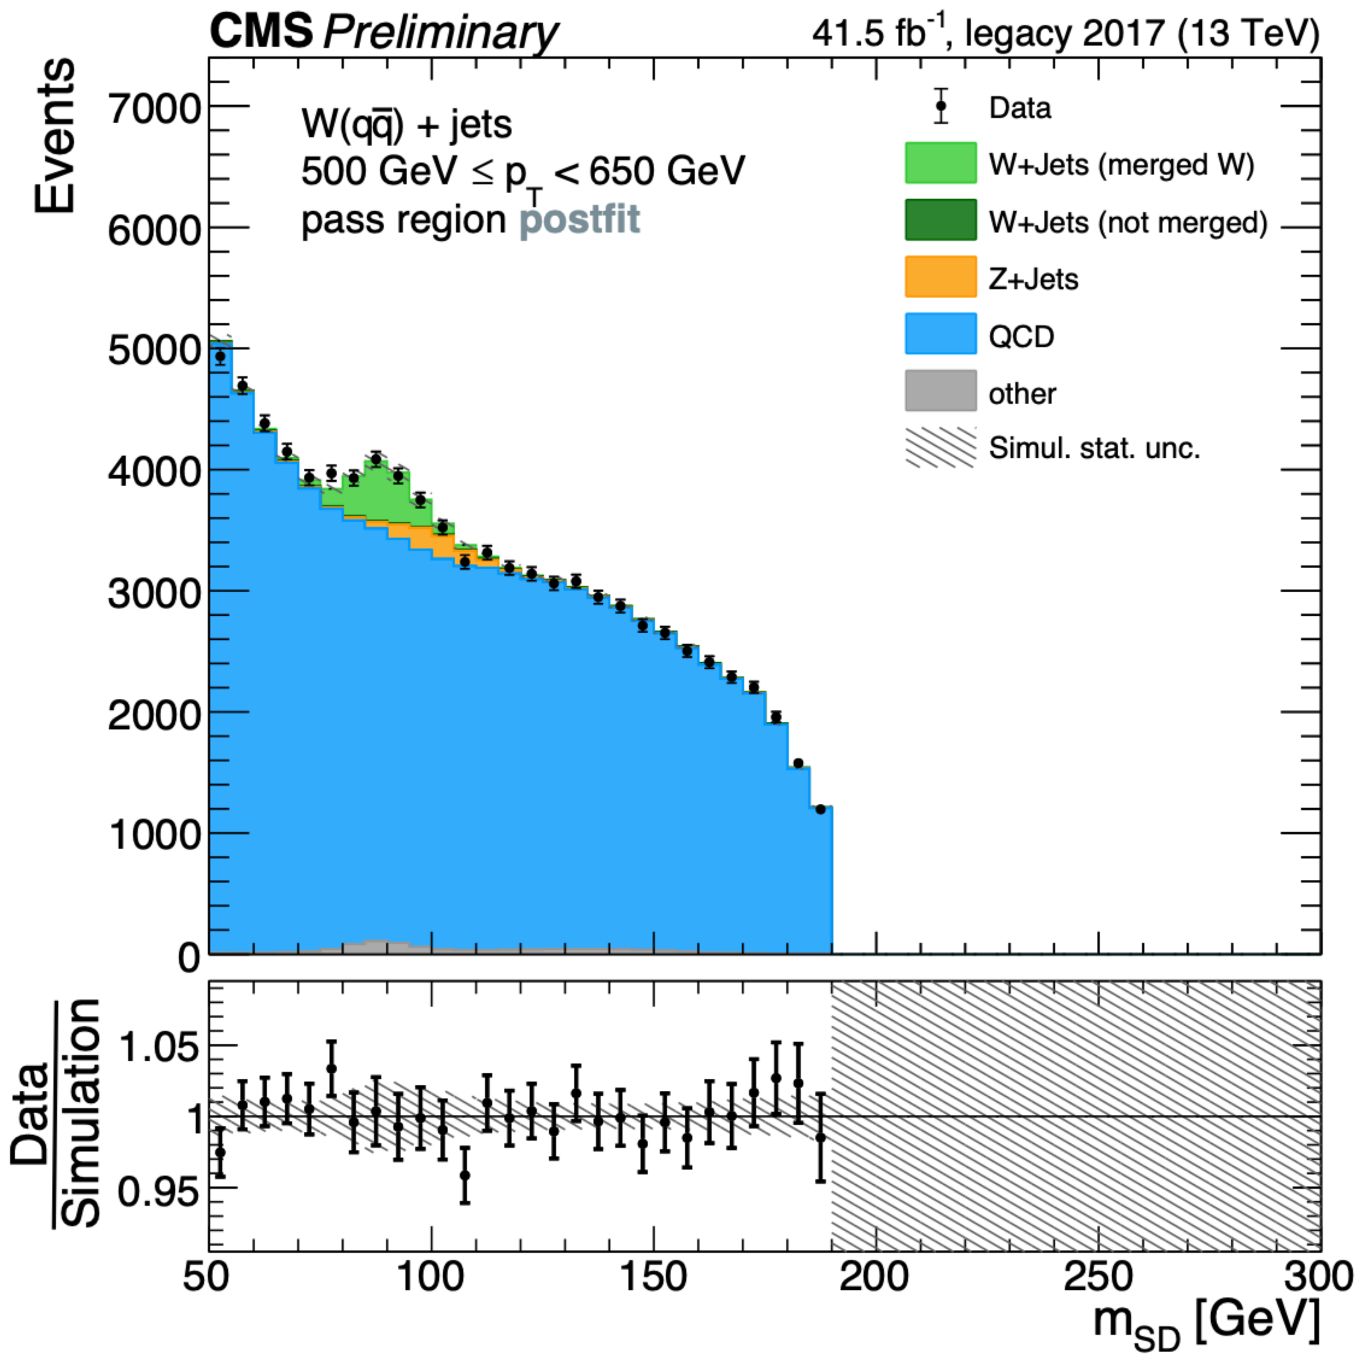
- Direct reconstruction of W possible with hadronic decays
  - Precise measurement at LEP using ee→WW→qqqq (or qqℓν) events
  - When the full decay is measured, little dependence on production details
- At hadron colliders
  - Exact initial conditions are not known (Parton distribution functions)
  - Background/calibration of jet momentum significantly more complex

➡ **Only lepton+neutrino decay is practical**





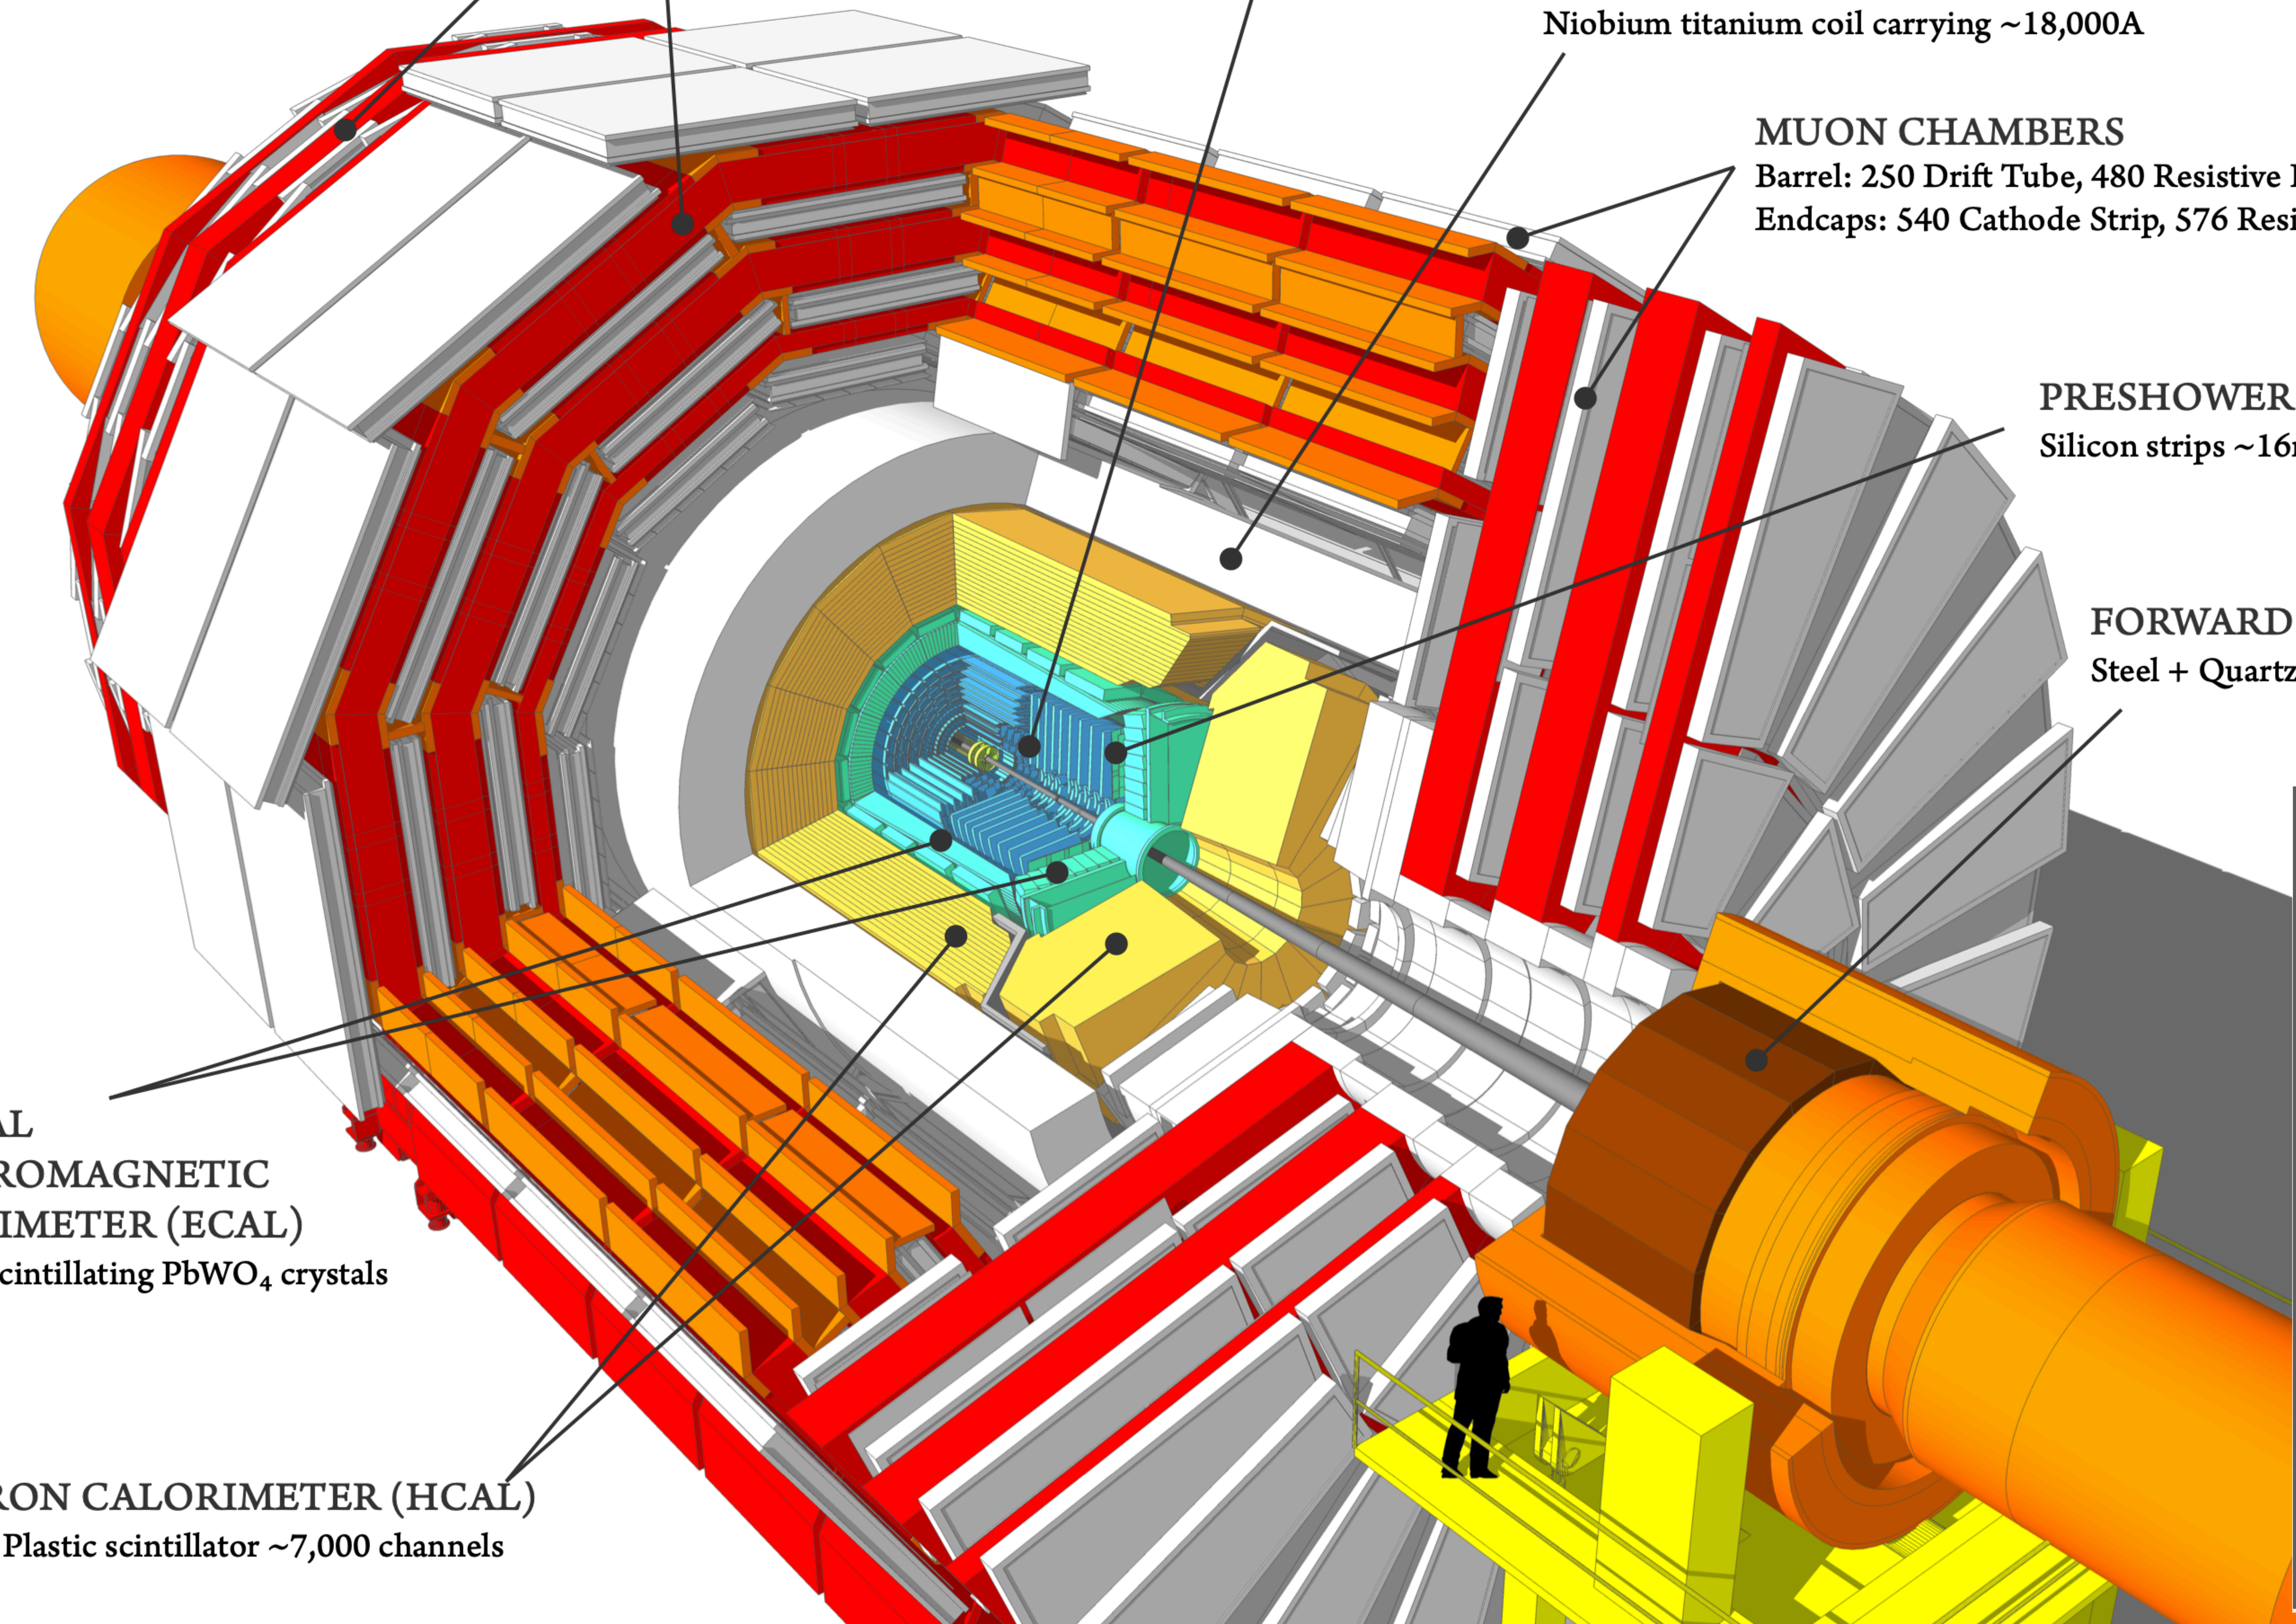
LEP (L3)
vs.
LHC (CMS)



https://cds.cern.ch/record/2865845

CMS DETECTOR

Total weight : 14,000 tonnes
Overall diameter : 15.0 m
Overall length : 28.7 m
Magnetic field : 3.8 T



STEEL RETURN YOKE
12,500 tonnes

SILICON TRACKERS
Pixel (100x150 μm) ~1m² ~66M channels
Microstrips (80x180 μm) ~200m² ~9.6M channels

SUPERCONDUCTING SOLENOID
Niobium titanium coil carrying ~18,000A

MUON CHAMBERS
Barrel: 250 Drift Tube, 480 Resistive Plate Chambers
Endcaps: 540 Cathode Strip, 576 Resistive Plate Chambers

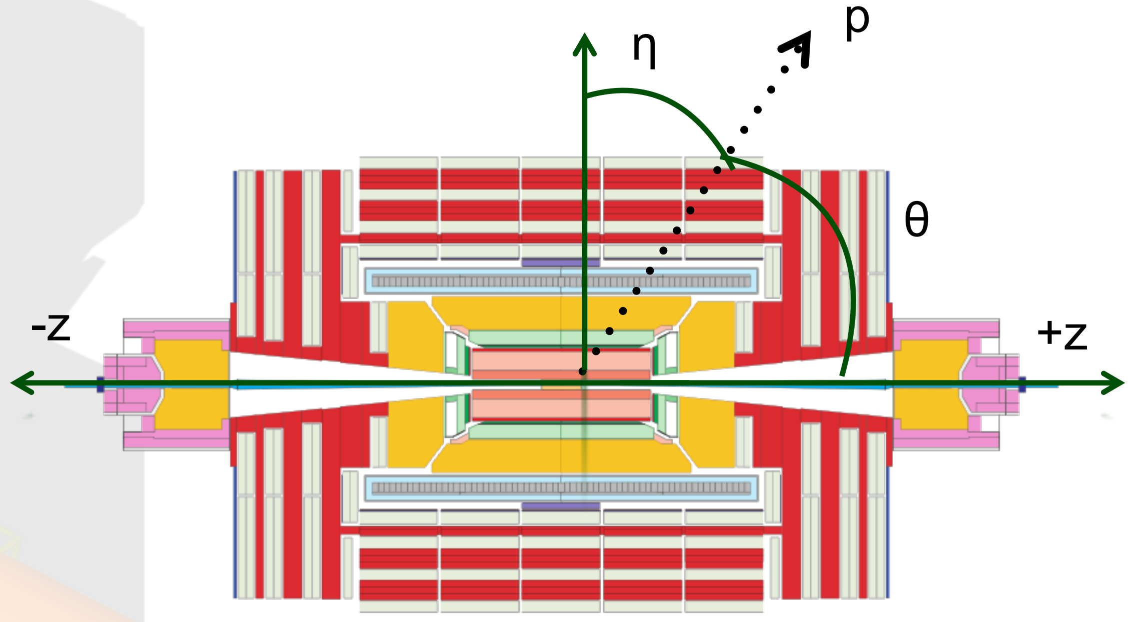
PRESHOWER
Silicon strips ~16m² ~137,000 channels

FORWARD CALORIMETER
Steel + Quartz fibres ~2,000 Channels

CRYSTAL ELECTROMAGNETIC CALORIMETER (ECAL)
~76,000 scintillating $PbWO_4$ crystals

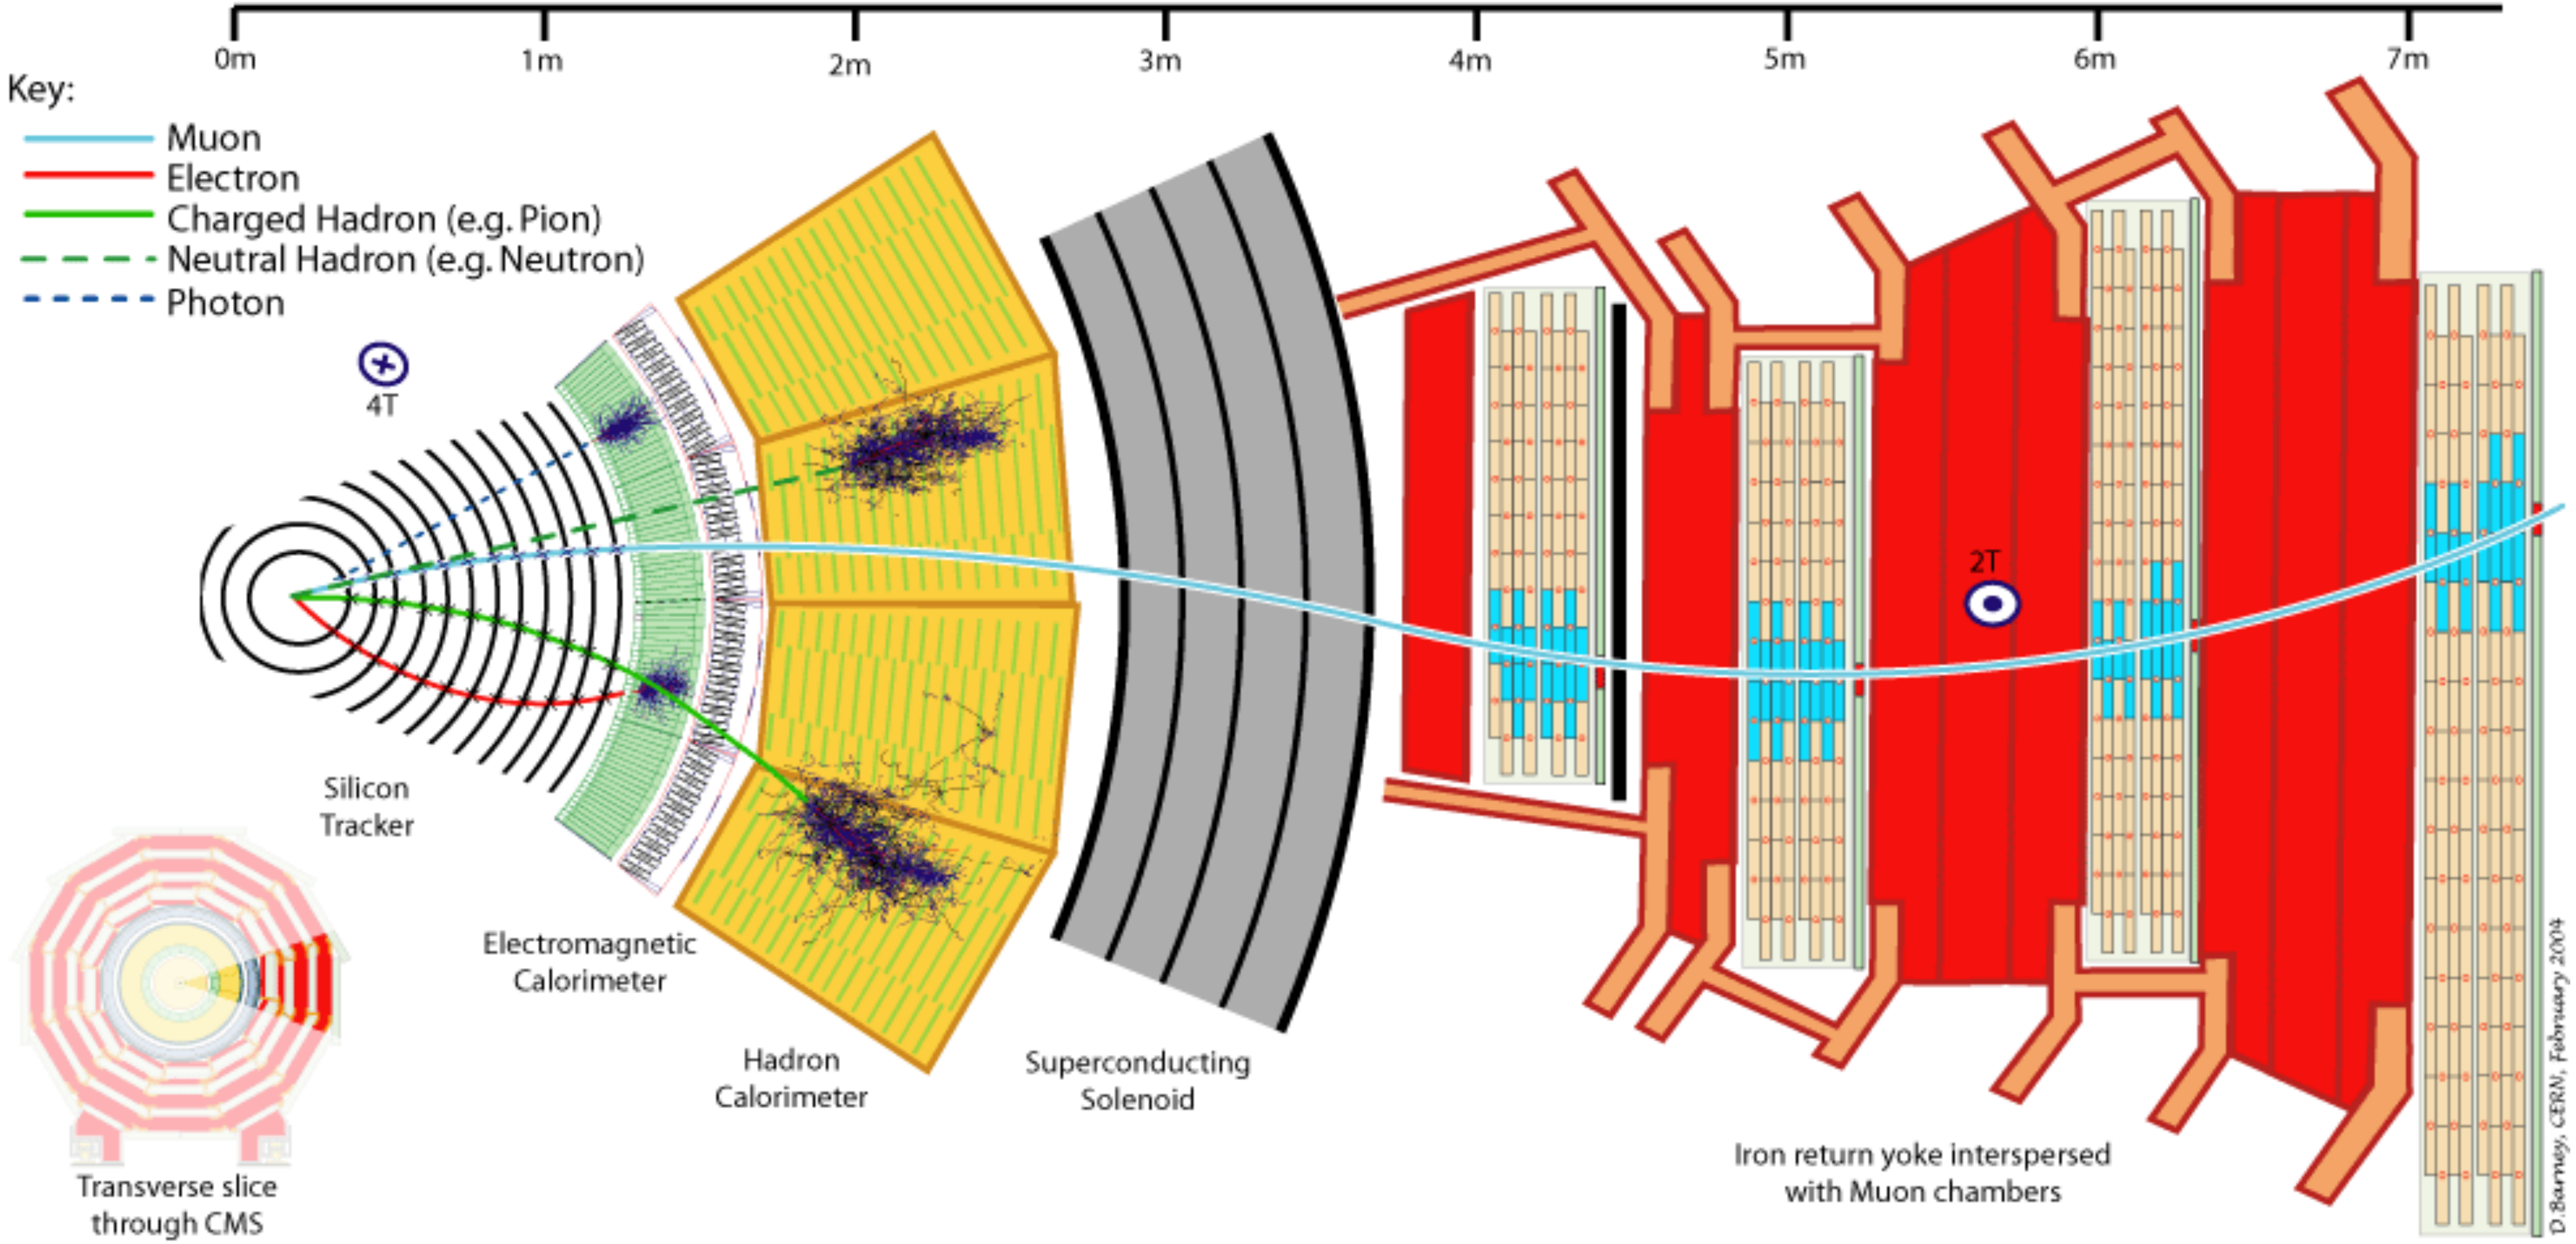
HADRON CALORIMETER (HCAL)
Brass + Plastic scintillator ~7,000 channels

$$\vec{r} = r(\phi, \eta, z)$$



$$\eta = -\ln\left[\tan\left(\frac{\theta}{2}\right)\right]$$

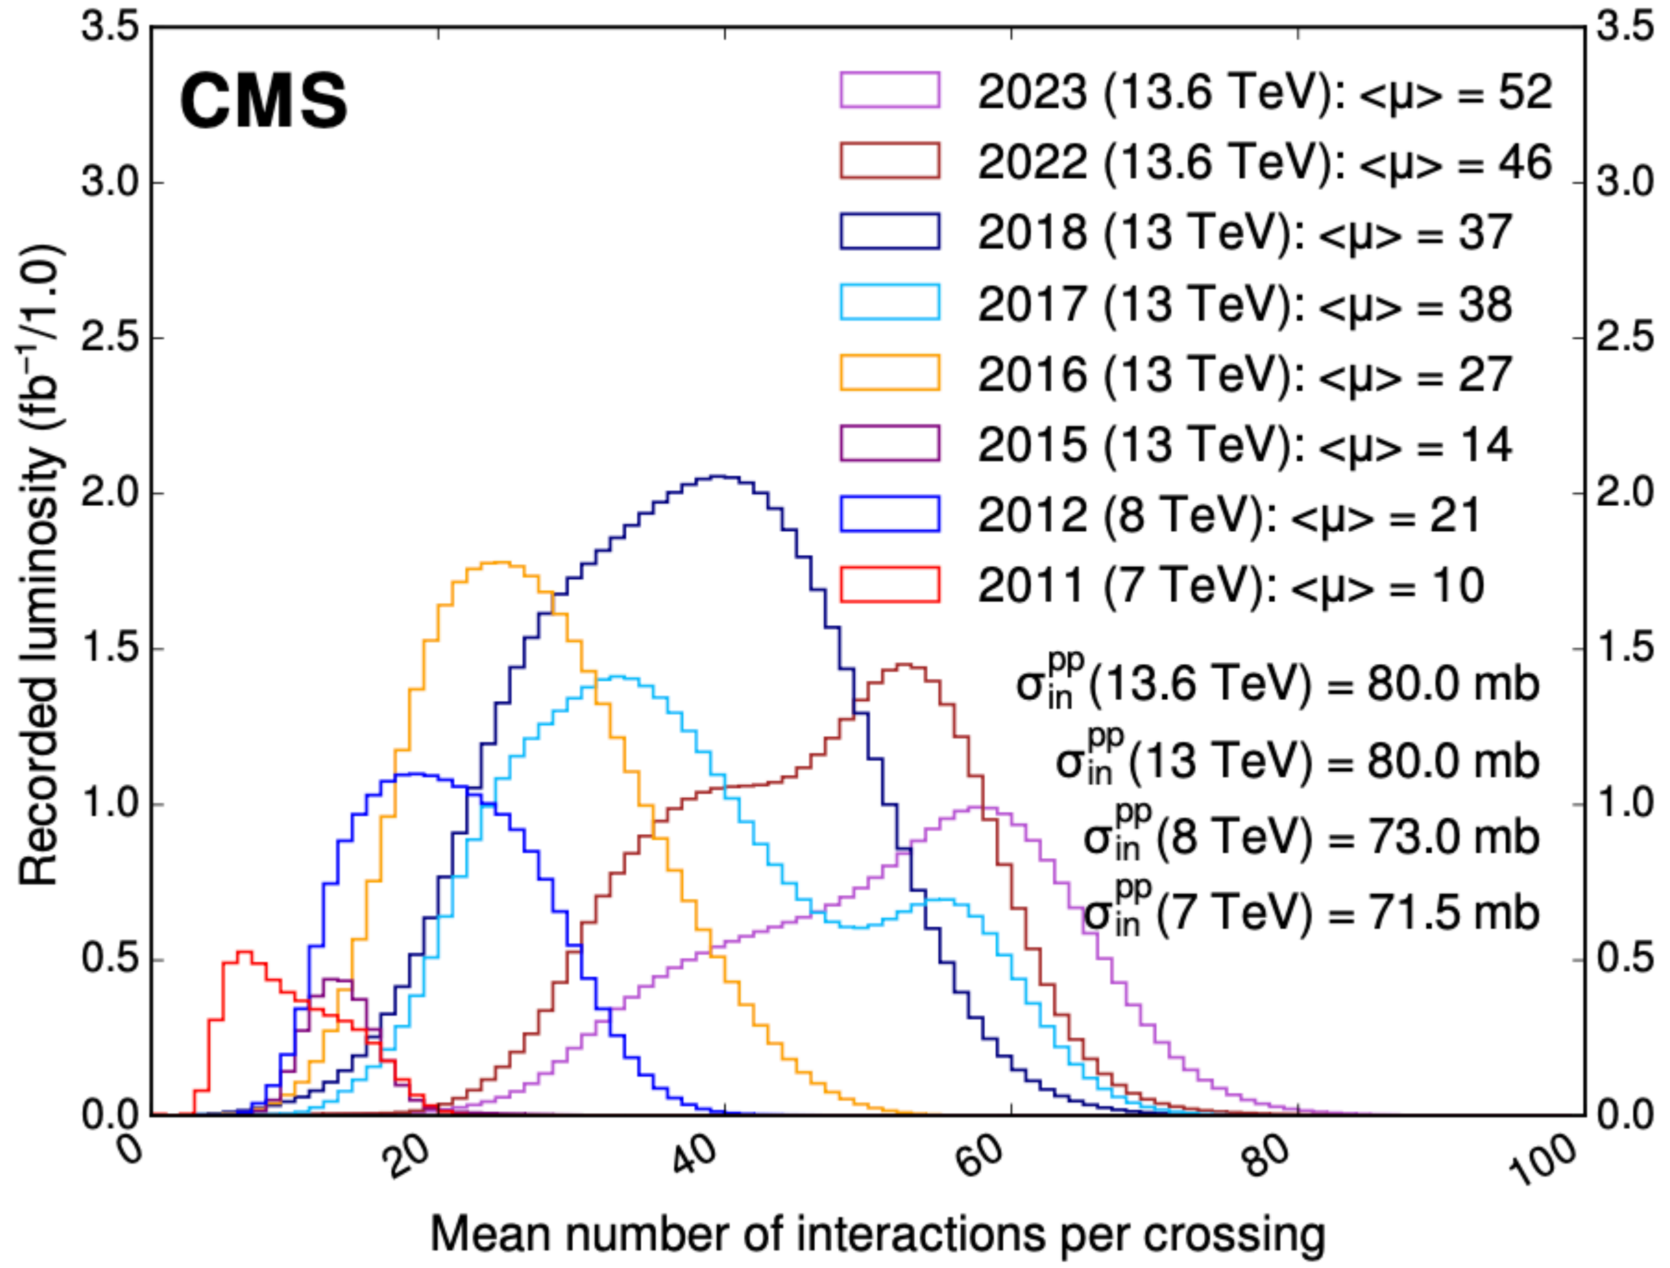
Particle reconstruction with the CMS detector

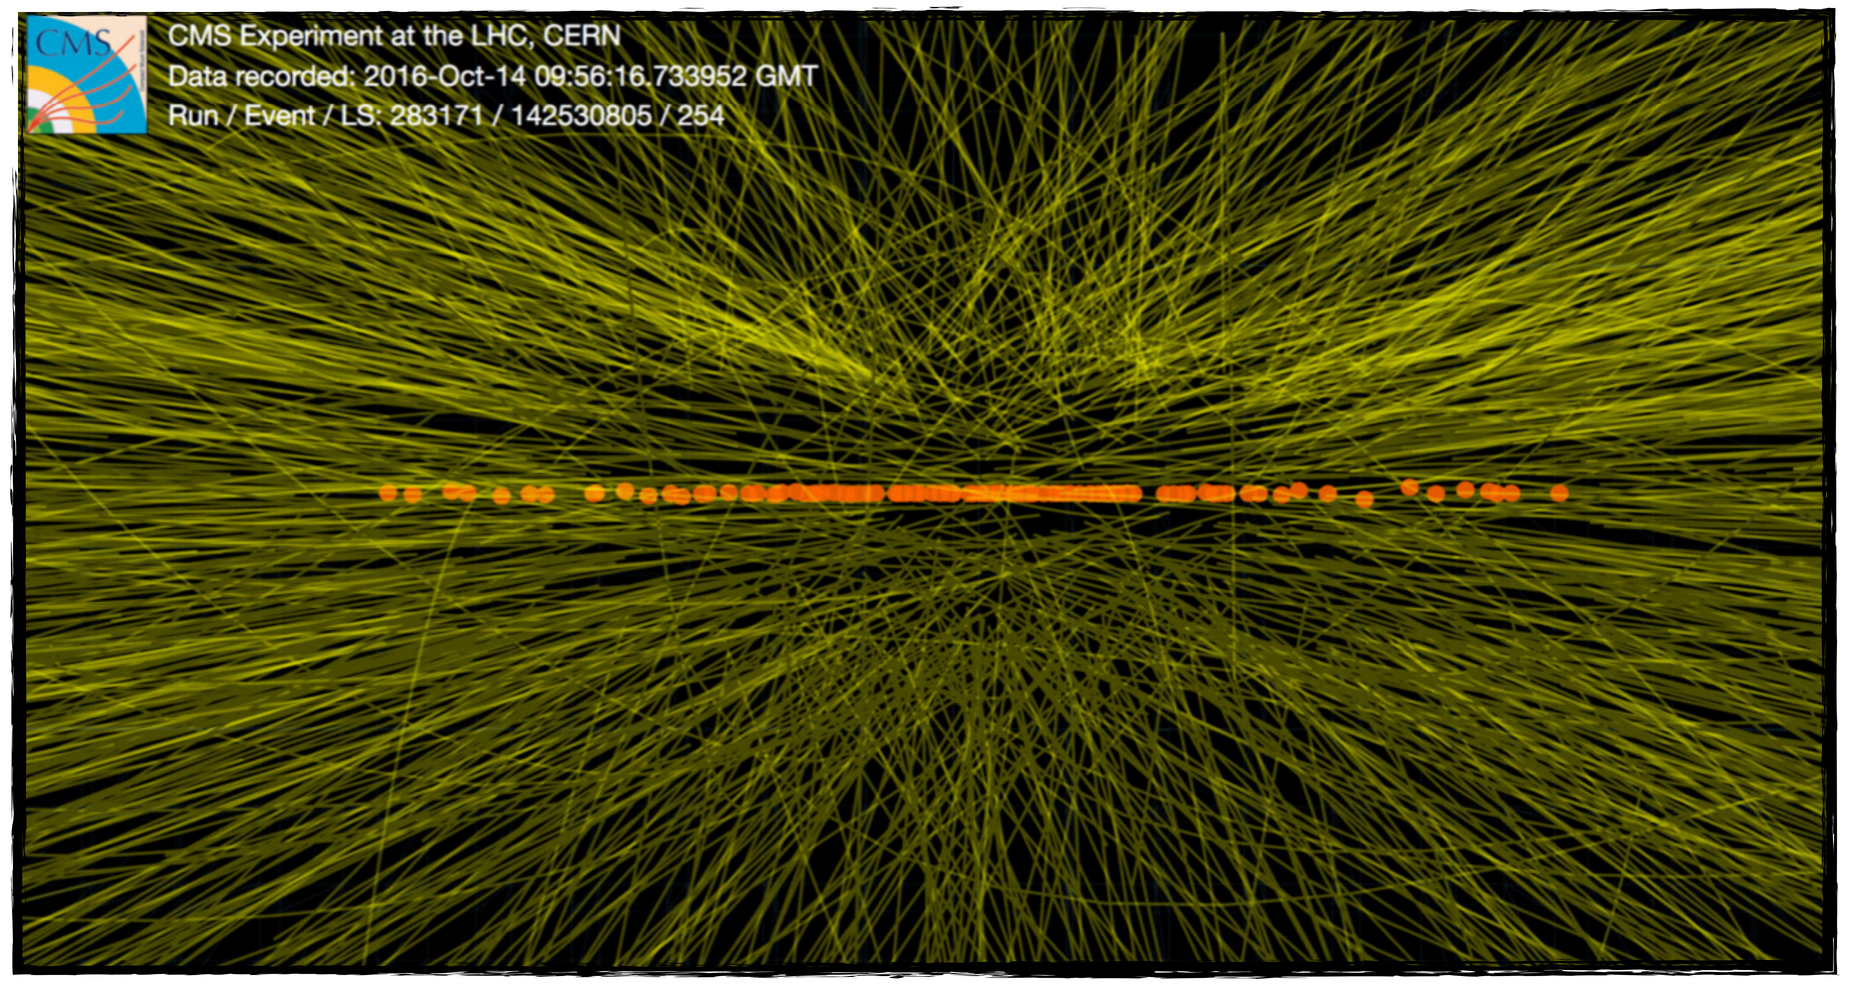


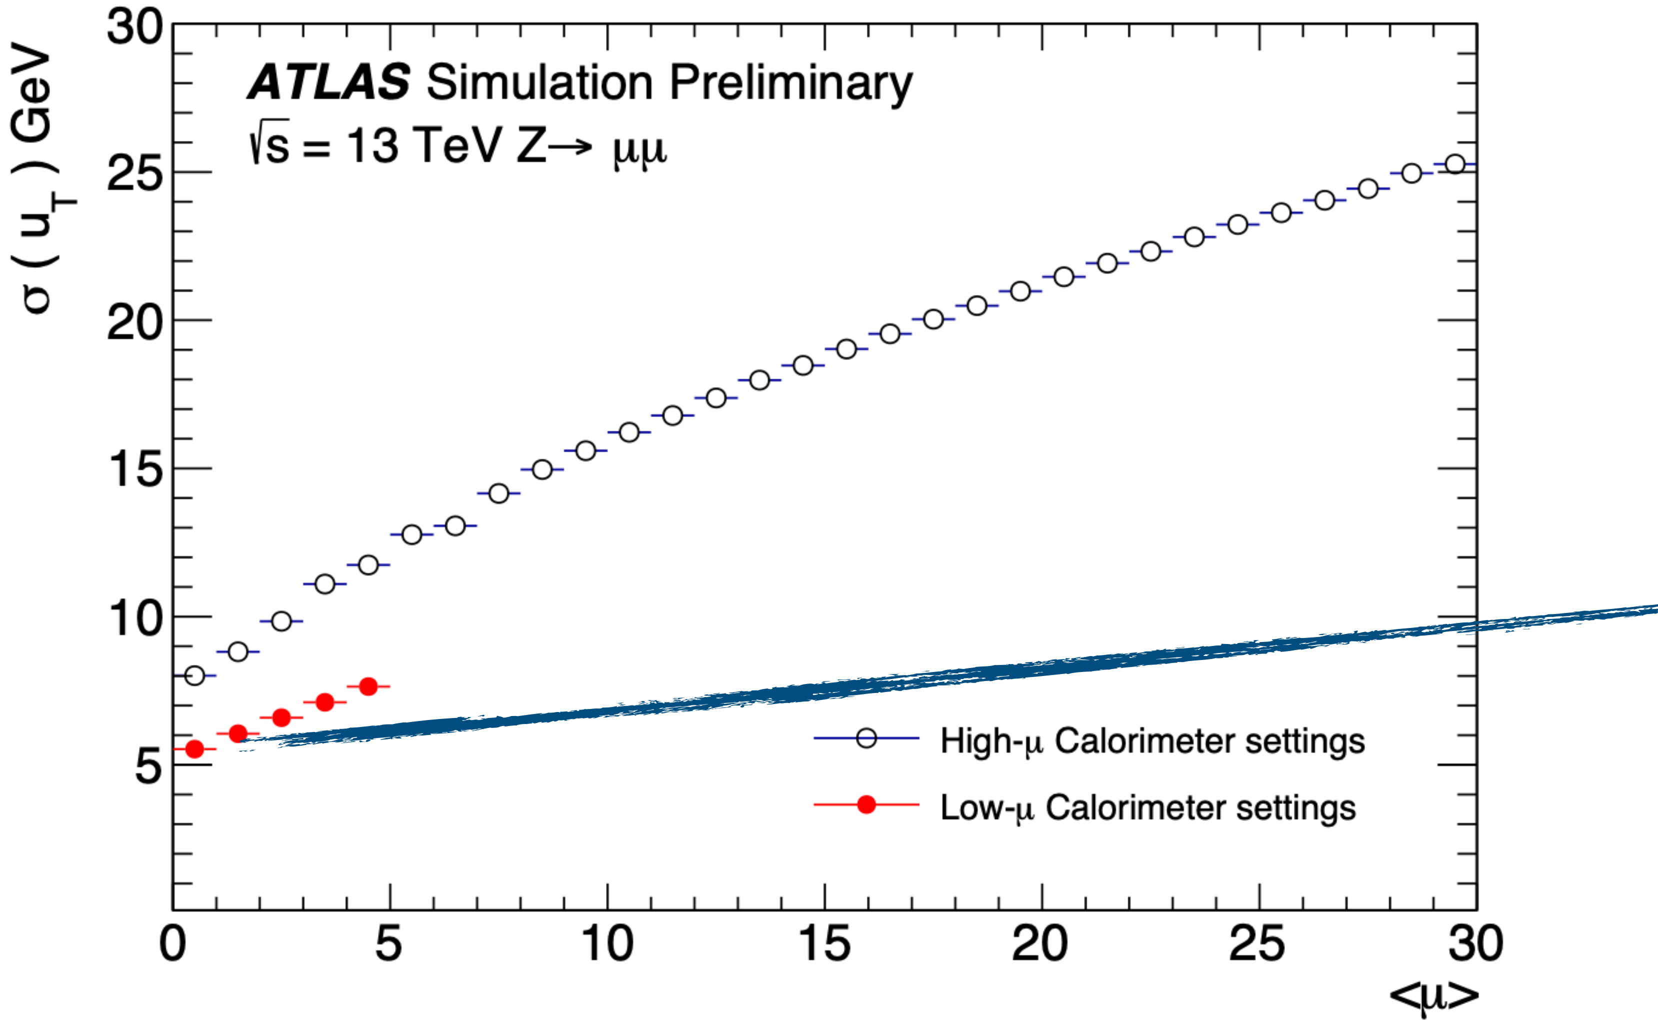
- high B-field, excellent silicon tracker + muon system $\Longrightarrow$ precise μ measurement
- Hadronic jets from clustering individual particle candidates
- Neutrino transverse momentum from conservation of momentum

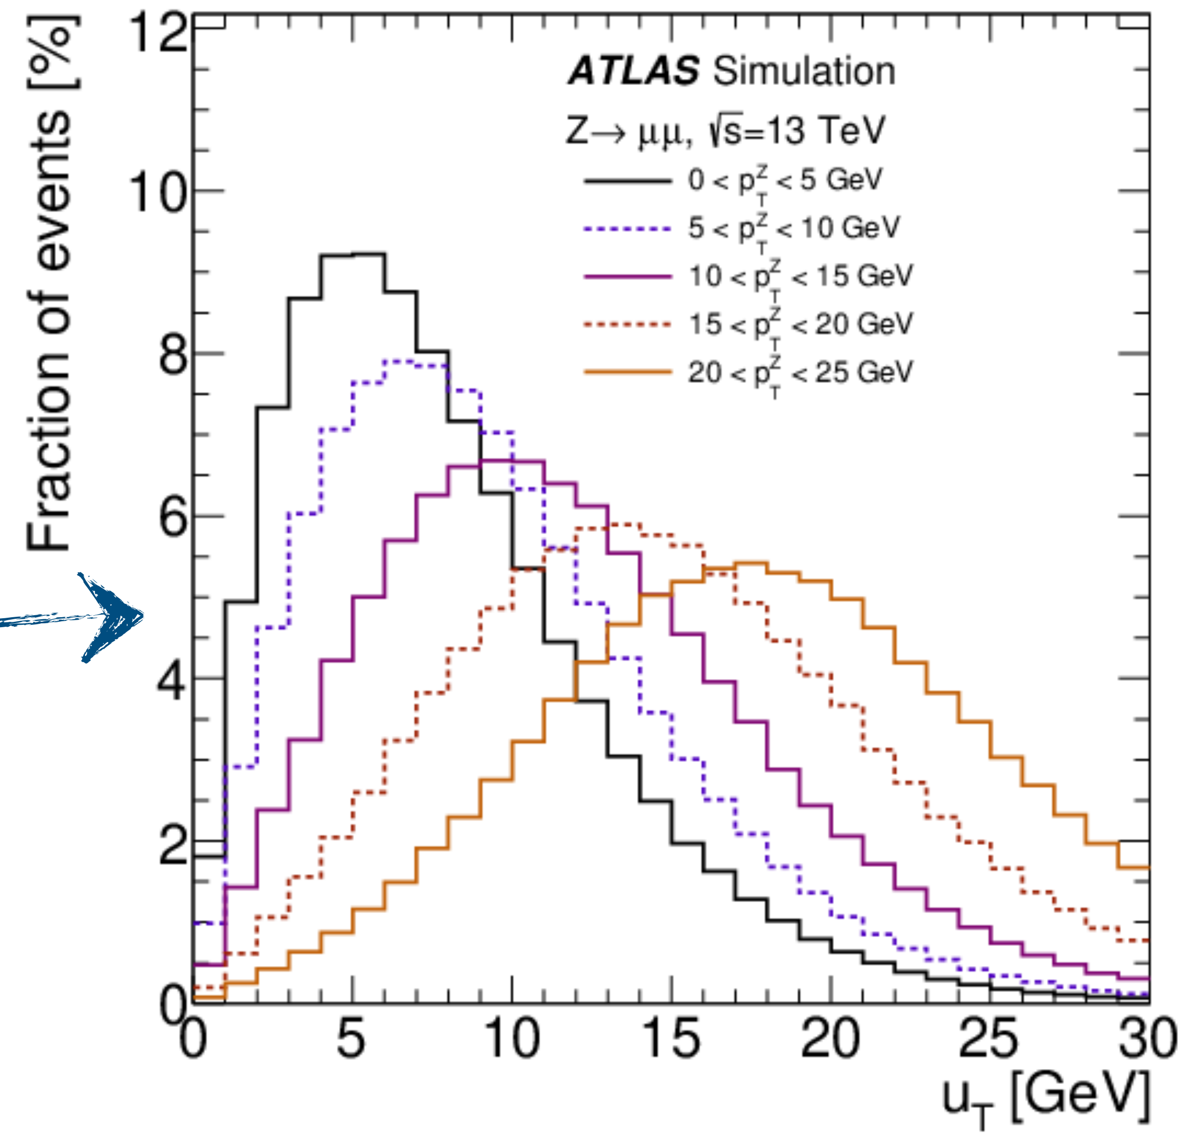
Pileup

- Multiple pp interactions in one LHC bunch crossing
  - Critical to the LHC push to high luminosity, but not “for free”
- **“Is pileup really such a big deal?”** — Anonymous theory colleague
  - Most measurements: it’s worth the hit
  - Precision measurements: it’s a huge challenge!
- More stuff in the detector ⟹ more chances for confusion (e.g., tracks built from wrong hits), higher chance to mis-measure
  - Balancing act between lumi. and performance
  - **Dedicated low-pileup runs** offer unique opportunities

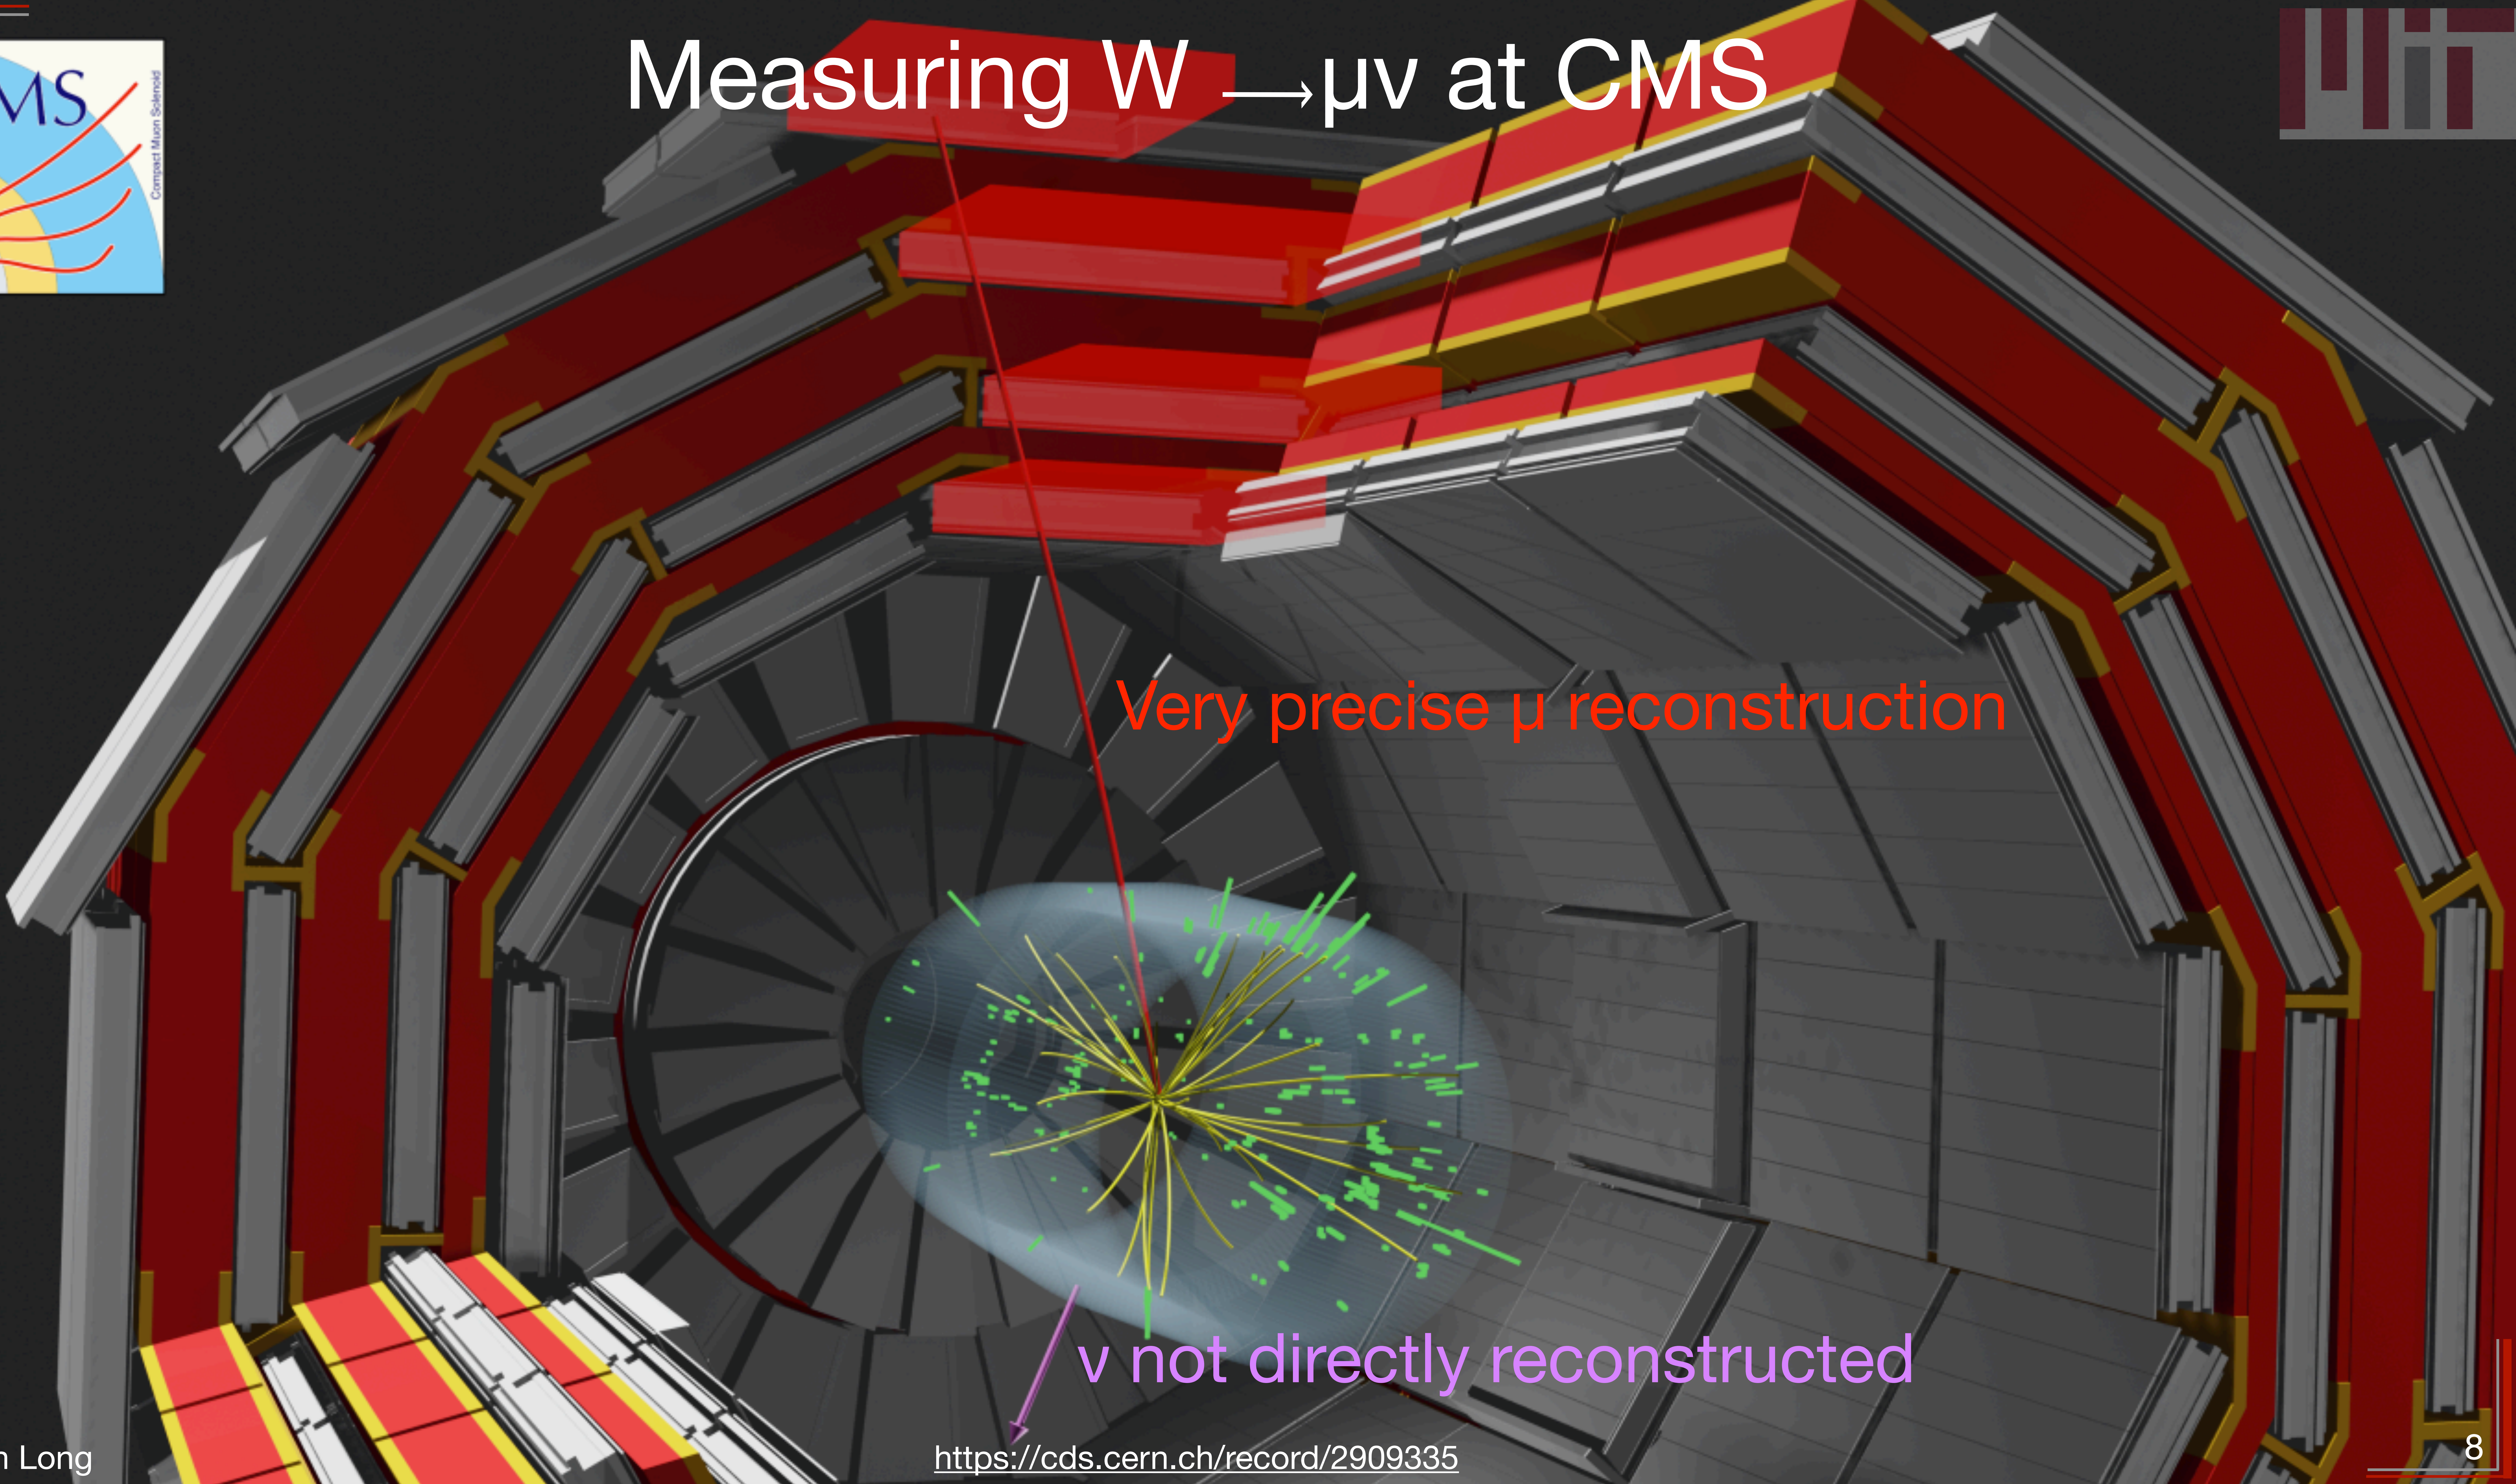








Measuring W →μν at CMS

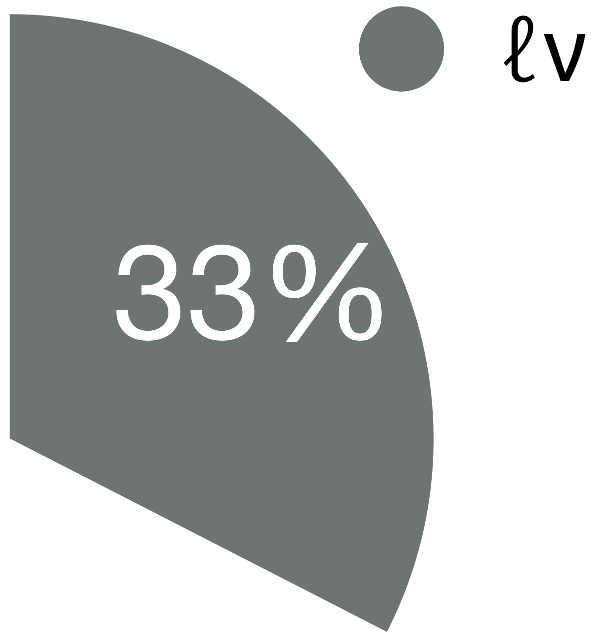


Very precise μ reconstruction

ν not directly reconstructed

https://cds.cern.ch/record/2909335

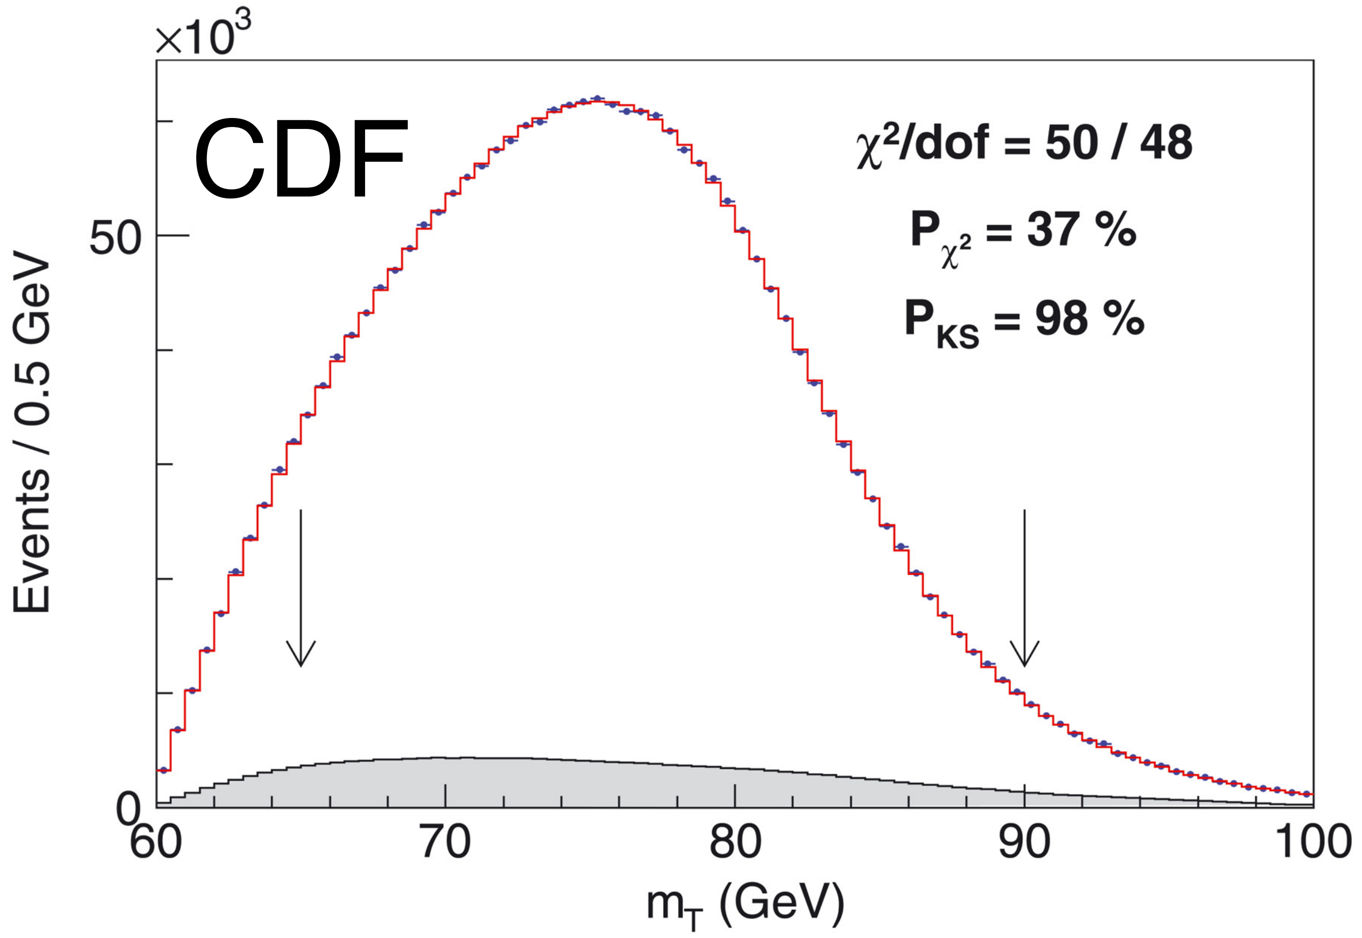
Measuring m_W at hadron colliders

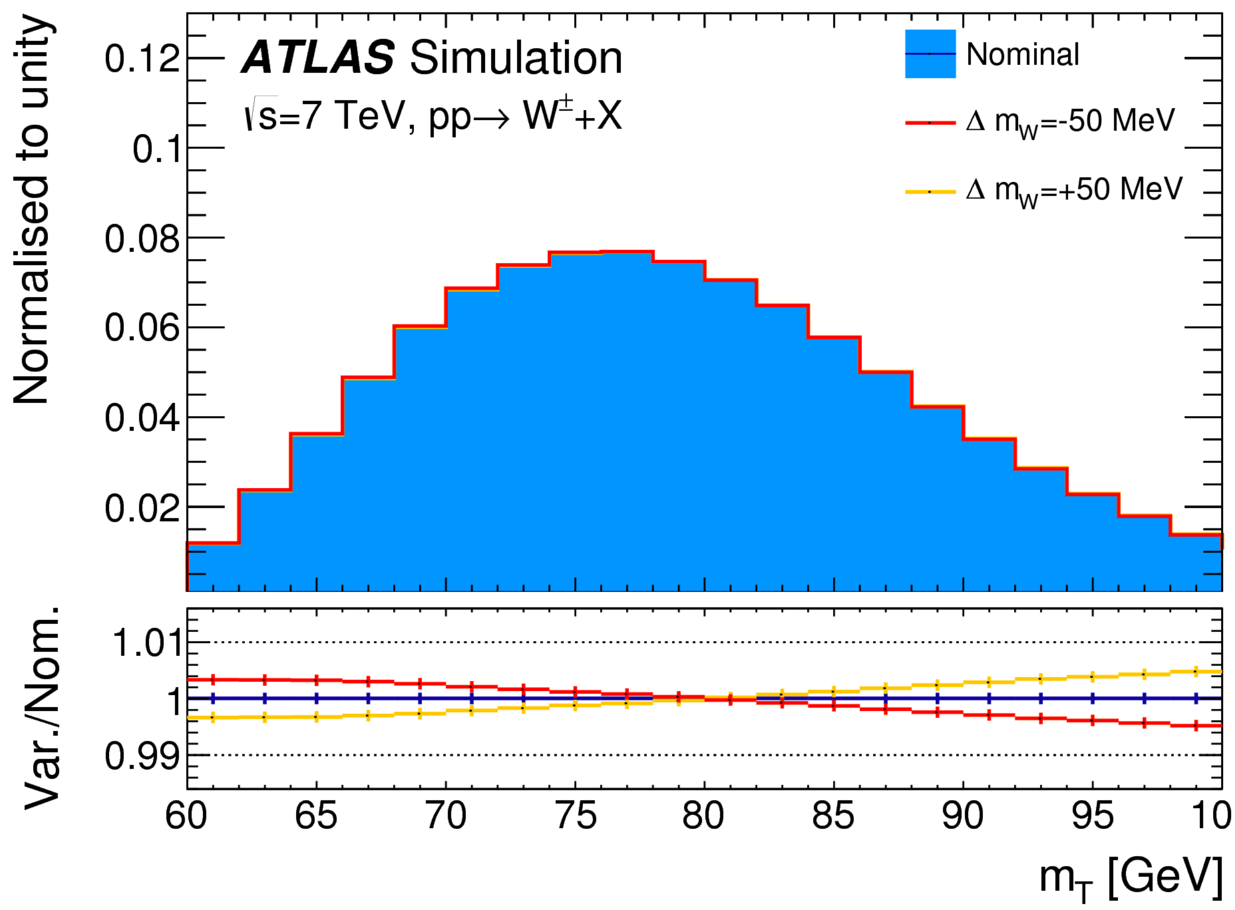


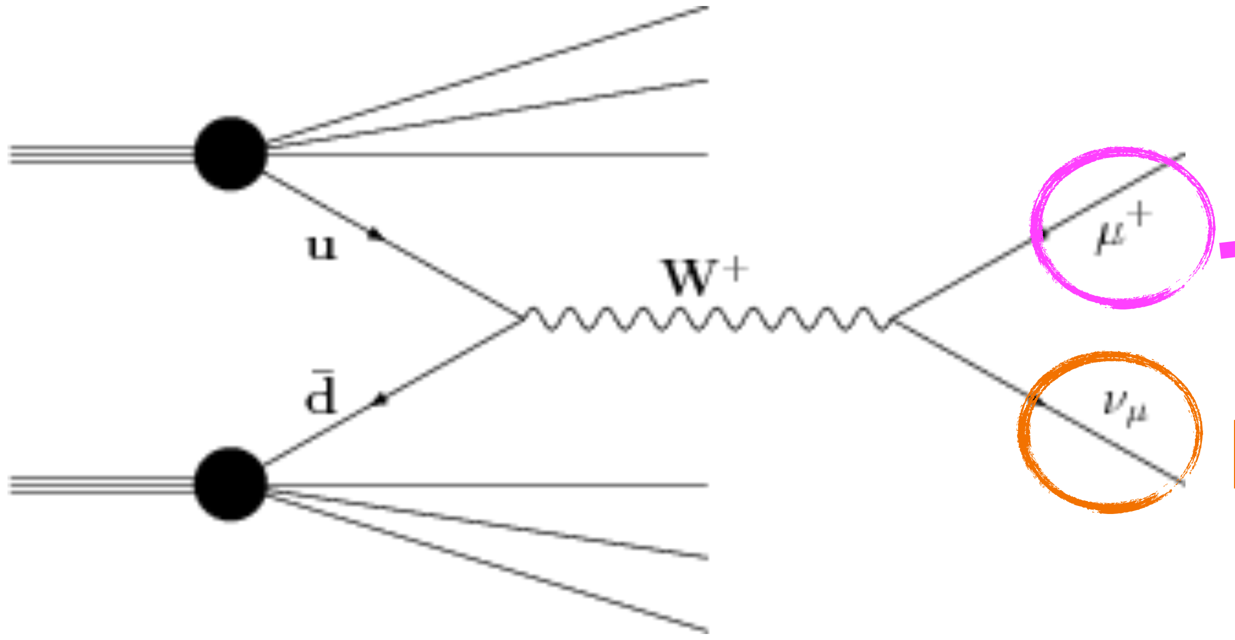
- Rely on observable(s) sensitive to m_W built from measurable objects
  - Requires subpercent-level control of theoretical and exp. inputs

$$m_T^W = \sqrt{2\, p_T^{\mu}\, p_T^{\mathrm{miss}}\, (1 - \cos \Delta\phi_{\ell\nu})}$$

- Jakobian peak at m_W
- Small dependence on p_T^W
- Precise p_T^{miss} very difficult at LHC

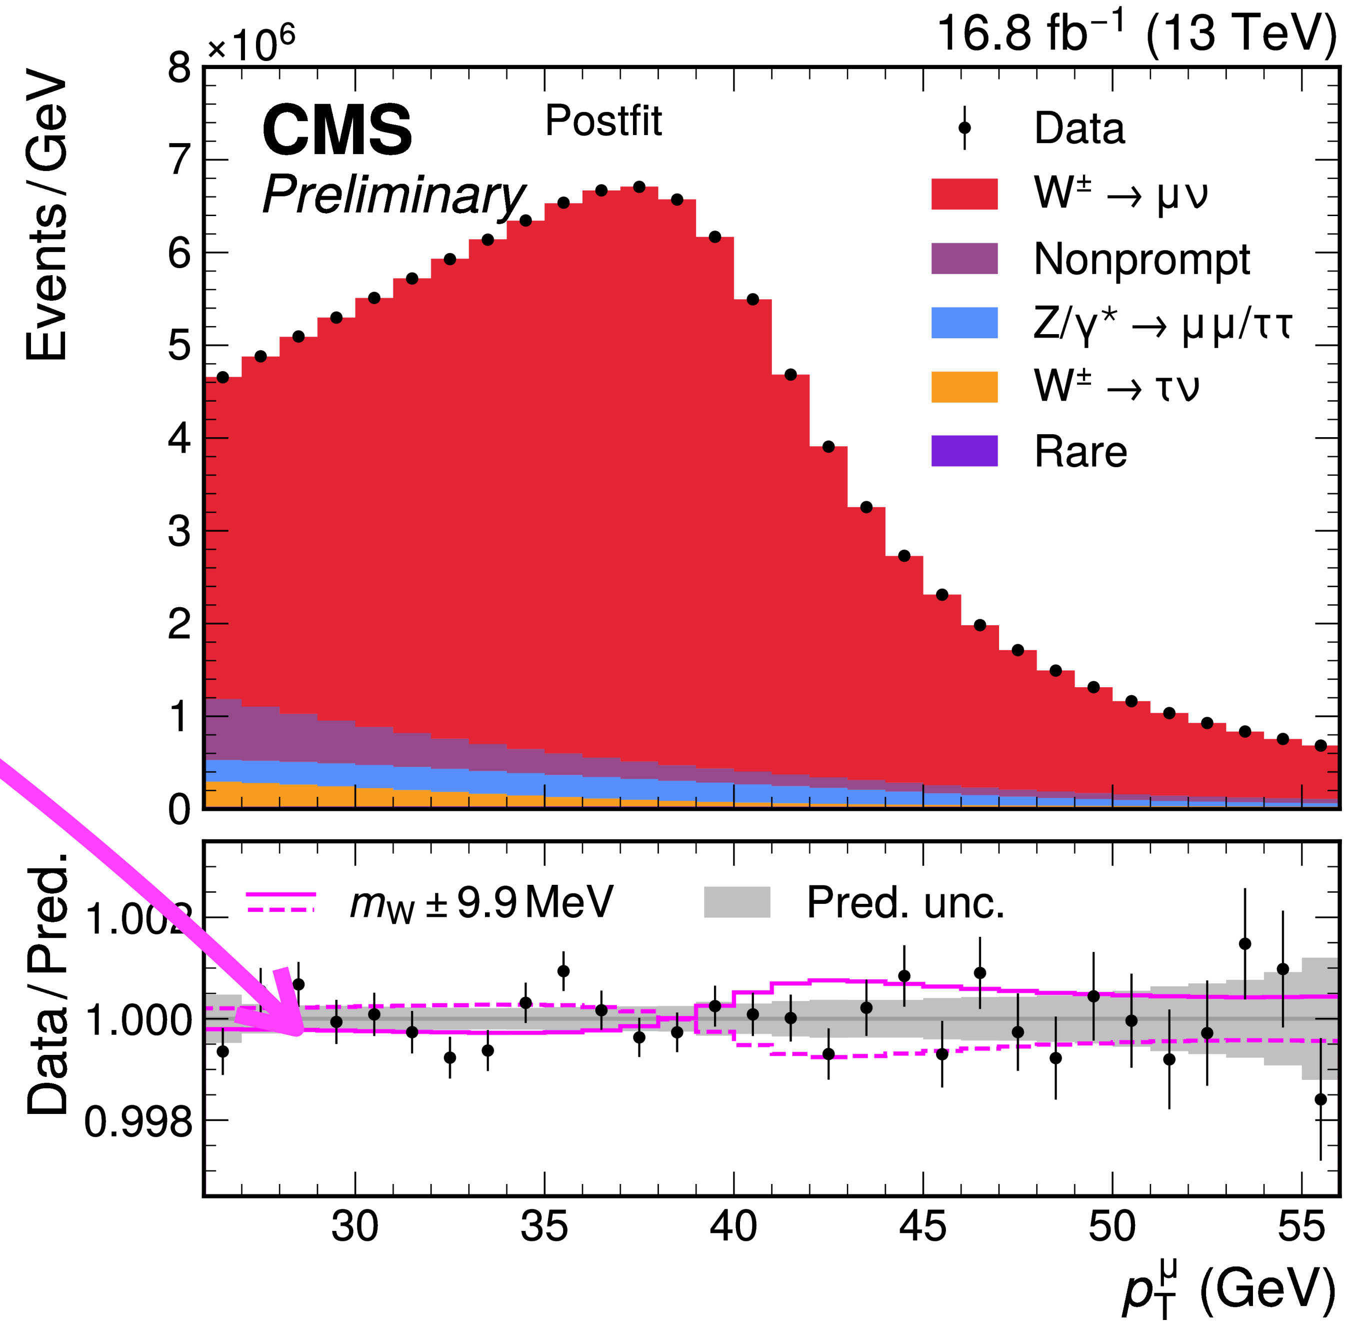






Escapes detection
⇒Missing transverse momentum

< per mille precision

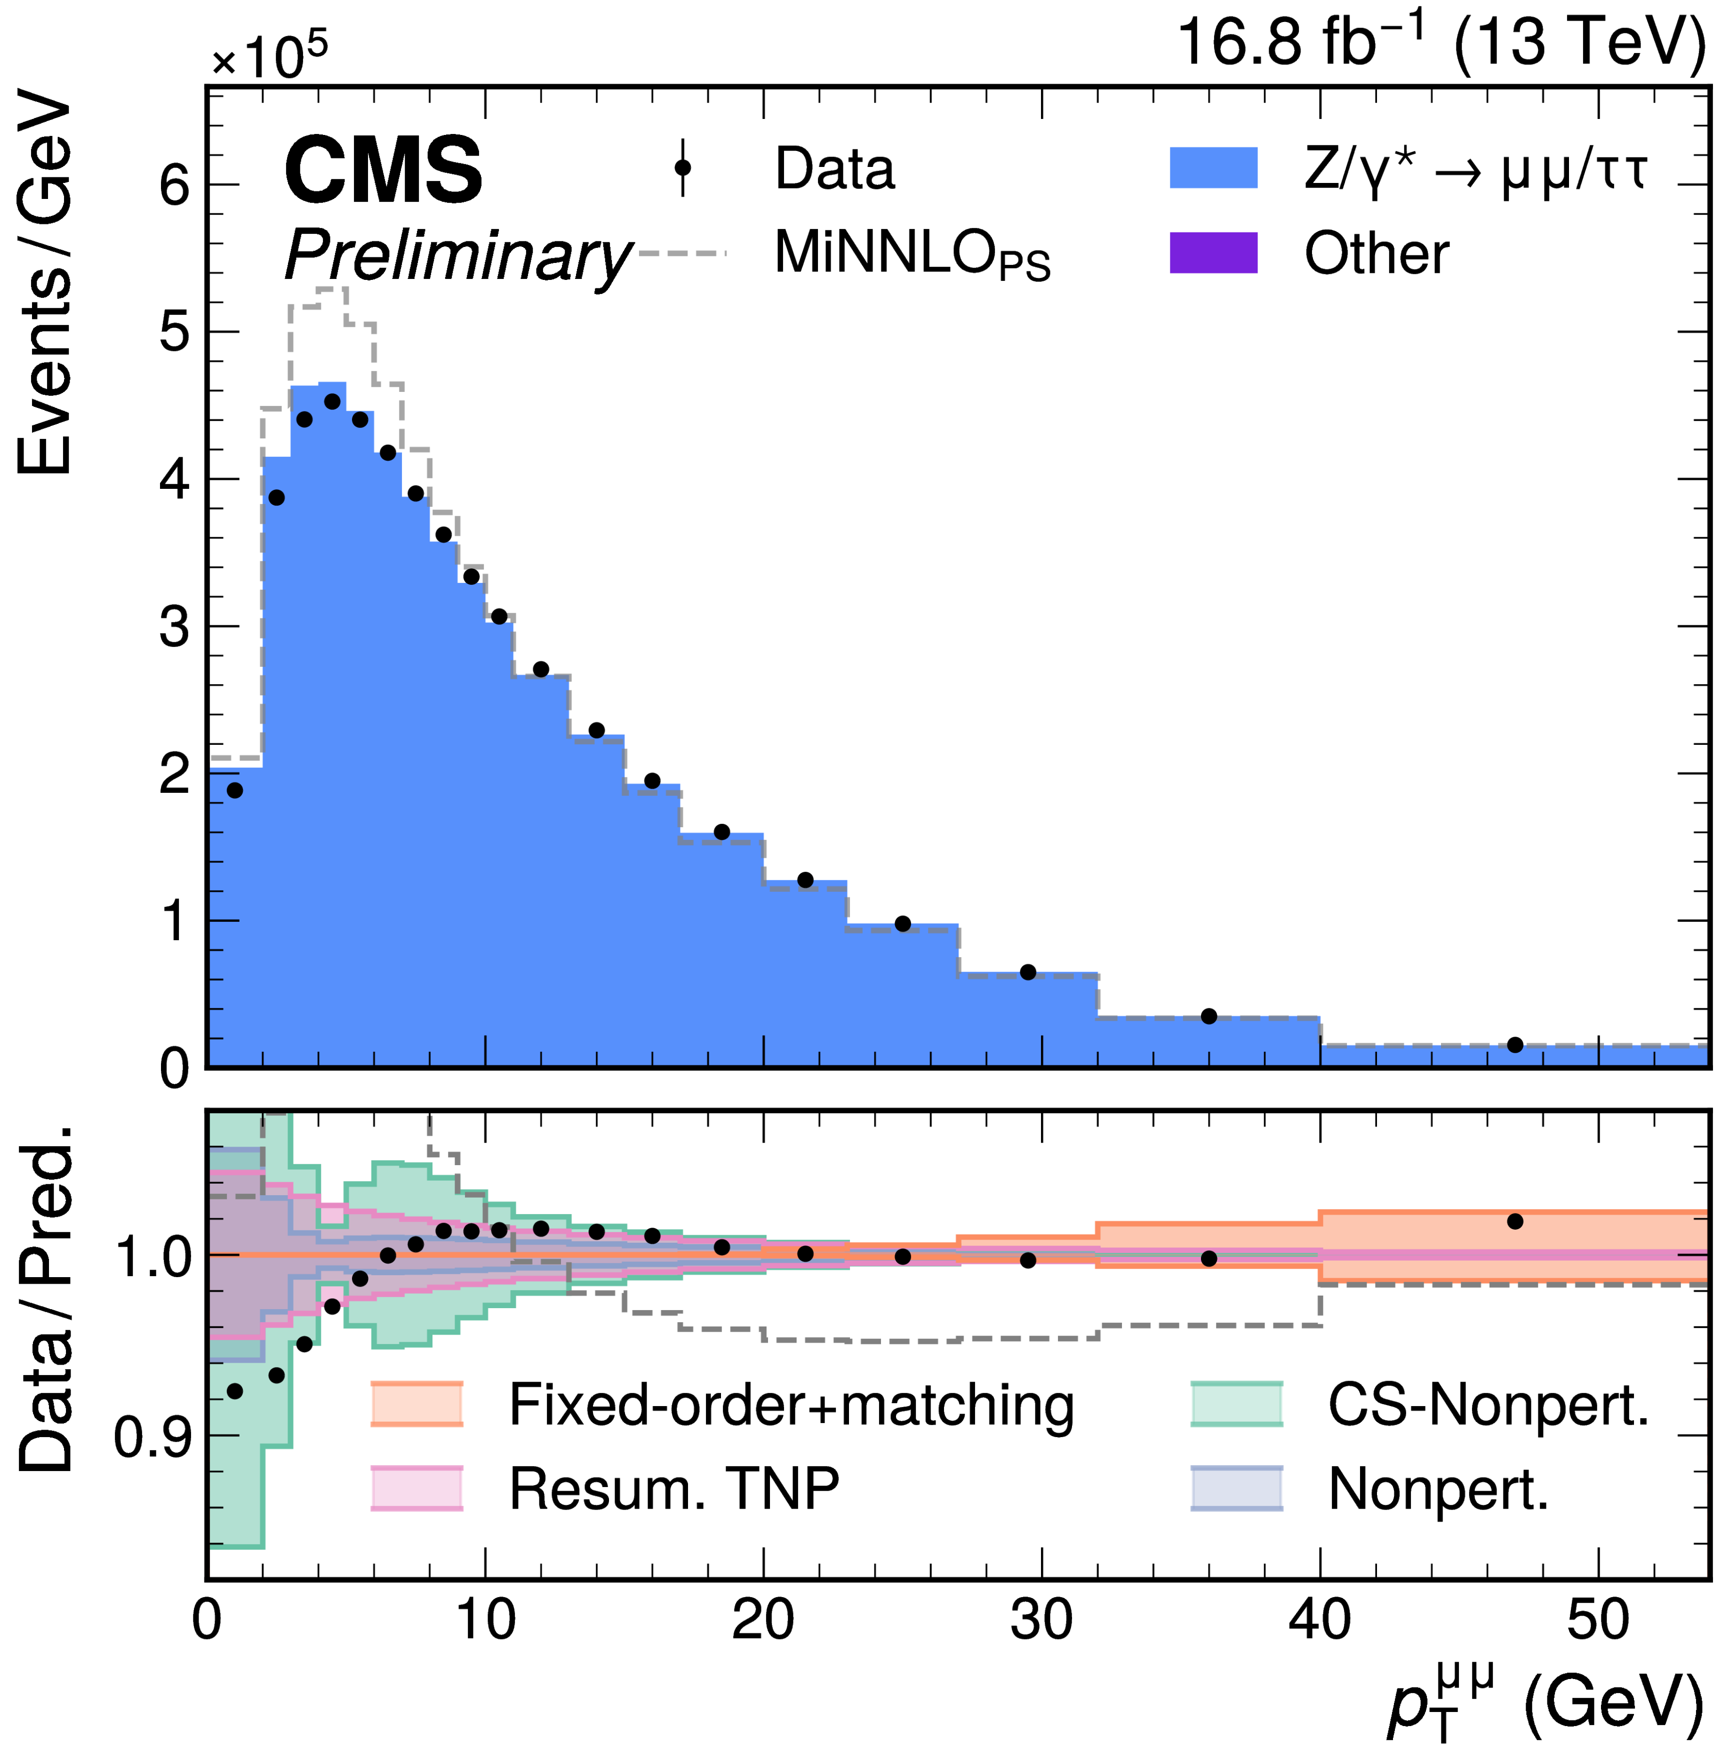


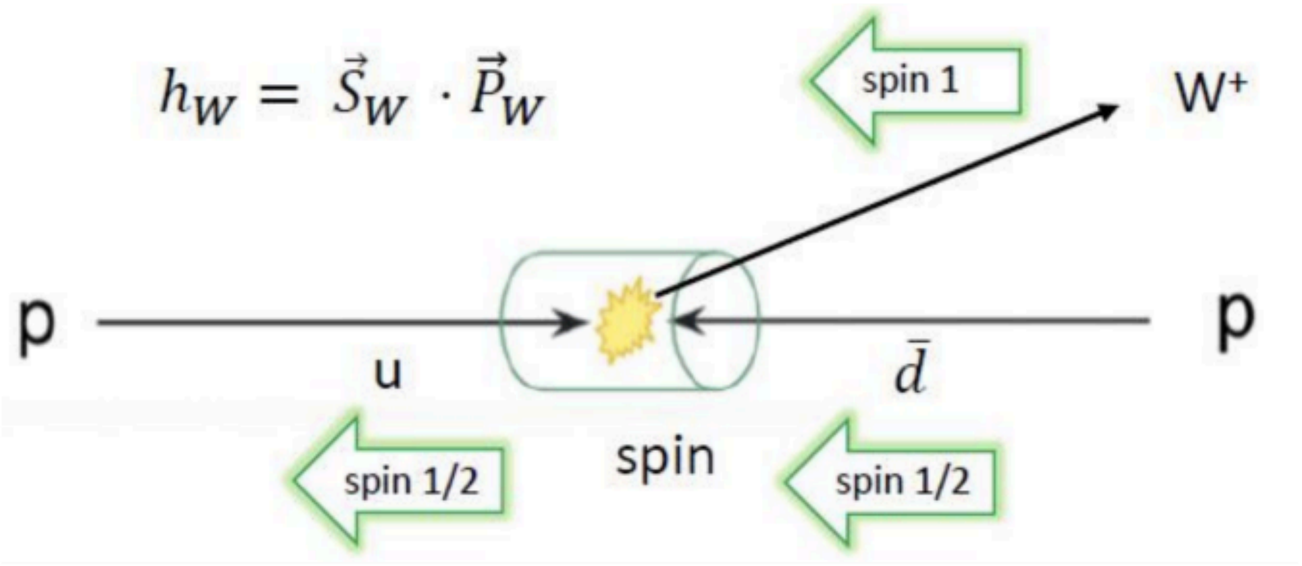
- Mass is equally divided between μ and ν
- In rest frame, $p^\mu \sim m_W/2$
- In lab frame, smeared by p^W

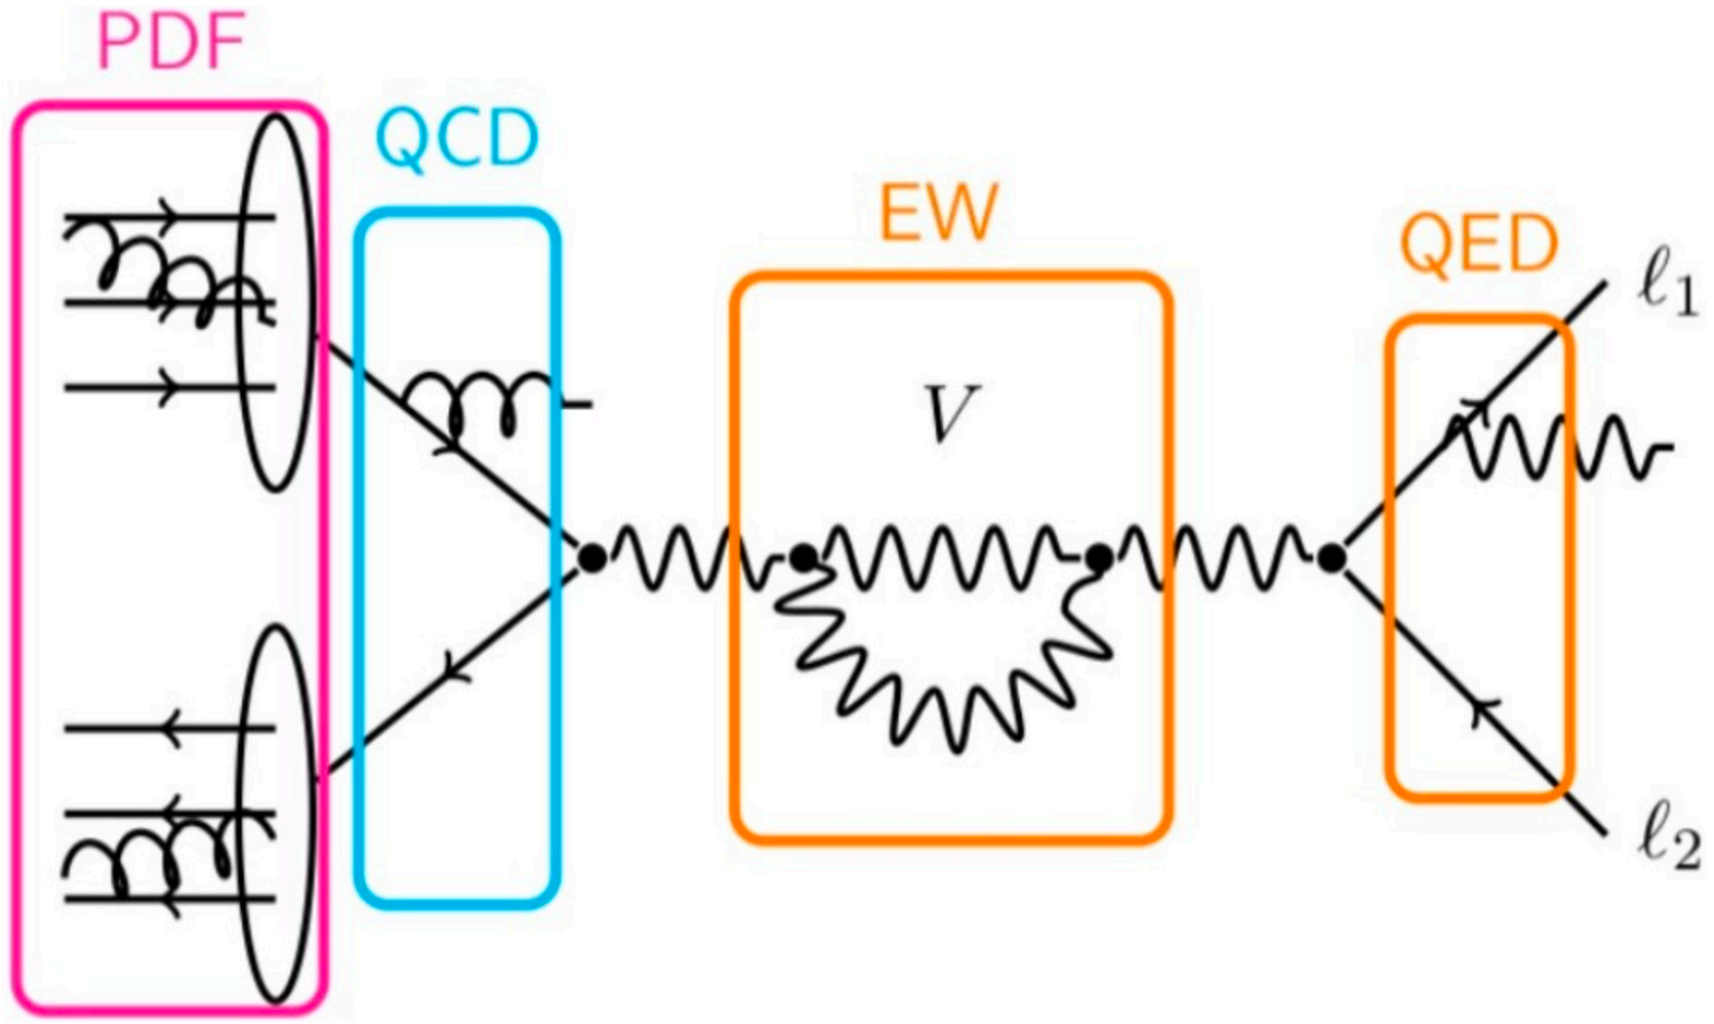
➡knowledge of W momentum required

W and Z boson production at the LHC

- Final state is not fully reconstructed ⟹ measurement is highly sensitive to W (Z) production
  - Many similarities between W and Z, but also important differences (e.g., quark flavours)
- Non-zero p_T^V due to gluon radiation from colliding quarks
  - Cannot be measured with high precision in LHC conditions
  - Subpercent-level precision in predictions immensely challenging
    - pQCD accurate at high p_T^V
    - Resum soft gluons for low/intermediate region
    - Non-perturbative motion of quarks important at low pTV
- Polarisation impacts kinematics of leptons from V decay
  - Largely determined by PDFs
- Electroweak corrections small, but relevant impact on V and ℓ

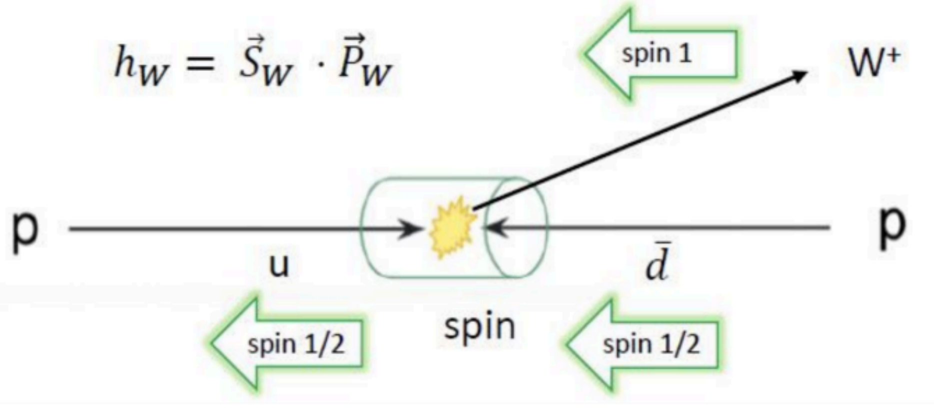


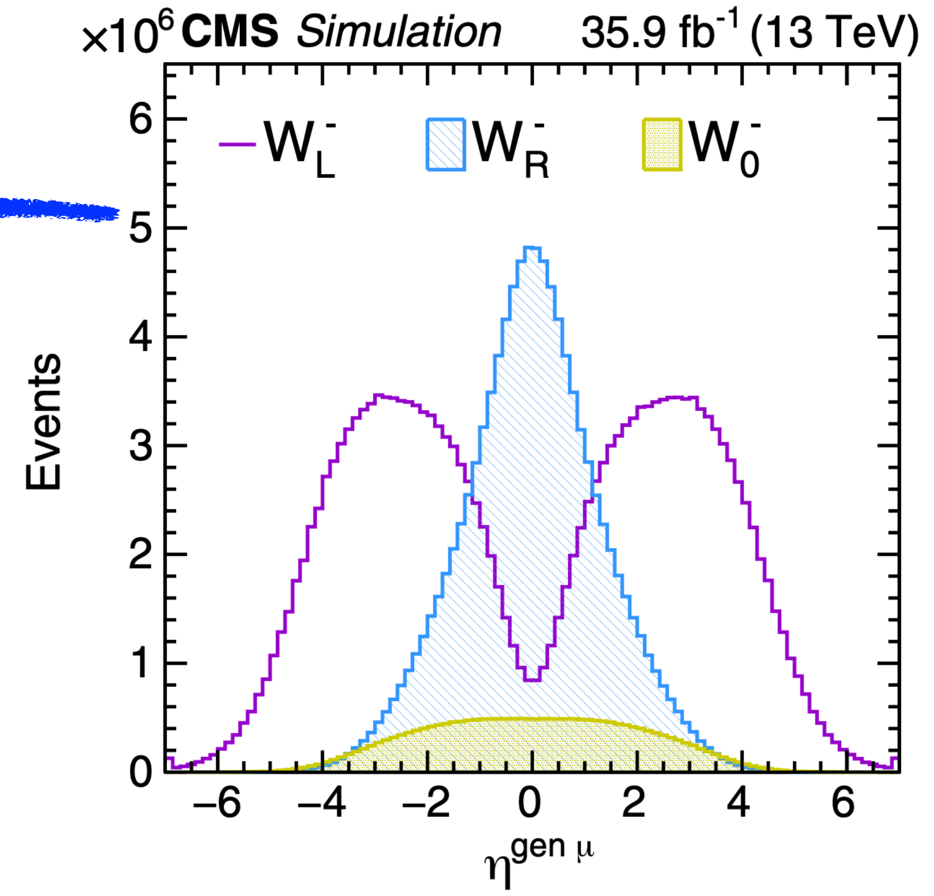


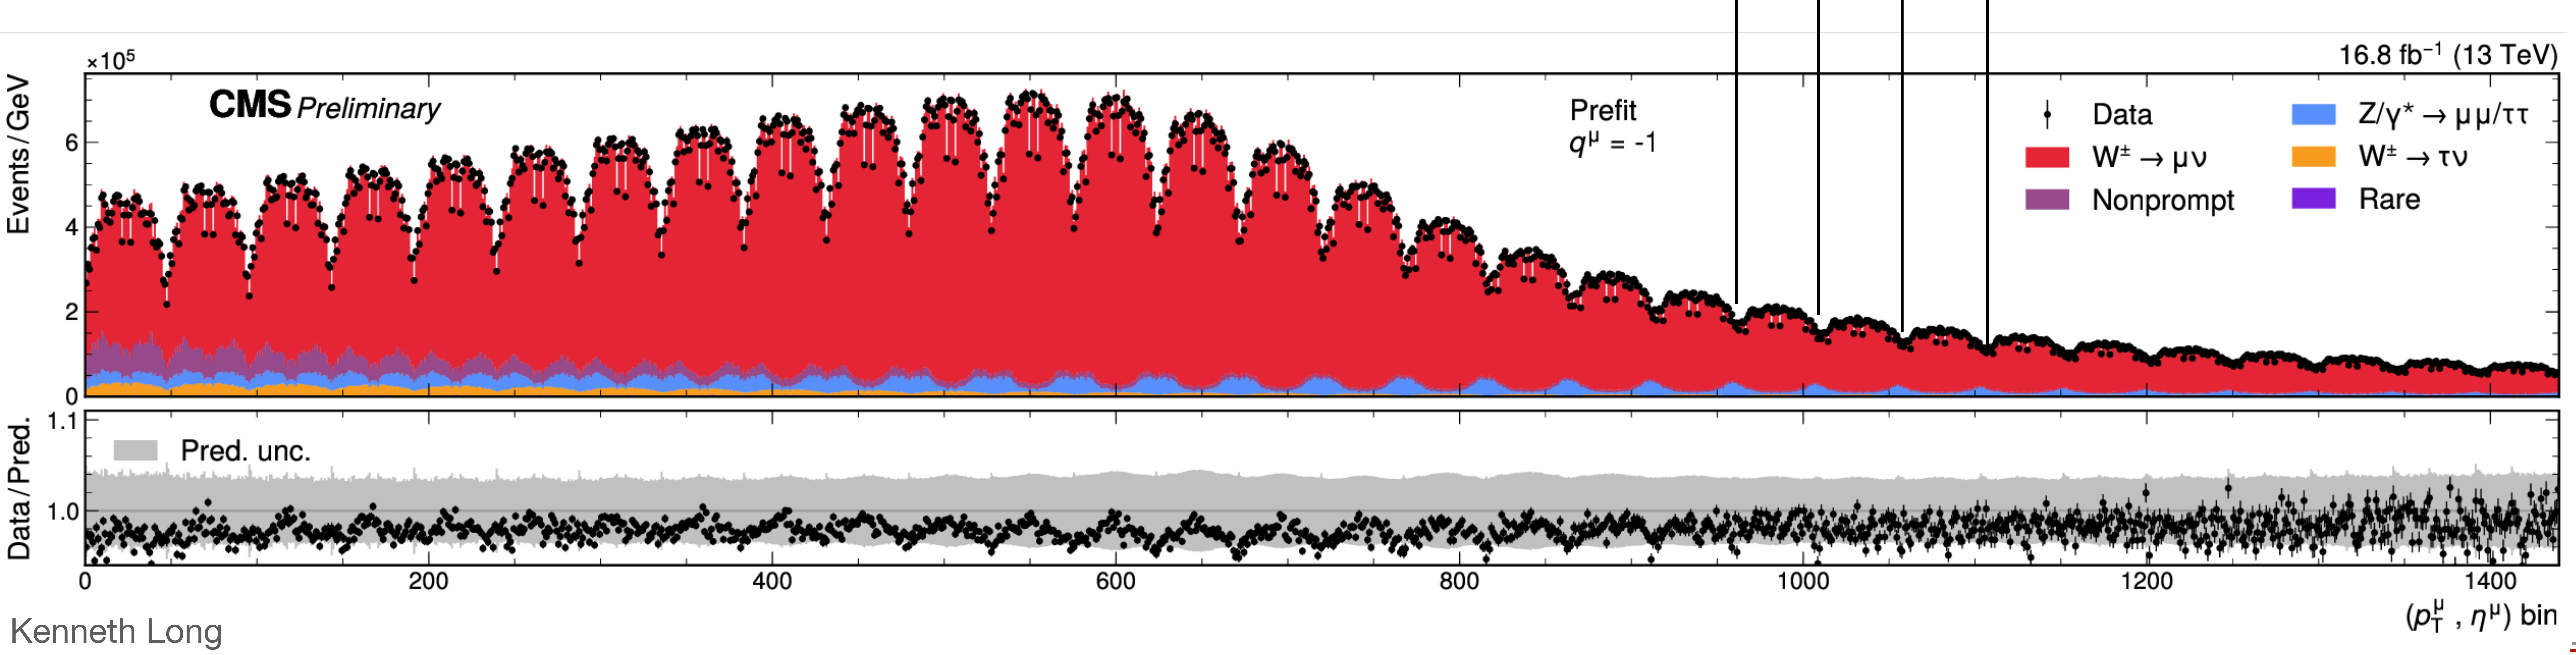


m_W strategy in CMS

- Focus on lepton kinematics
  - **Restrict to muon channel** (better calibration of momentum)
- **Data has strong constraining power**
  - 16.8 fb^{-1} subset of data collected in 2016 (~100 M selected W events)
  - Small subset of data, but largest-ever dataset for m_W measurement
  - In particular y^W (η^μ), is dependent on W helicity, which is largely determined by PDF ⟹ sensitivity to PDF from η^μ
- Extract mass from fit to (q^μ, η^μ, p_T^μ) distribution

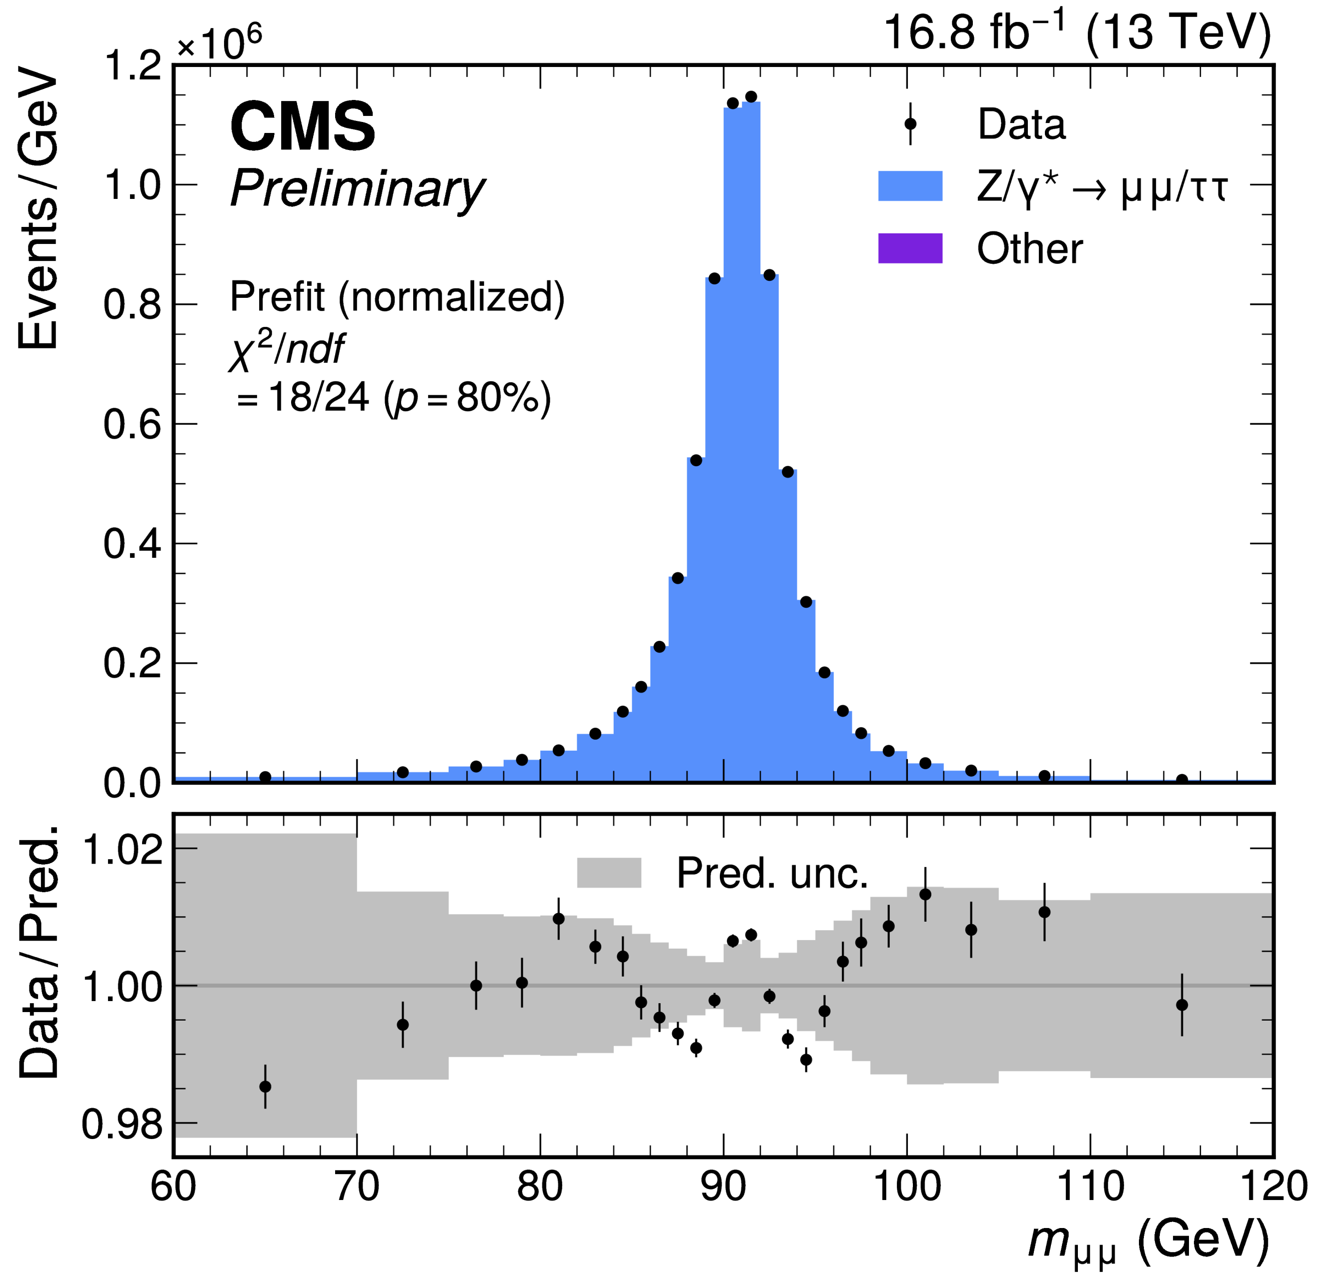






Validation with m_Z measurements

- **Crucial tool to validate m_W extraction**
  - Select Z events
  - Discard one lepton (add to p_T^{miss})
  - Measure m_Z with single-lepton kinematics
  - Cross-check with direct measurement of m_Z (and m_Z world average)
- Selection **maximally consistent with W analysis**
  - Take ℓ^+ (ℓ^-) in even (odd) events
  - Reject event if selected lepton is not the object that triggered event



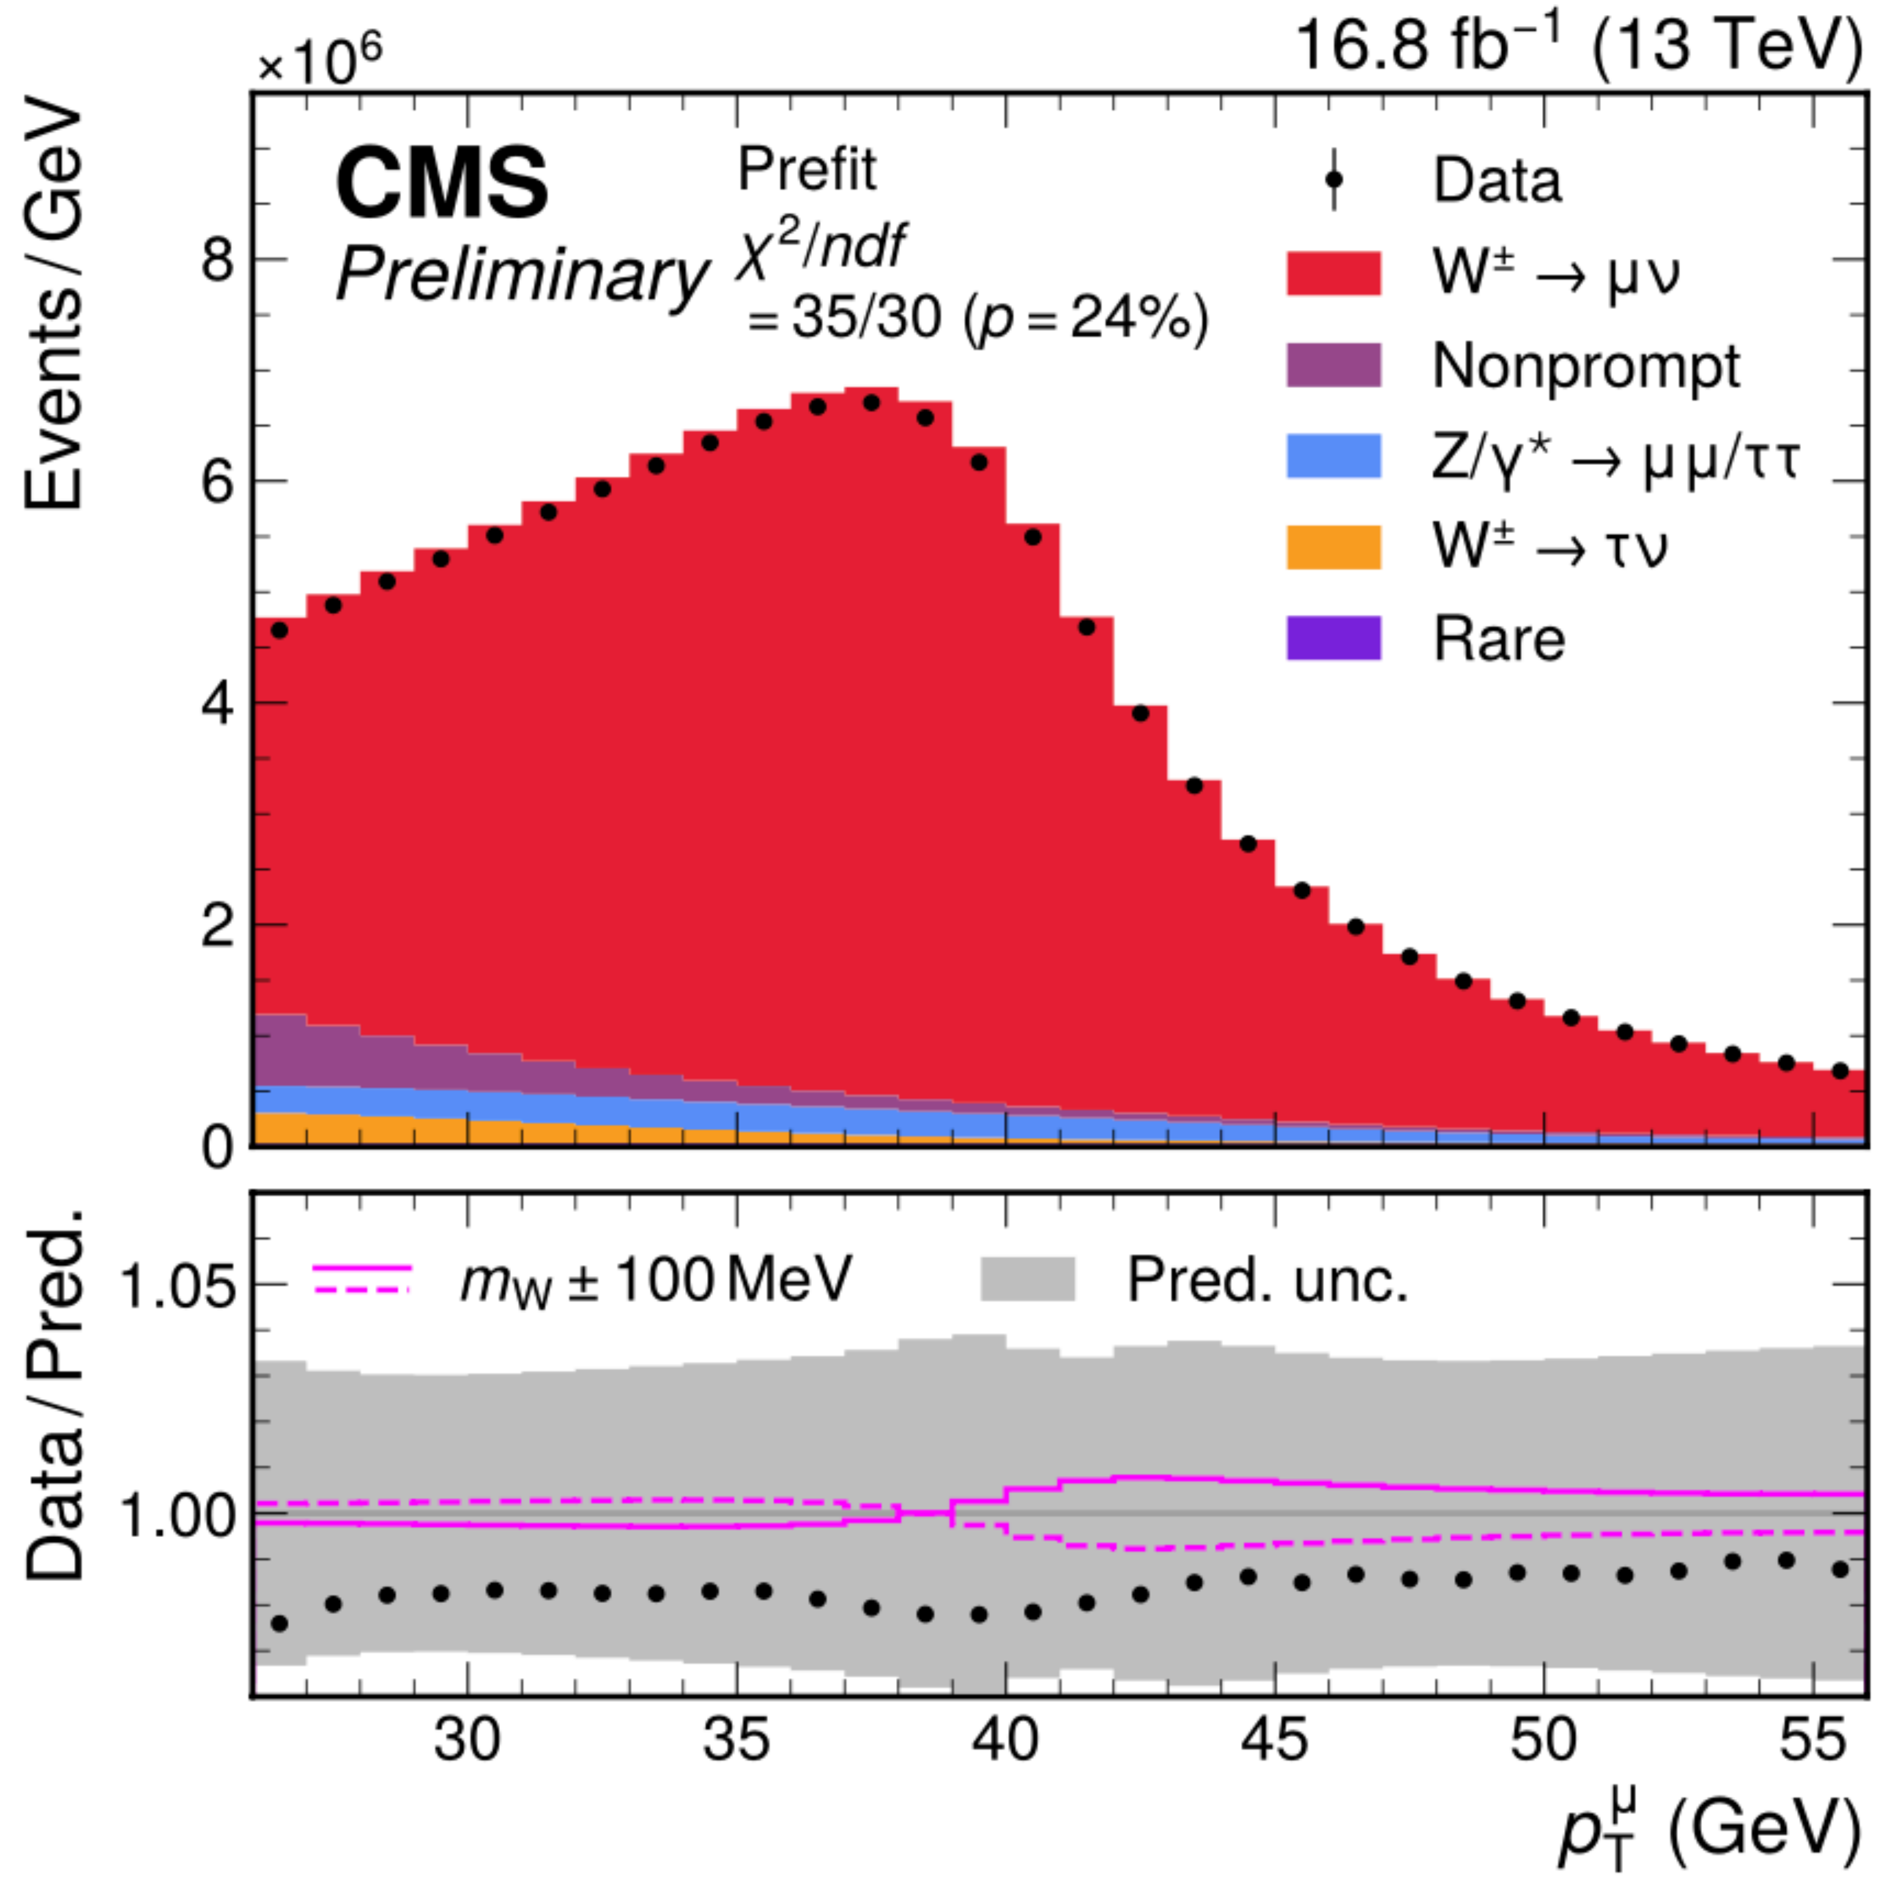
Statistical analysis

- Results from binned maximum likelihood fits to distributions sensitive to parameter-of-interest (m_W or m_Z)
  - **Using tensorflow-based** implementation of binned maximum likelihood fit
    - Avoid numerical instabilities due to fit complexities

- **O(3k) template bins in m_W fit and ~4000 nuisance parameters**

- **m_W (m_Z) uncertainty ± 100 MeV shift computed in simulation and propagated via event weights**
  - Unconstrained in fit
  - Extrapolation within range using log normal shape (validated to within < 0.1 MeV)
  - Consistent with typical χ^2 minimization

- **Measurement performed “blind”**
  - Likelihood fit with m_W only performed on data in final steps
  - m_Z and m_W values hidden, “unblinded” in sequence after finalising all inputs



Measurement sequencing and challenges

➡The m_W measurement is the culmination of an extensive program

★★★ Highly granular and precise estimation of μ reconstruction efficiency

★★★ Calibration of absolute p_T^μ scale ($\delta p_T^\ell \sim 10^{-4} \Longrightarrow \delta m_W \sim 8$ MeV)

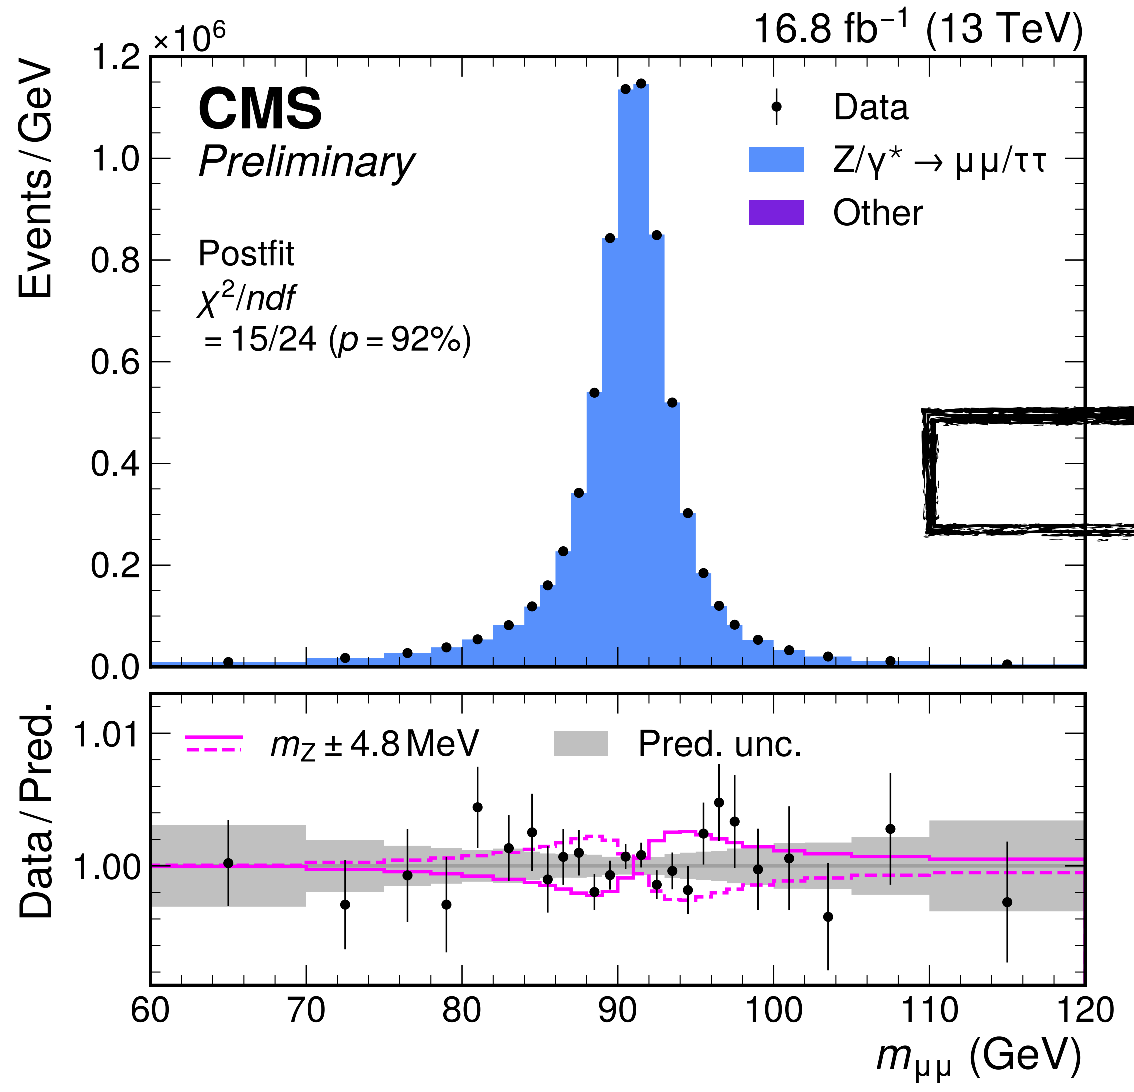
- ➡ > x10 better than typical CMS analysis

★★ Calibration of the W/Z boson hadronic recoil

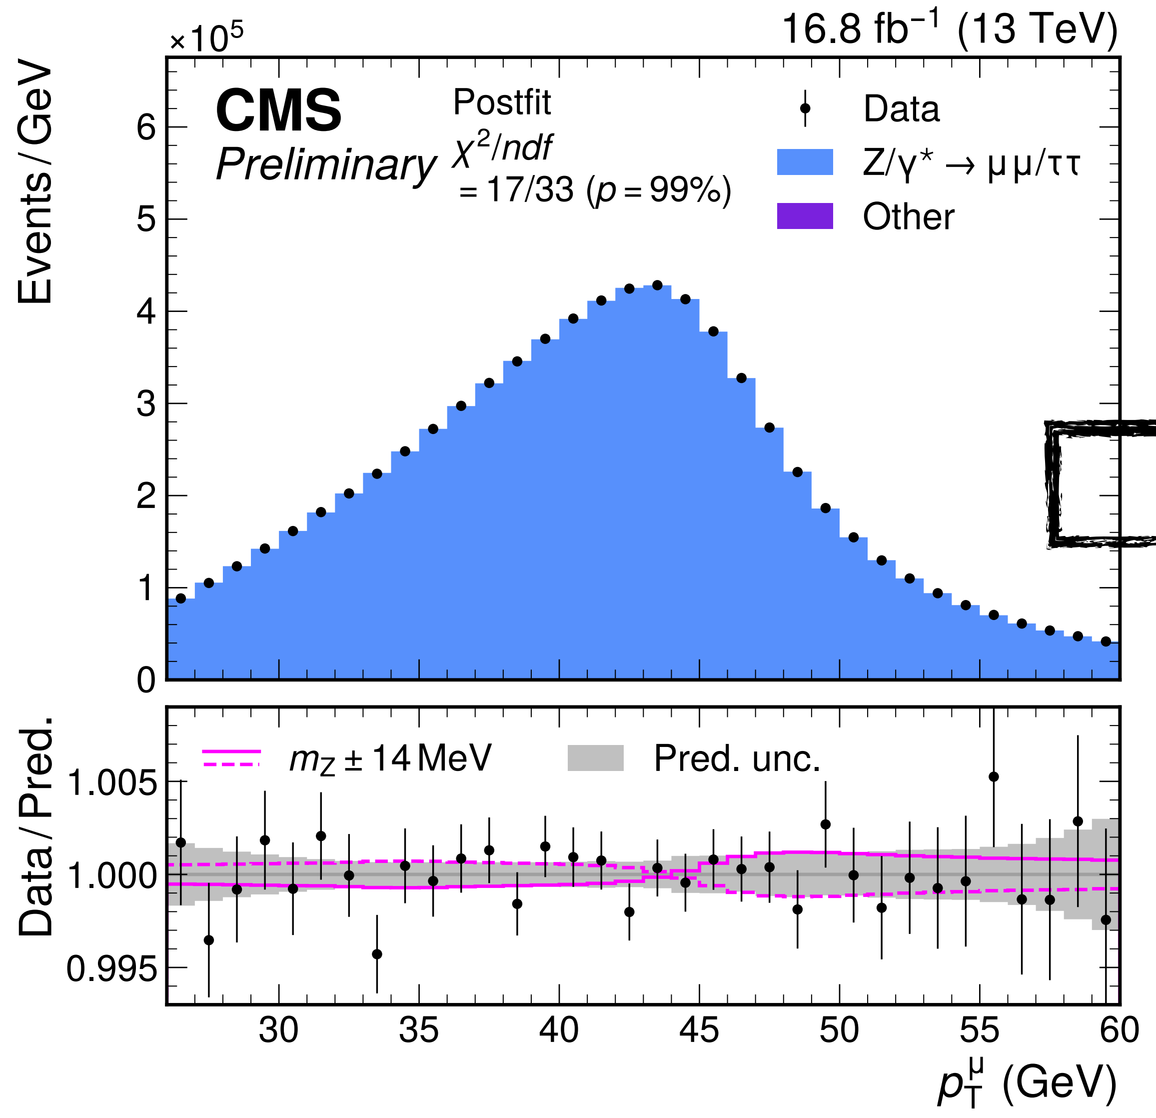
★★ Accurate modeling and uncertainty estimation for W/Z production

★ Estimation of backgrounds

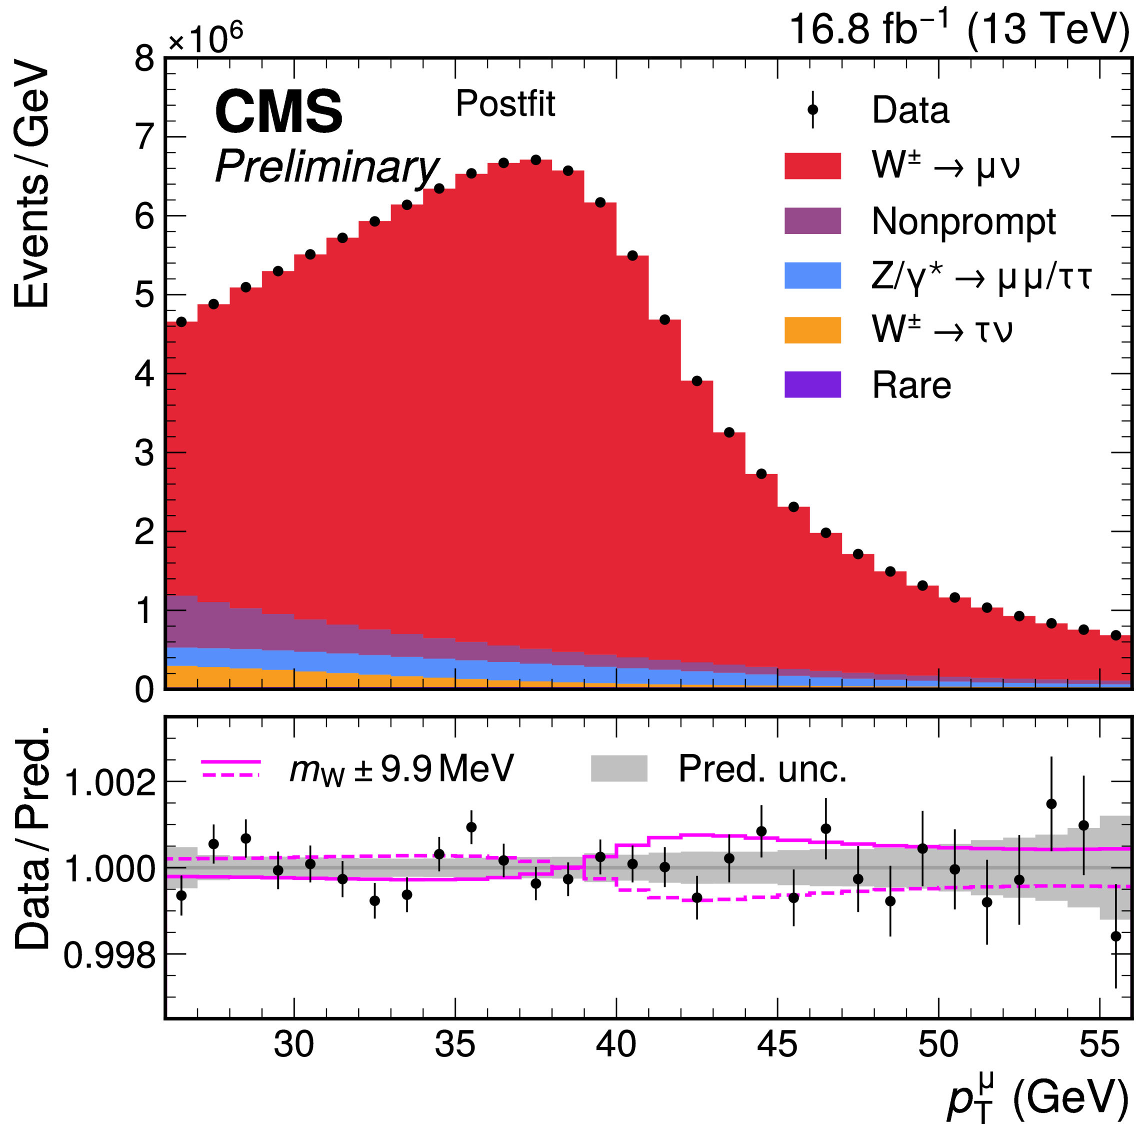
- primarily heavy flavour decays in jets mis-ID'd as leptons)



★ m_Z measurement from $m_{\mu\mu}$



★ m_Z measurement from p_T^μ



★ m_W measurement

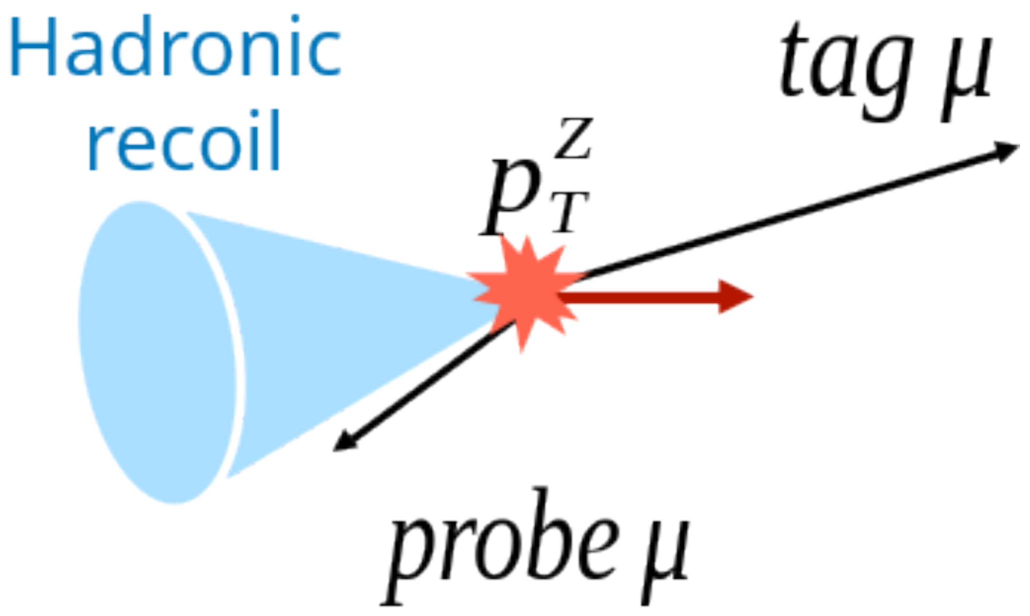
Muon reconstruction efficiency

- First step of analysis is reconstructing muons very precisely
  - *in situ* measurement of reconstruction rate from Z⟶μμ sample (tag-and-probe)
    - $\boldsymbol{\varepsilon}$ binned very finely in (p_T^μ ,η^μ) and divided by into steps:
      - tracking, track+muon system match, ID, trigger, isolation
    - Smoothed in p_T^μ to reduce stat. fluctuations
  - ~2400 nuisance parameters in final signal extraction

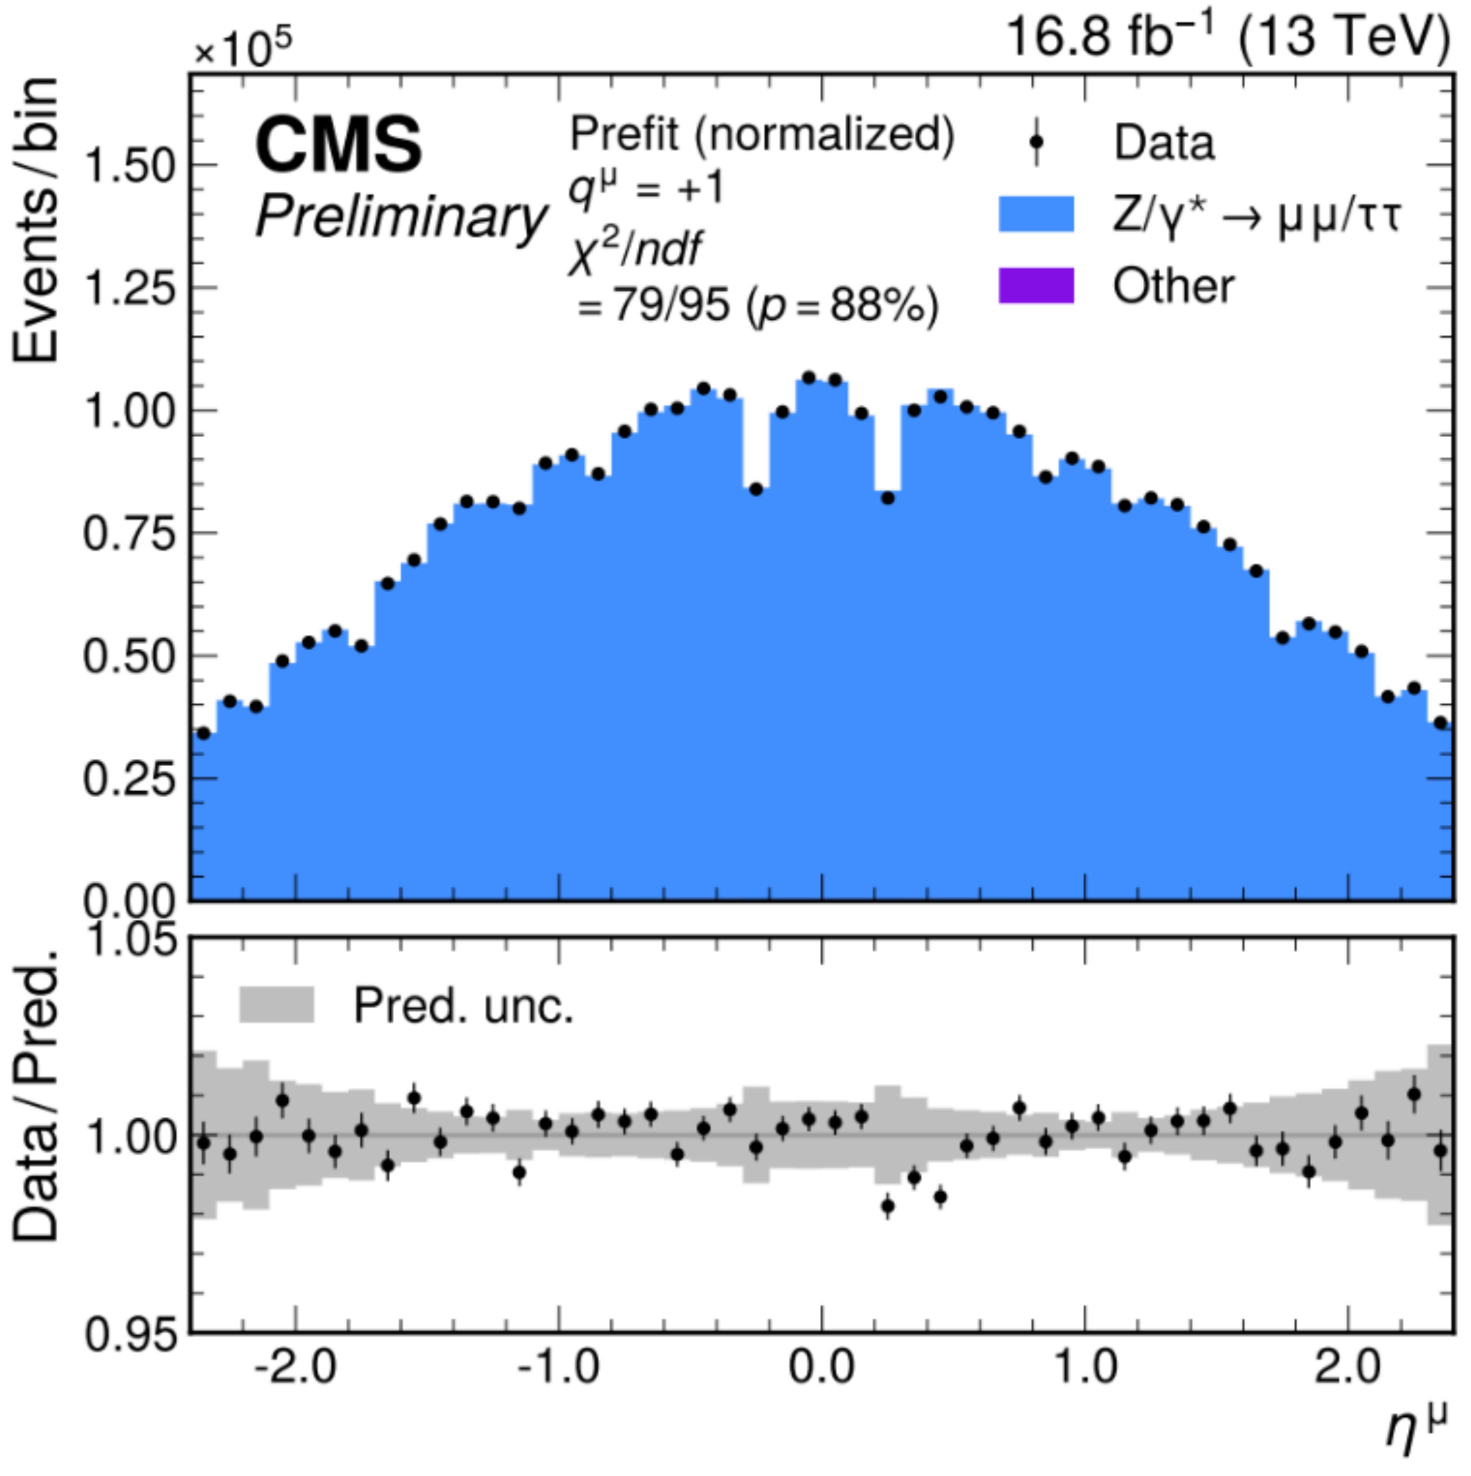
➡3.0 MeV unc. in m_W

$$\varepsilon = \frac{passing\ probes}{passing\ probes + failling\ probes}$$

- NB: for loss of events before the trigger, or differences between W and Z, this technique will fail to capture effects
  - Account for W/Z recoil differences
  - Vertexing selection modified for W/Z consistency
  - Trigger “pre-firing” estimated independently



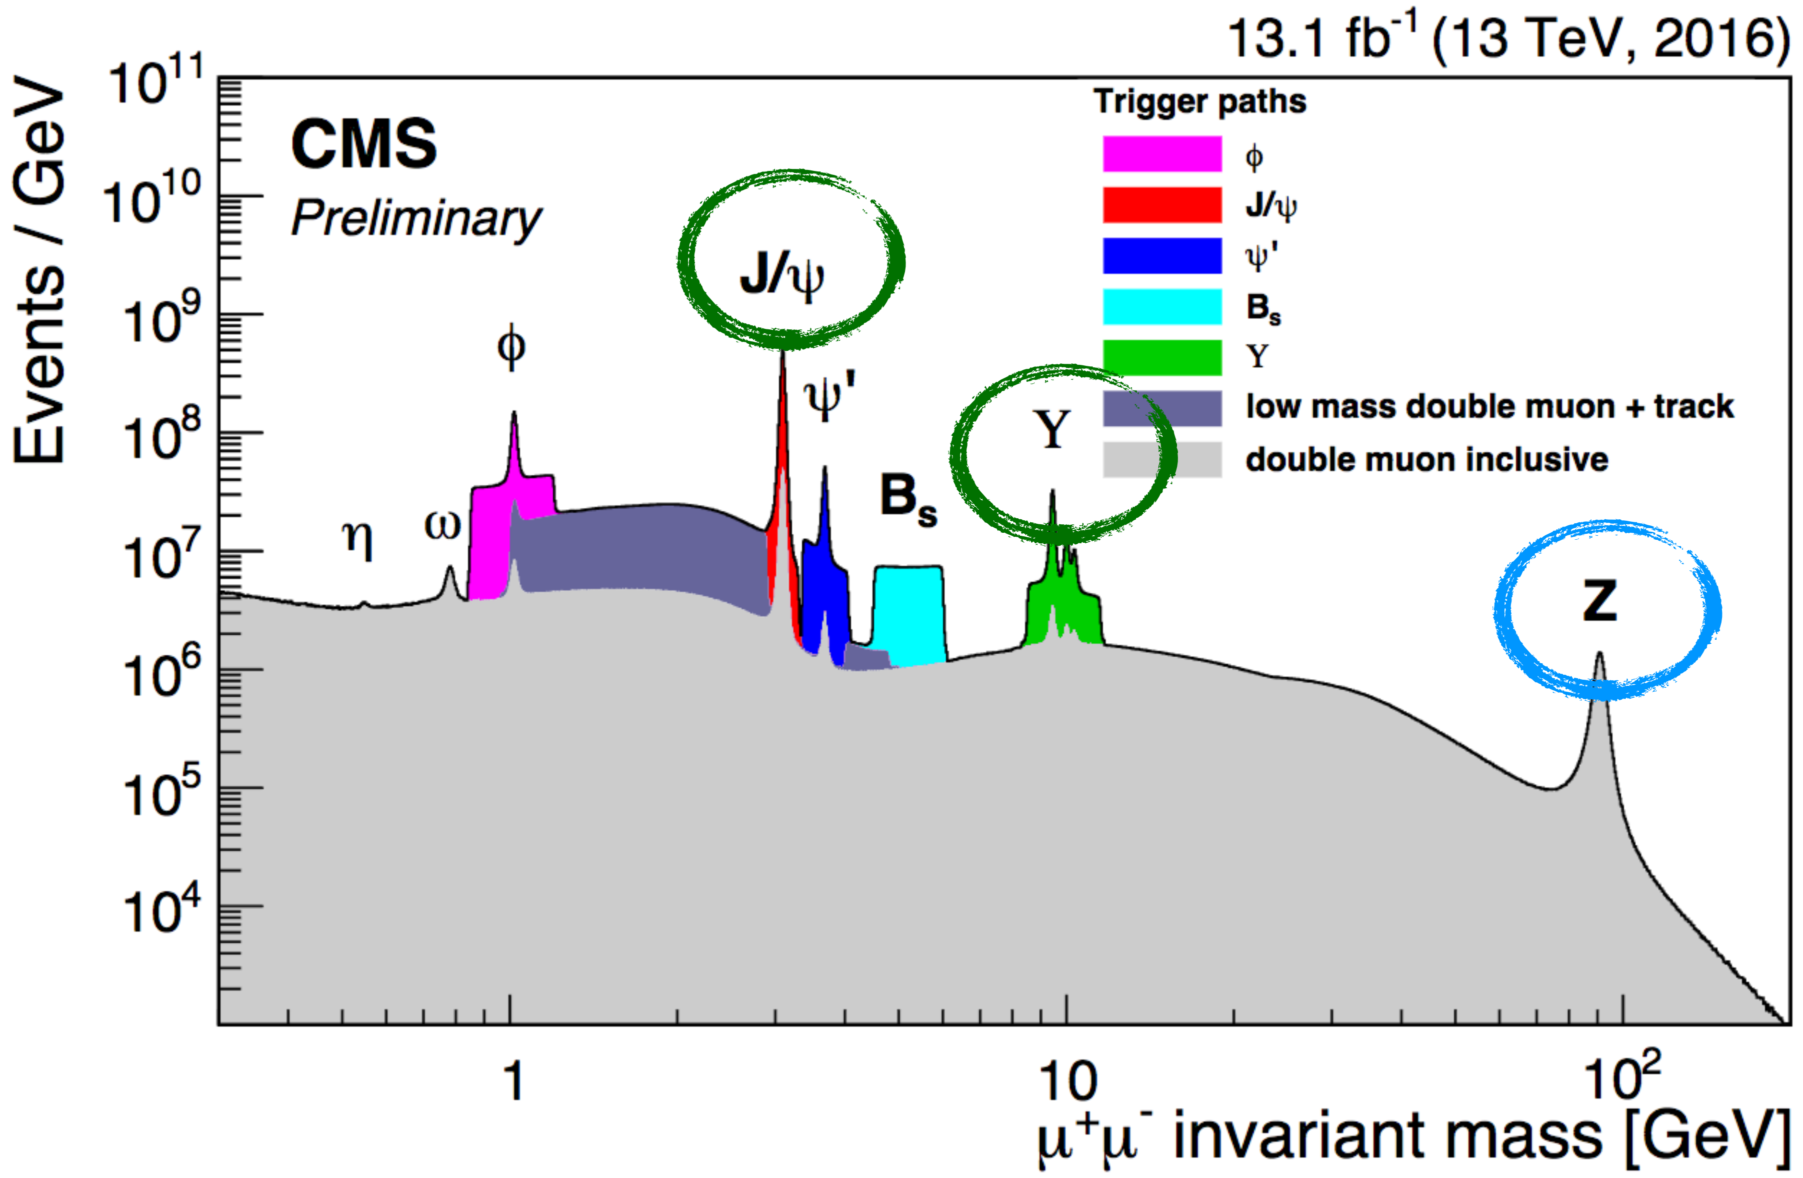
$$u_T = \frac{\vec{p}_T^{\,\mu} \cdot \vec{p}_T^{\,V}}{p_T^\mu}$$

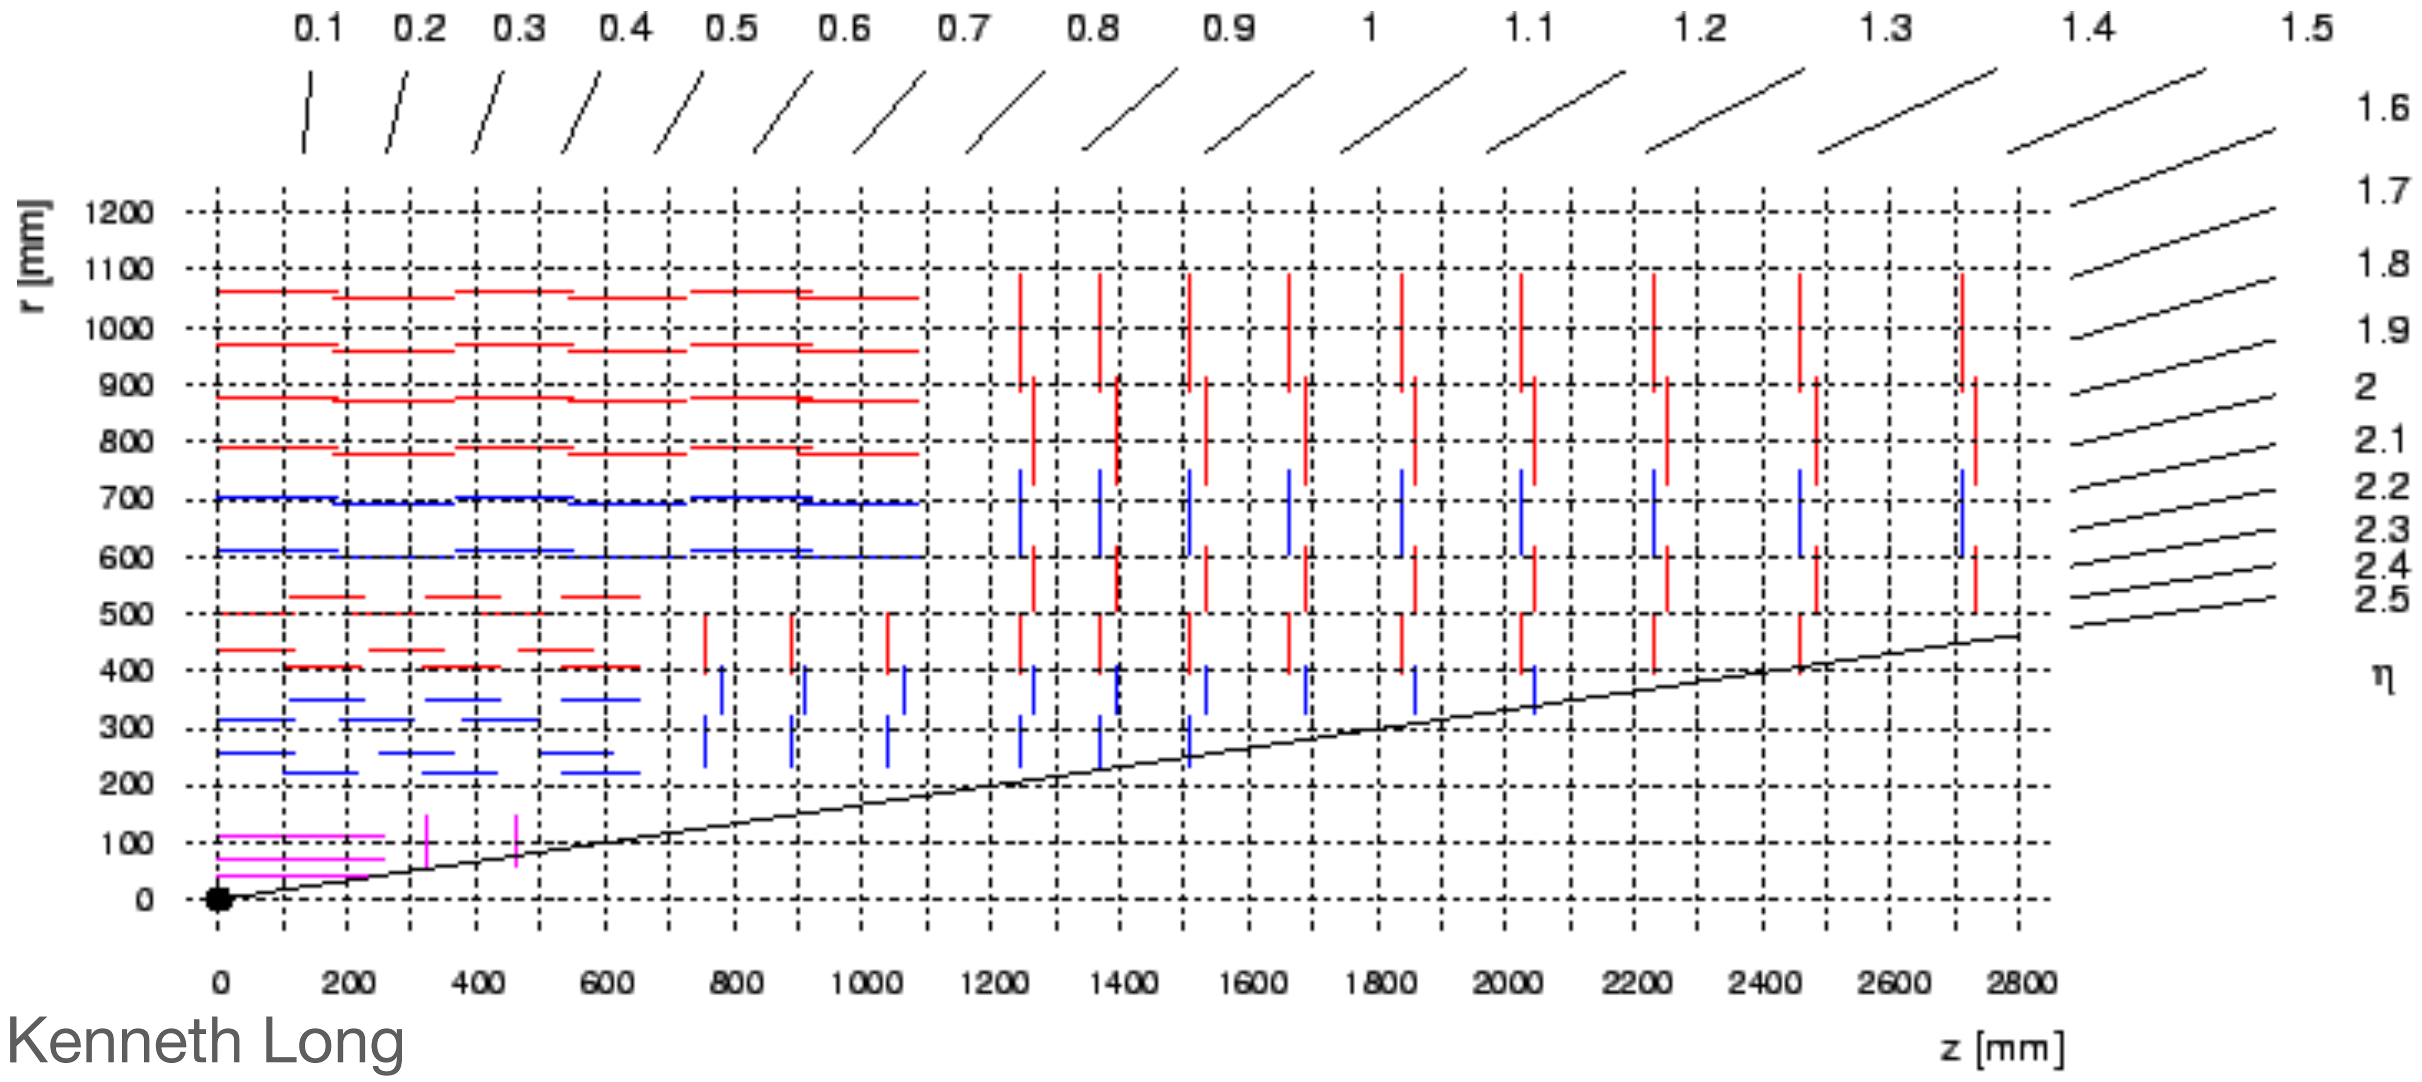


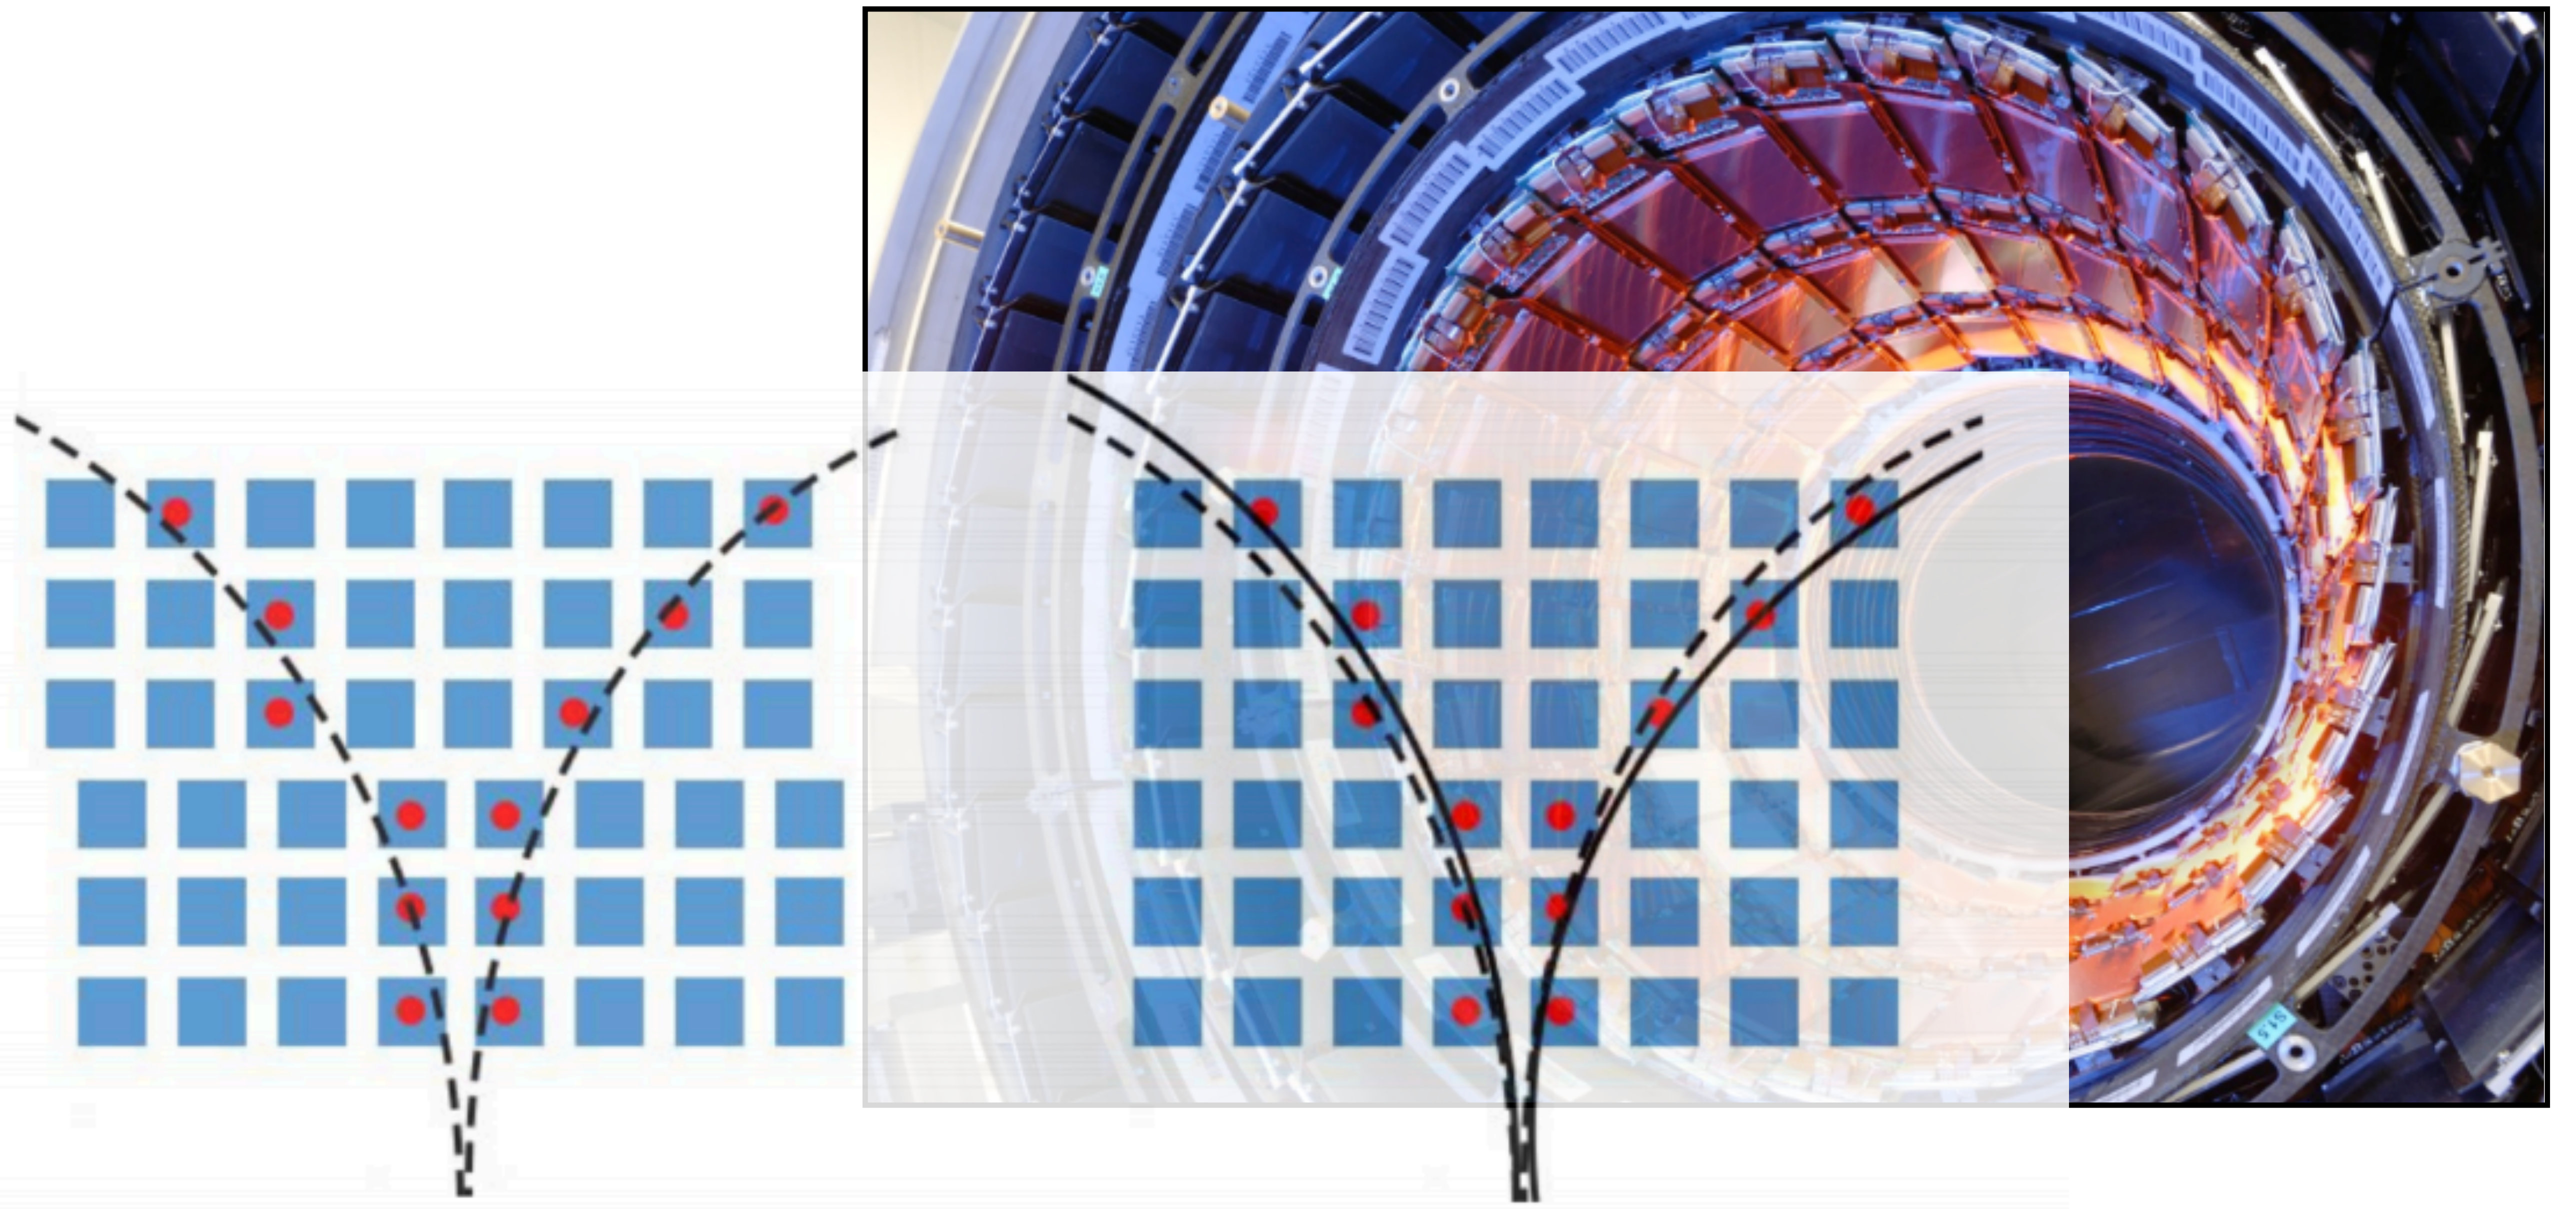
Muon momentum calibration: overview

- Momentum measured from track curvature
  - Up to ~17 hits per track: single-hit resolution of 9-50 μm
  - $\delta p_T^{\ell} \sim 10^{-4} \Longrightarrow$ Sagitta ~ 6 mm, $\delta S \sim 0.6$ μm
  - Significant material interactions
- **Absolute scale of curvature ⟺ momentum correspondence set by known resonance**
  - J/ψ or **ϒ** (use Z for validation)

  ➡Requires extrapolation across momentum range







If the tracker is misaligned and we don't know it...

...the track will be reconstructed as if the tracker was aligned

Muon momentum calibration: procedure

➡Need robust parameterisation extrapolation across p_T

- $k \equiv 1/p_T$ (curvature)
- A: magnetic field correction
- M: alignment correction
- e: energy loss correction (e.g., material budget)

$$k_{corr} = Ak + qM + \frac{k}{1+ek}$$

$$\boxed{\delta k/k \approx A + qM/k - ek}$$

- Multi-step procedure
  - Improved, custom refit of track to muon hits to remove bias
  - Apply module-by-module corrections obtained from track refit
  - Derive parameterised corrections (binned in η^{μ}) from fit to J/ψ resonance

  ➡Validate J/ψ-based calibration with Υ(1S) and Z

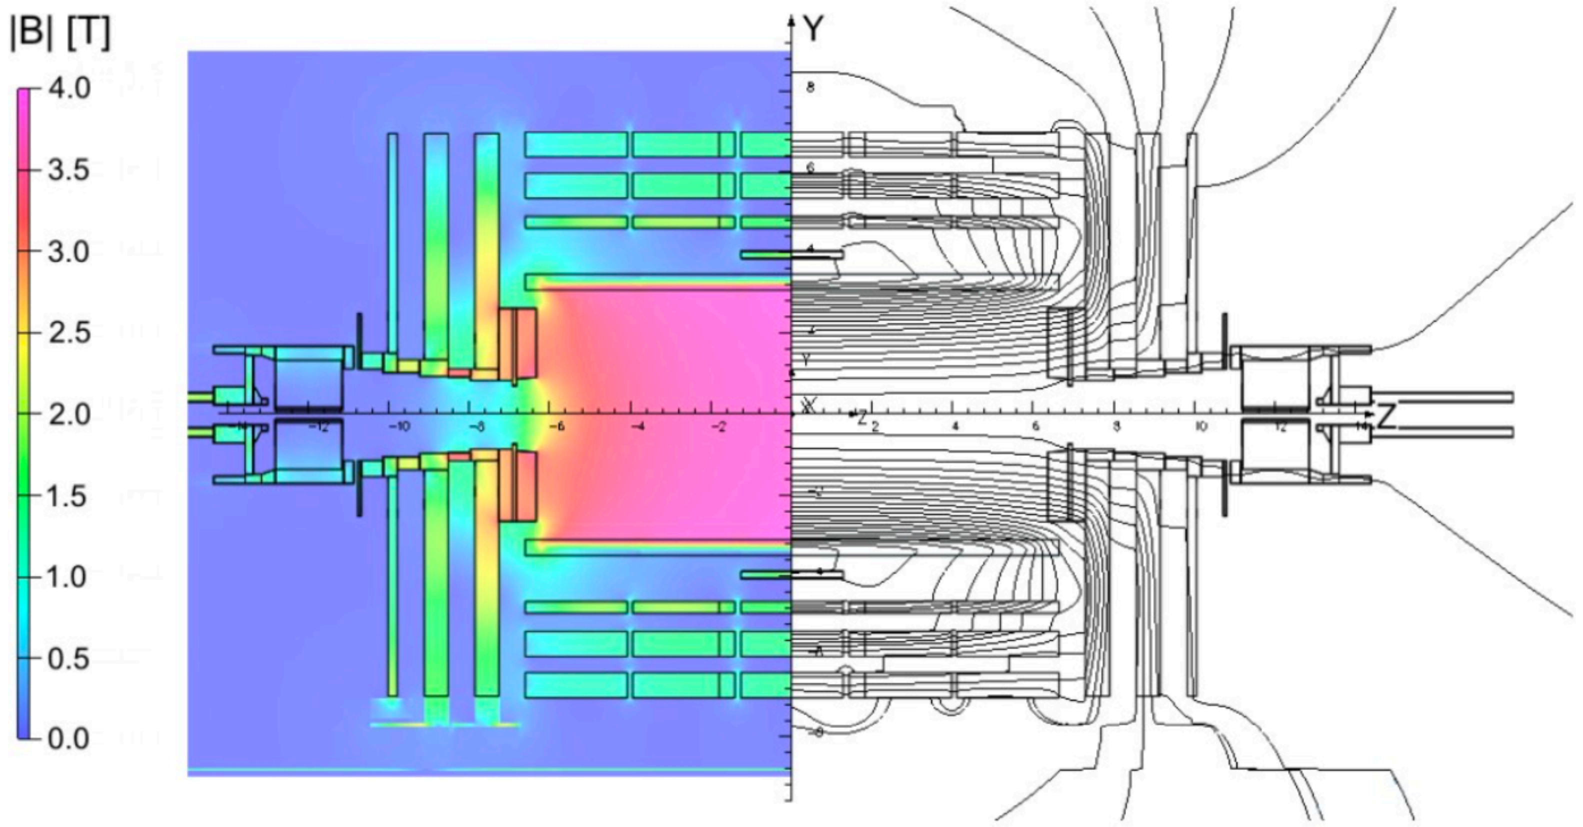
- Corrections for muon momentum resolution derived from binned (in η^{μ}) fits to Z events
  - Parameterised to account for multiple scattering (a), hit resolution (c), and correlation terms (b,d)

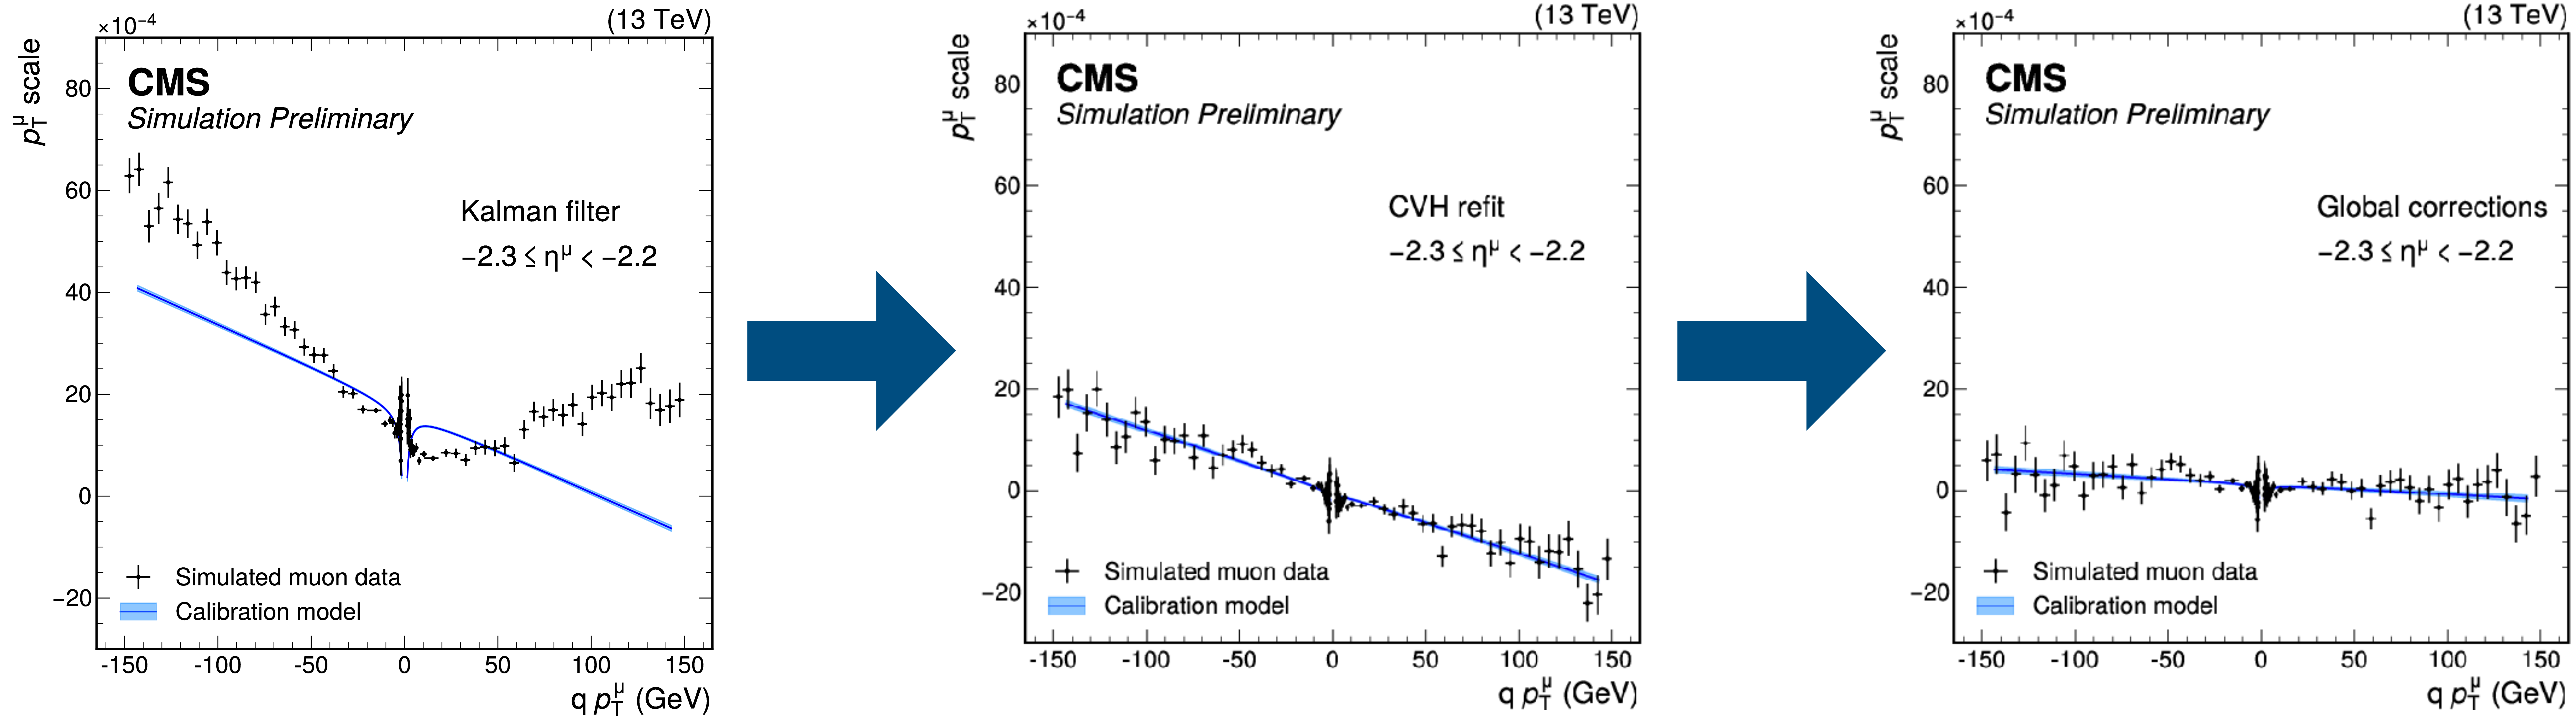
$$\left(\frac{\sigma_{p_T}}{p_T}\right)^2 = a^2 + c^2 \cdot p_T^2 + \frac{b^2}{1+\frac{d^2}{p_T^2}}$$

Muon momentum scale calibration: custom track fit

- **Refit muon hits using custom “Continuous Variable Helix” fit**
- **Model material in helix fit with Geant4**+additional params for B-field
  - Increase Geant precision wrt standard CMS reco.
- **Use of high-precision B-field map** (lower speed wrt standard reco.)

➡Extract and apply per-module parameter corrections





Default CMS reco.

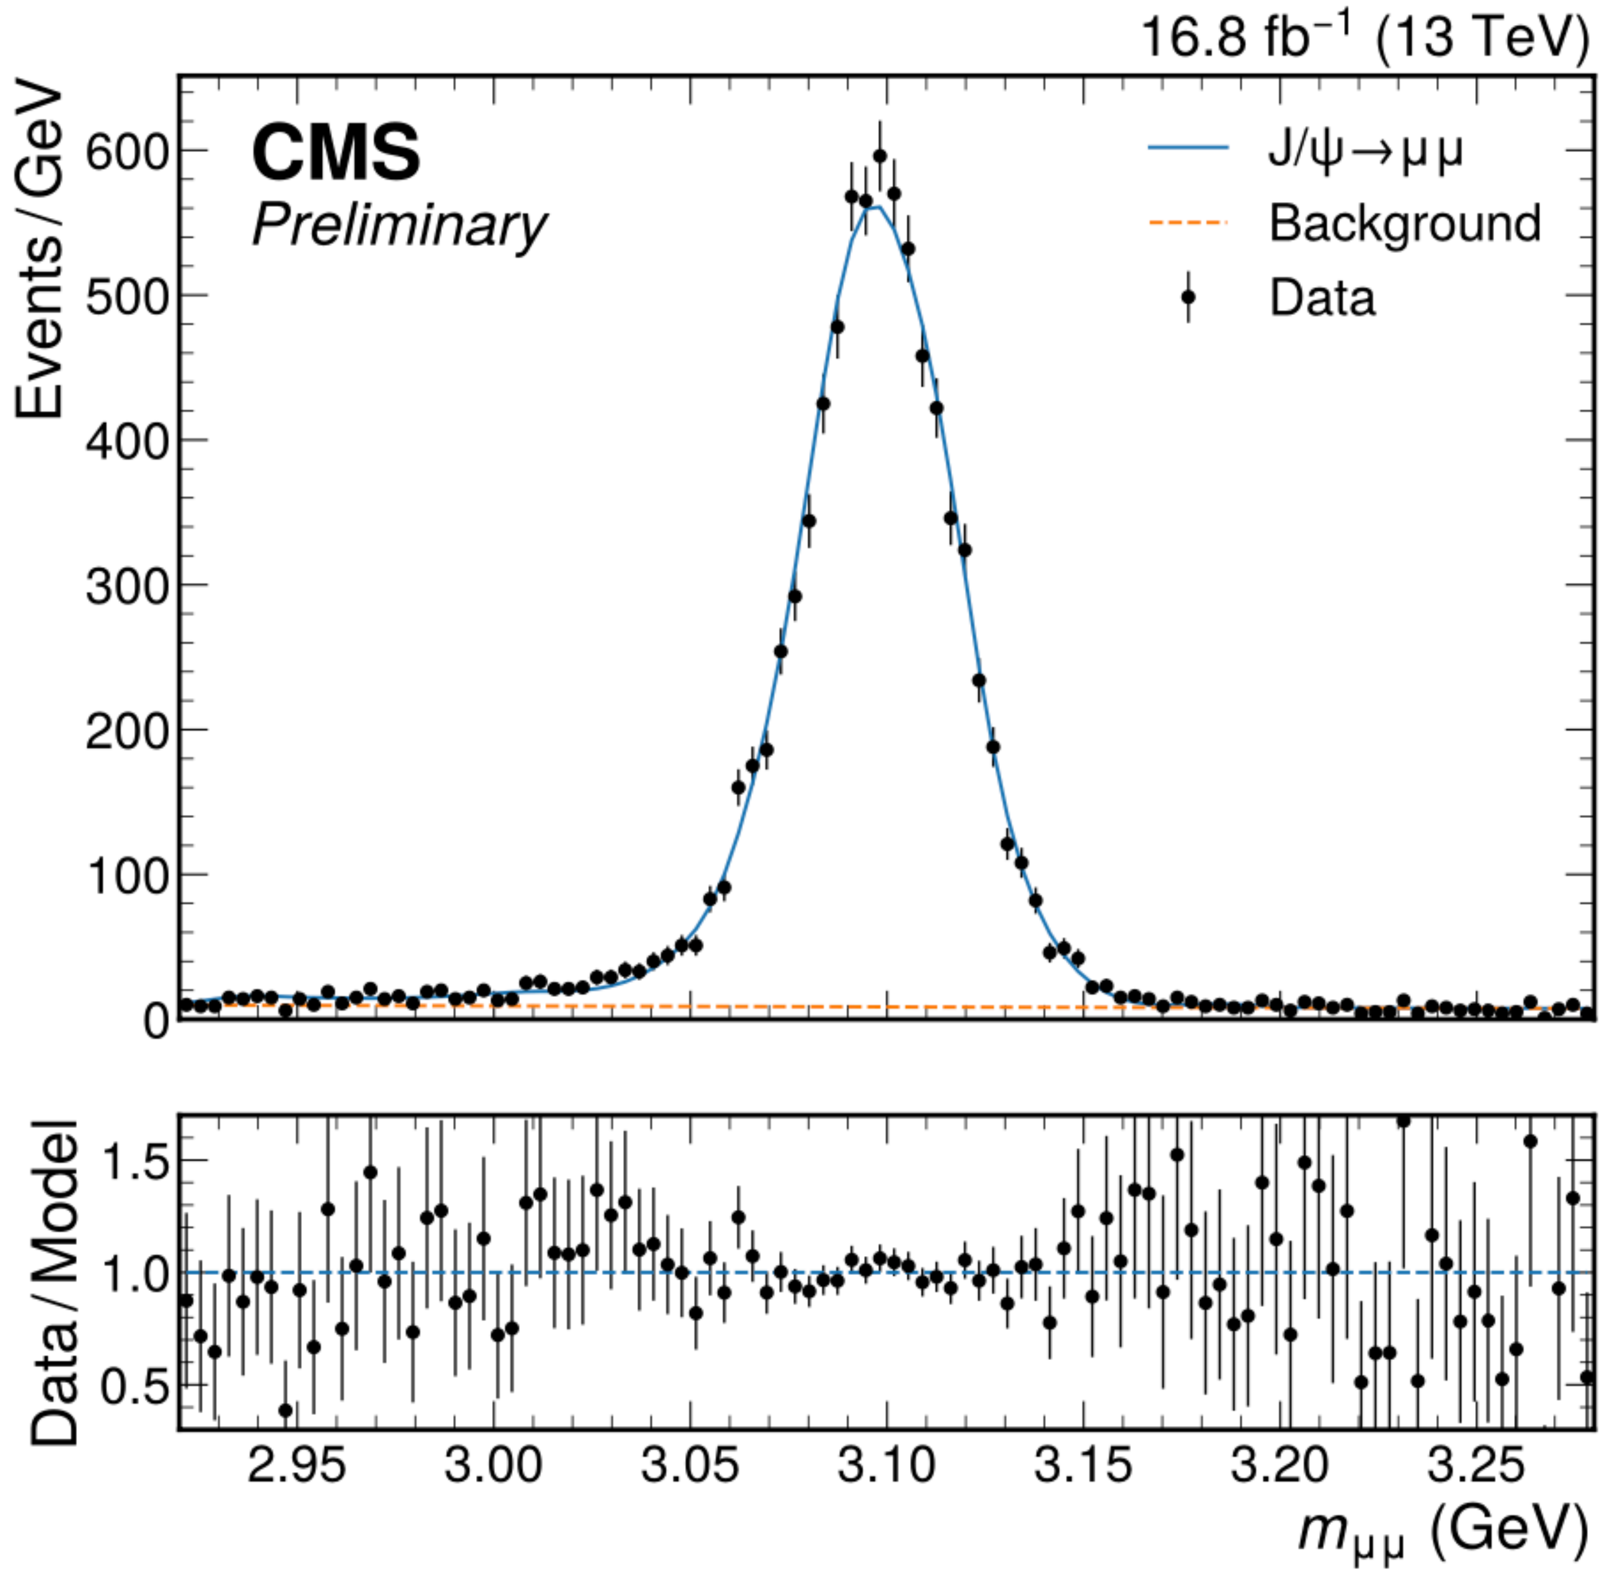
CVH refit

CVH refit+corr.

Fit of parameterisation function to single muon simulation vs. ground truth

Physics-model corrections from resonant mass fits

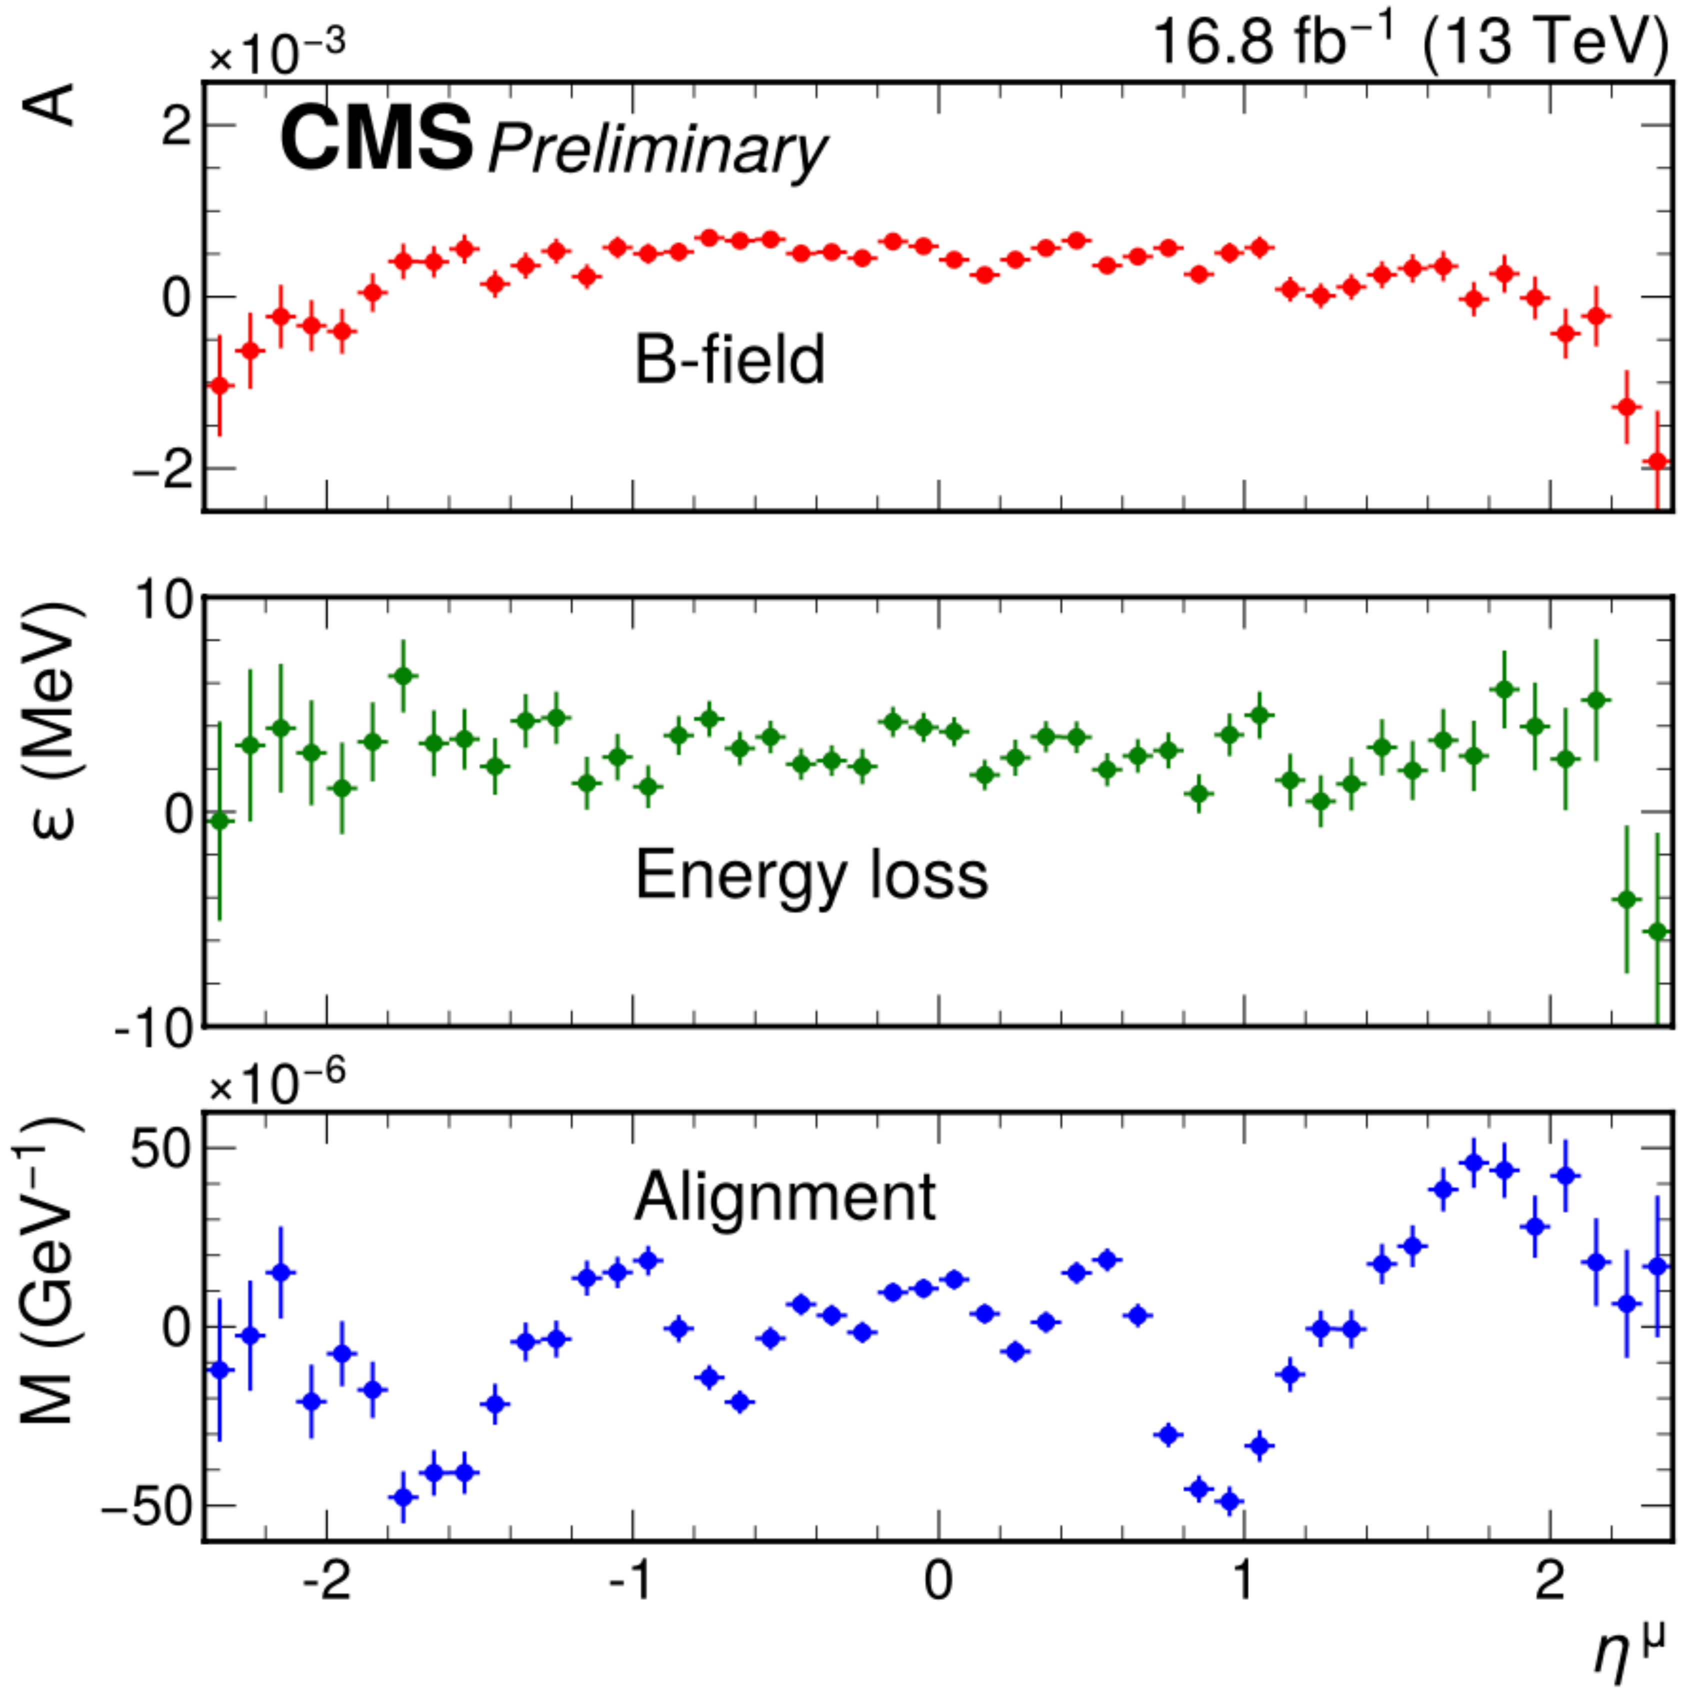
- Parameter extraction procedure
  1. **Fit J/ψ mass** in a binned 4D space of ($p_T^{\mu+}$, $p_T^{\mu-}$, $\eta^{\mu+}$, $\eta^{\mu-}$)
  2. Using χ^2 minimization, **extract η-binned calibration parameters** per muon
  3. Closure test: **perform same procedure on Υ(1S) and Z to assess consistency**



$$\boxed{\delta k/k \approx A + qM/k - ek}$$

Left: example fit to J/ψ in central η bin

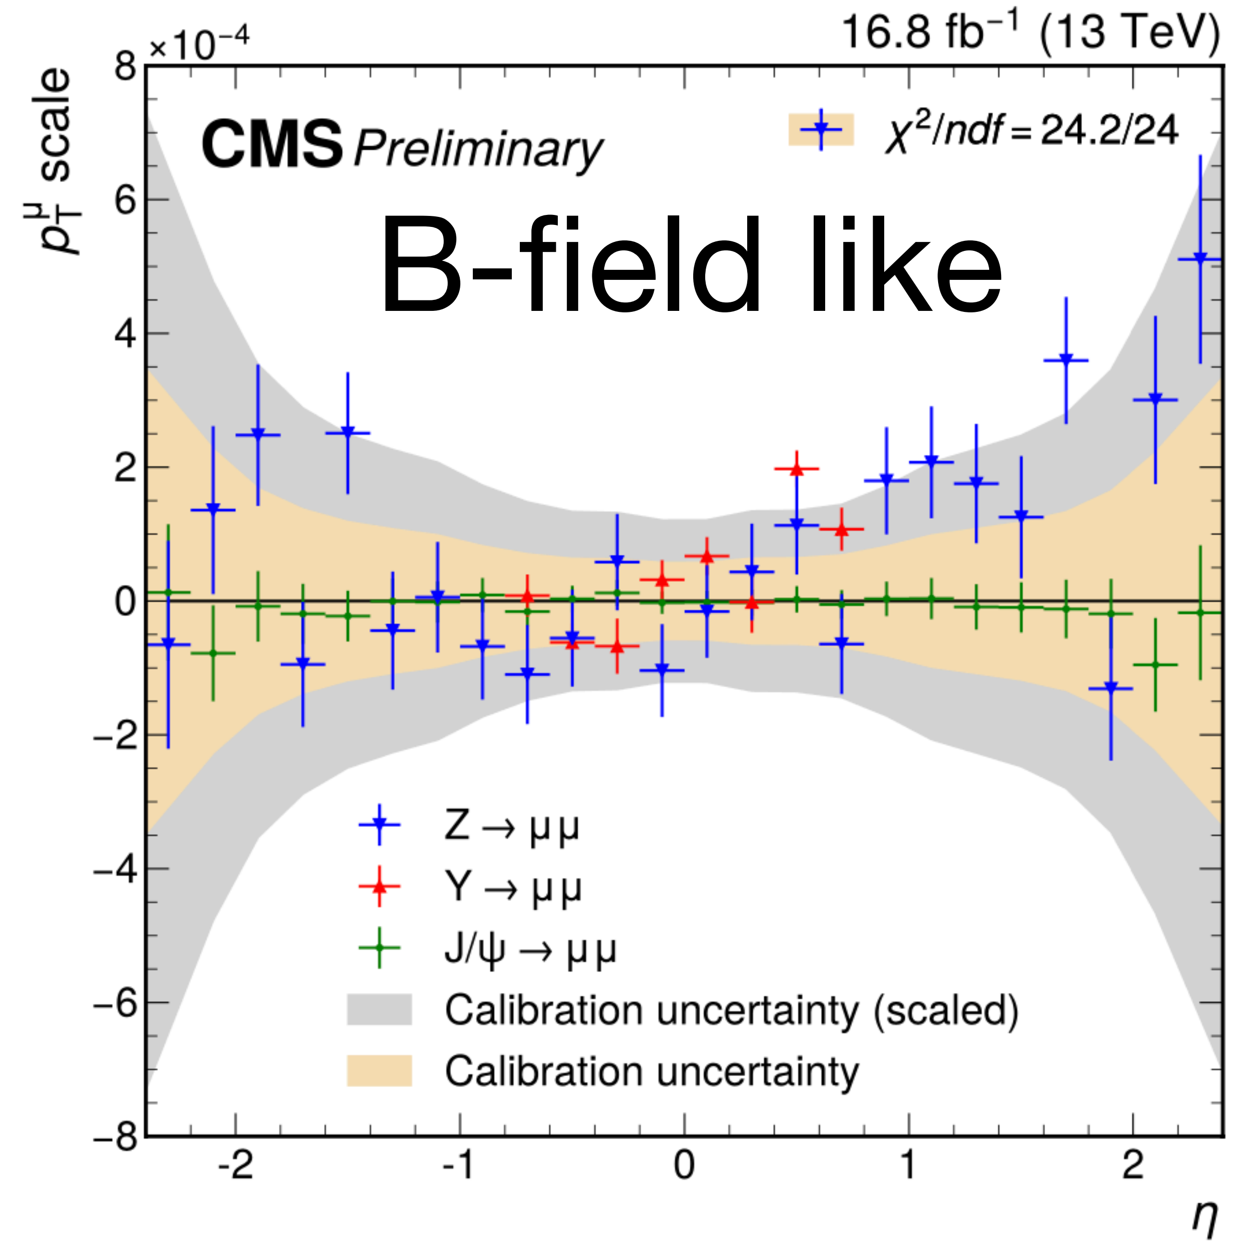
Right: Extracted parameters per η bin, (on top of module-level corrs.)

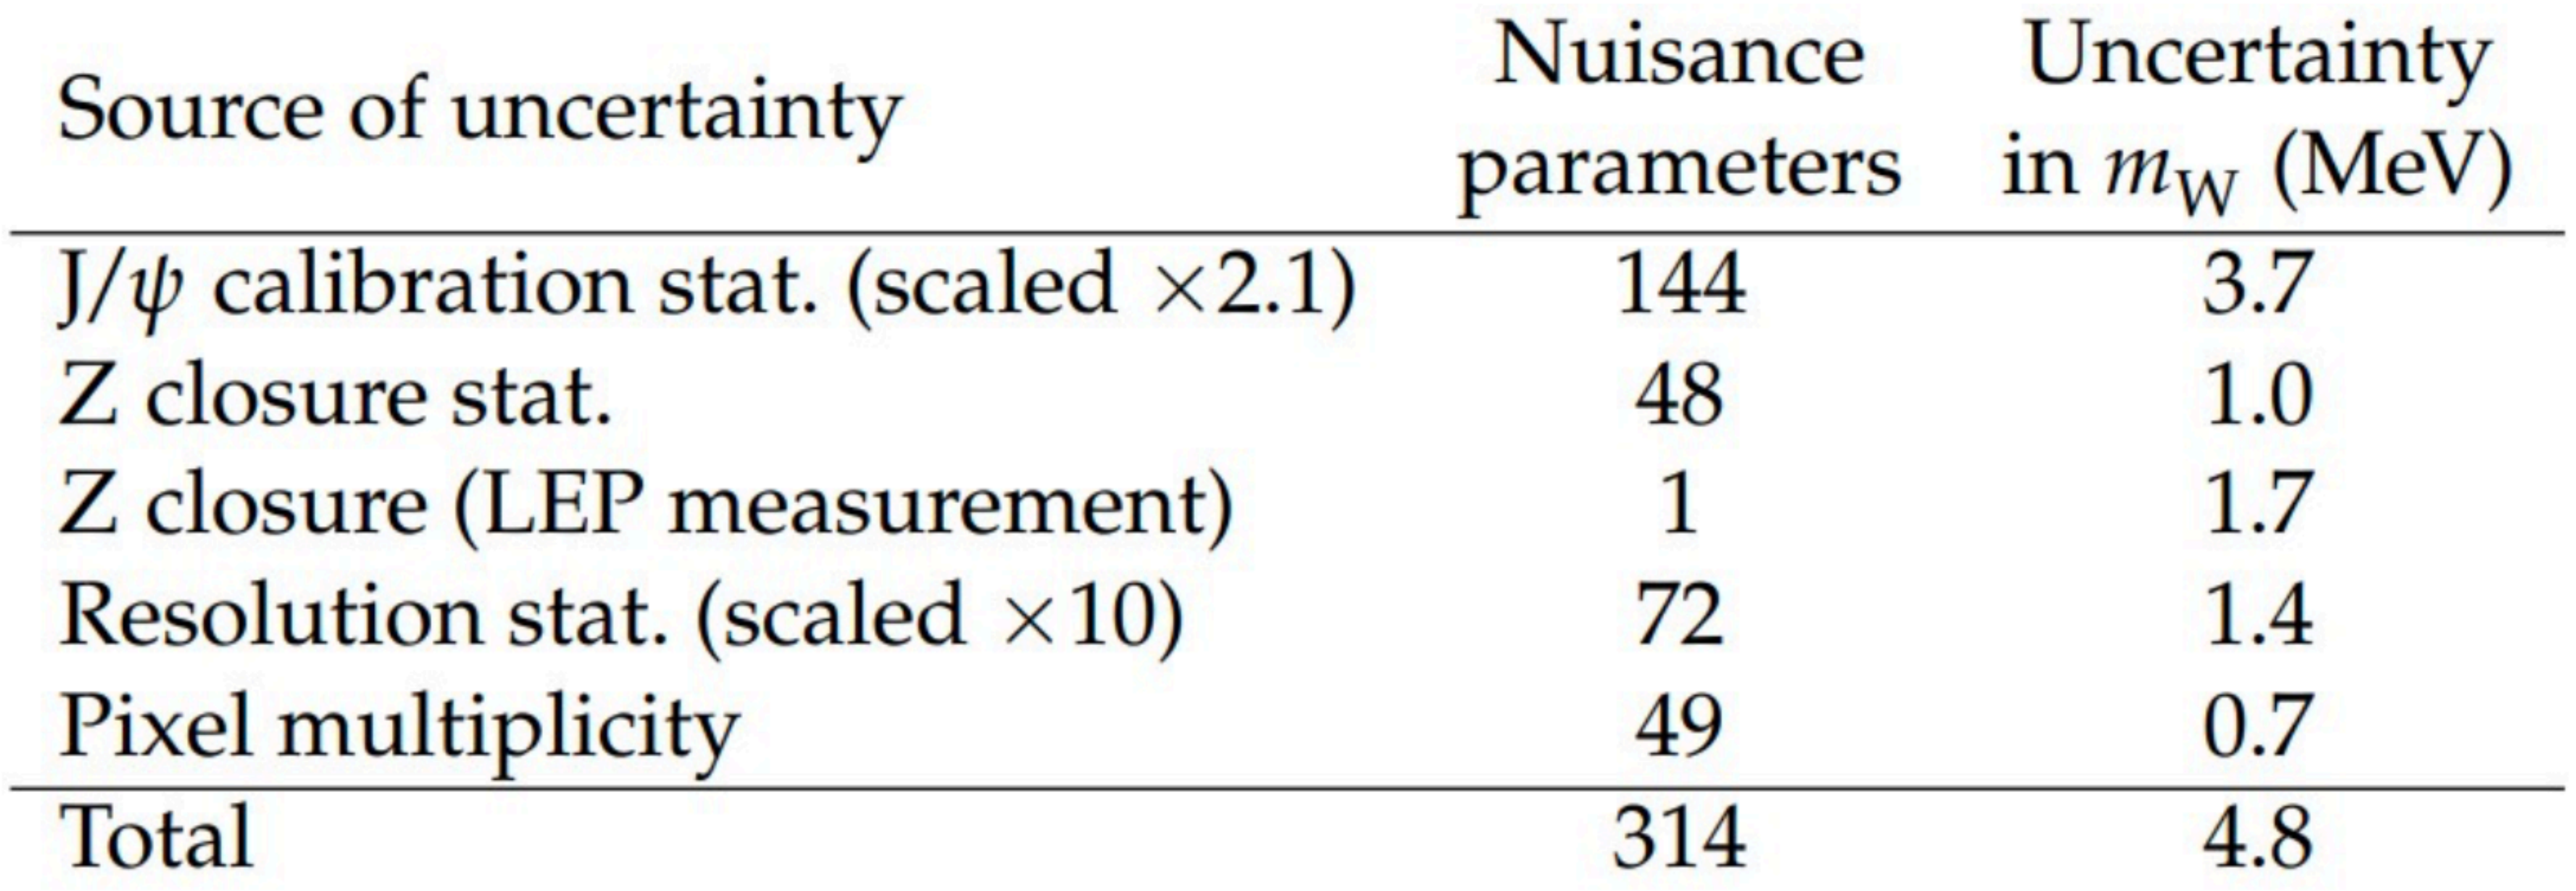


Calibration uncertainty and consistency between J/ψ, Υ, and Z

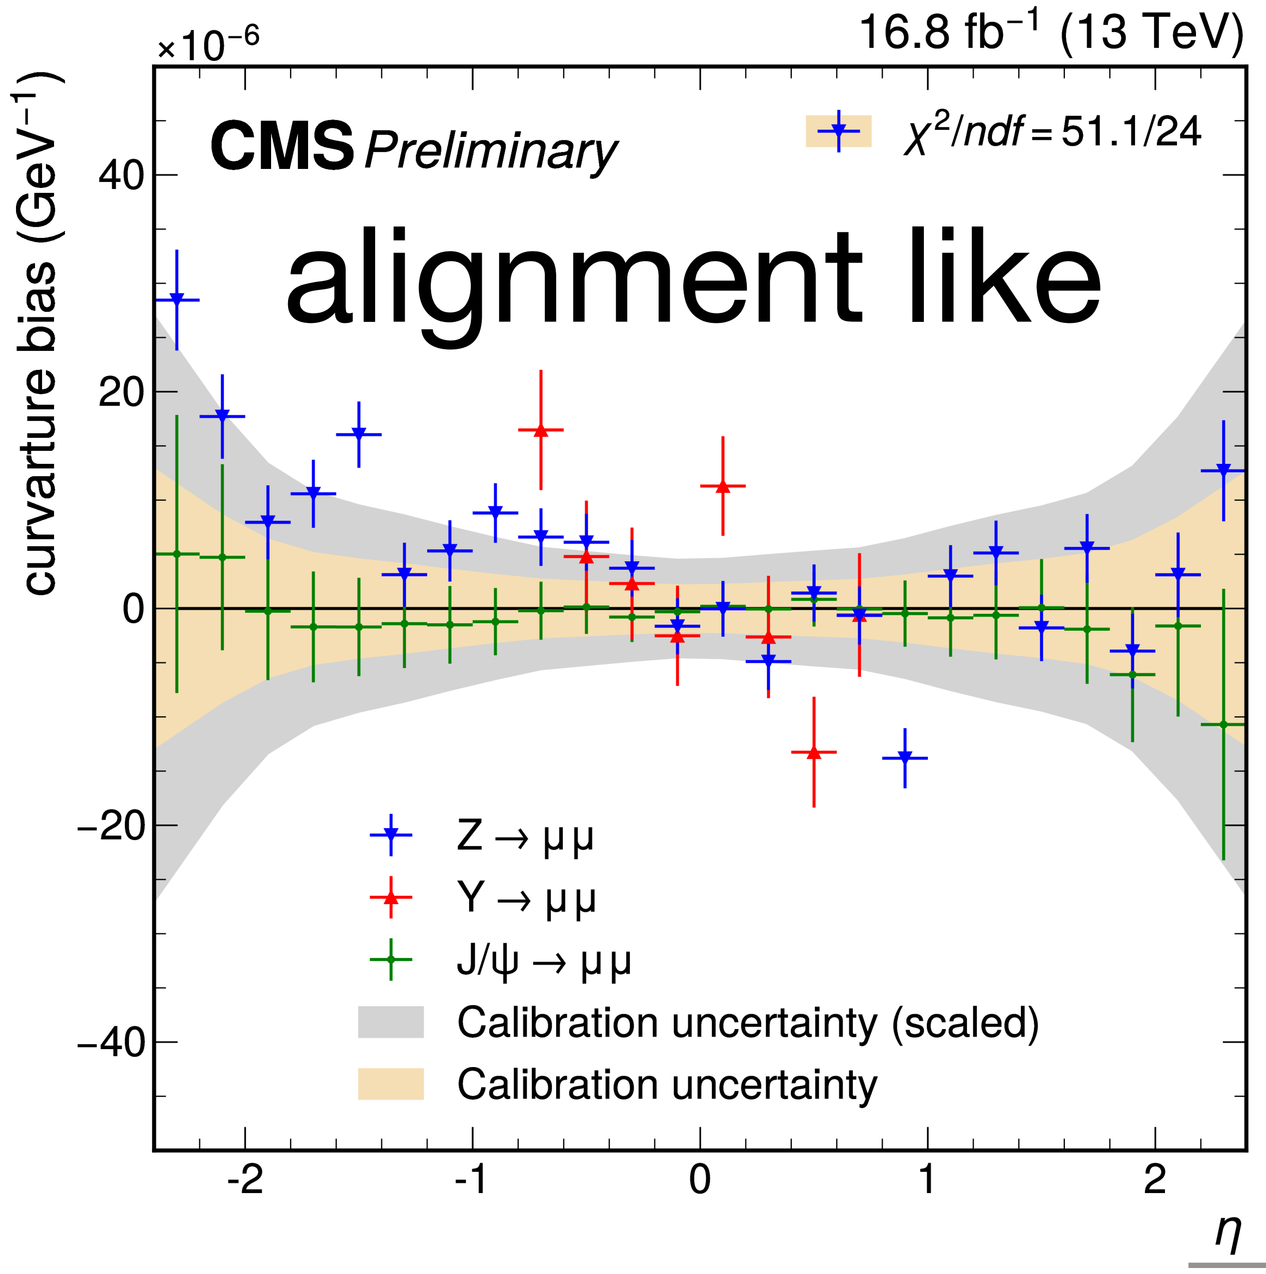
- Closure tests: apply mass-fit procedure to Υ(1S) and Z
    1. Correct by binned (A, e, M) parameters from J/ψ
    2. Fit for residual correction to parameters
- Stat. unc. in parameters from J/ψ used as basis for systematic unc.
    - Scaled up by 2.1 for full coverage
    - Confirmed impact in analysis is within unc.

➡Uncertainty in m_W 4.8 MeV





Source of uncertainty	Nuisance parameters	Uncertainty in m_W (MeV)
J/ψ calibration stat. (scaled ×2.1)	144	3.7
Z closure stat.	48	1.0
Z closure (LEP measurement)	1	1.7
Resolution stat. (scaled ×10)	72	1.4
Pixel multiplicity	49	0.7
Total	314	4.8



ATLAS: calibration on Z (~7 MeV unc.)

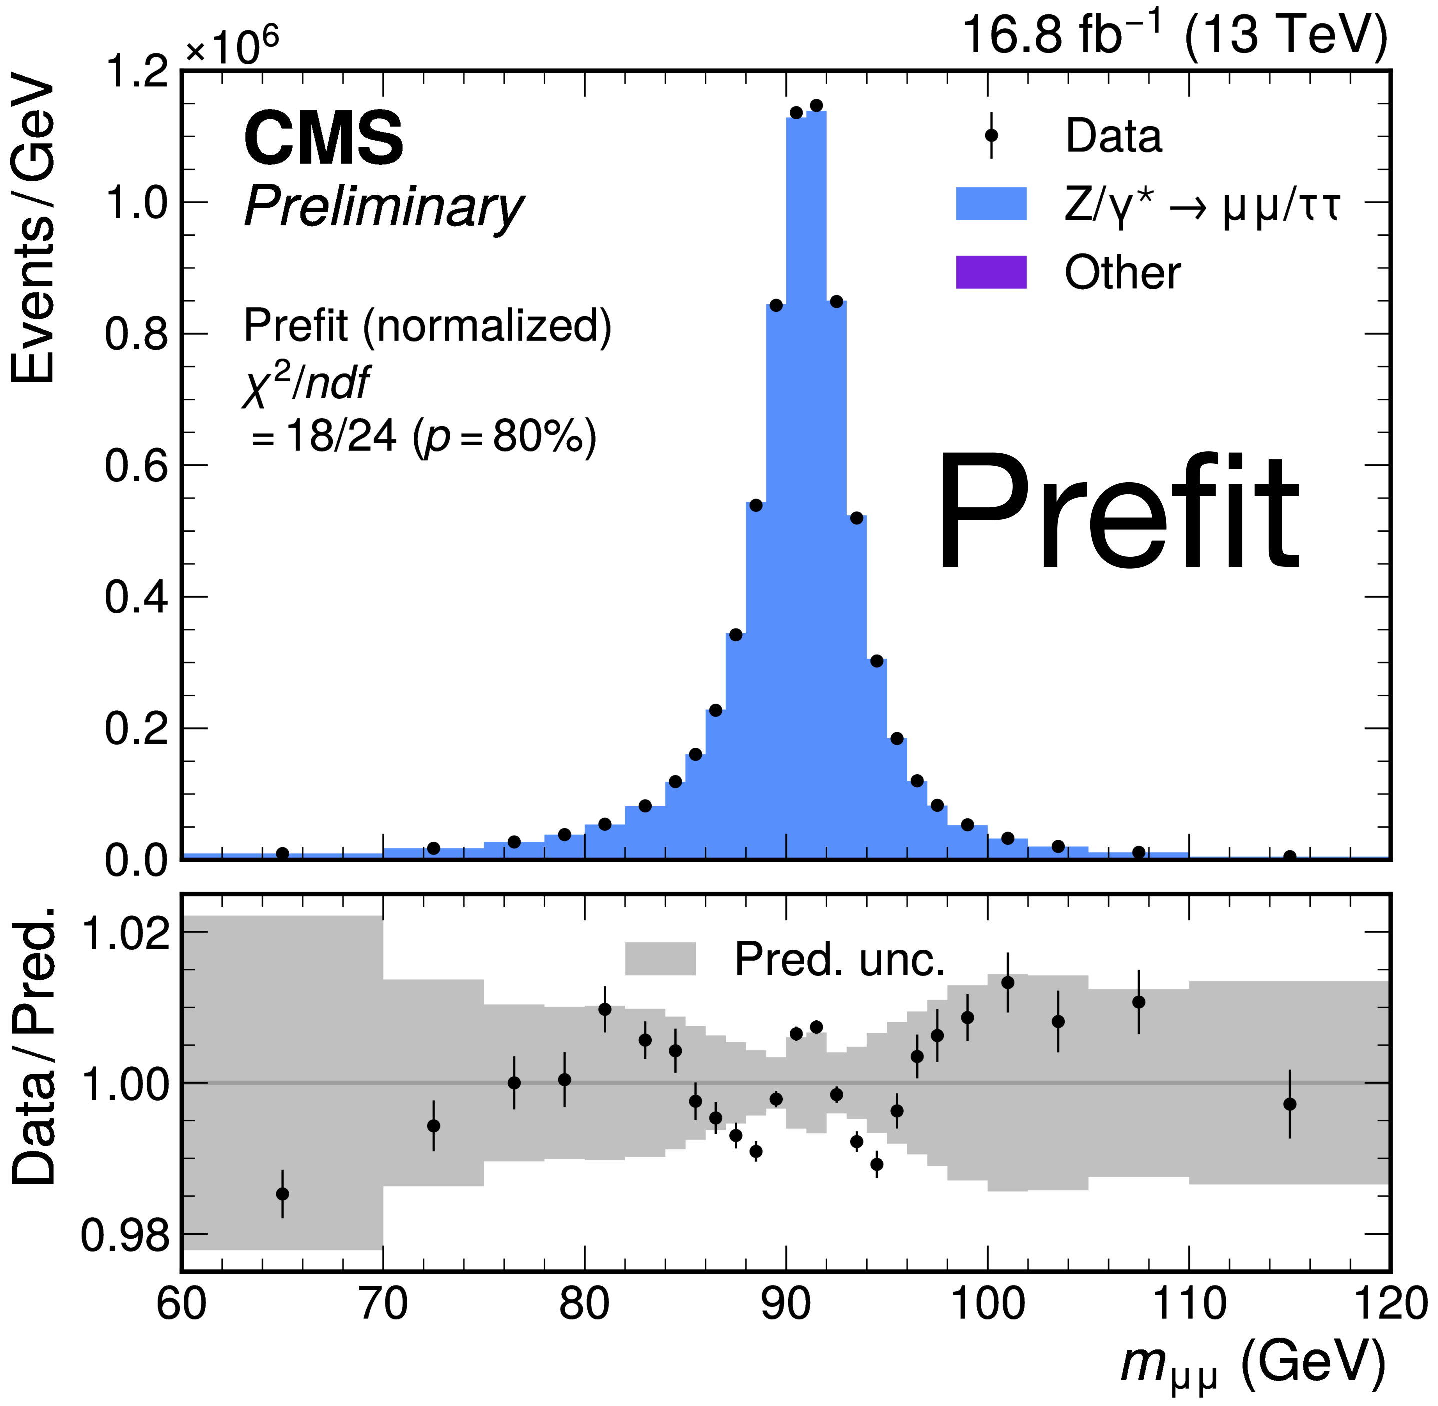
CDF: Combination of J/ψ, ϒ, and Z (3 MeV unc.)

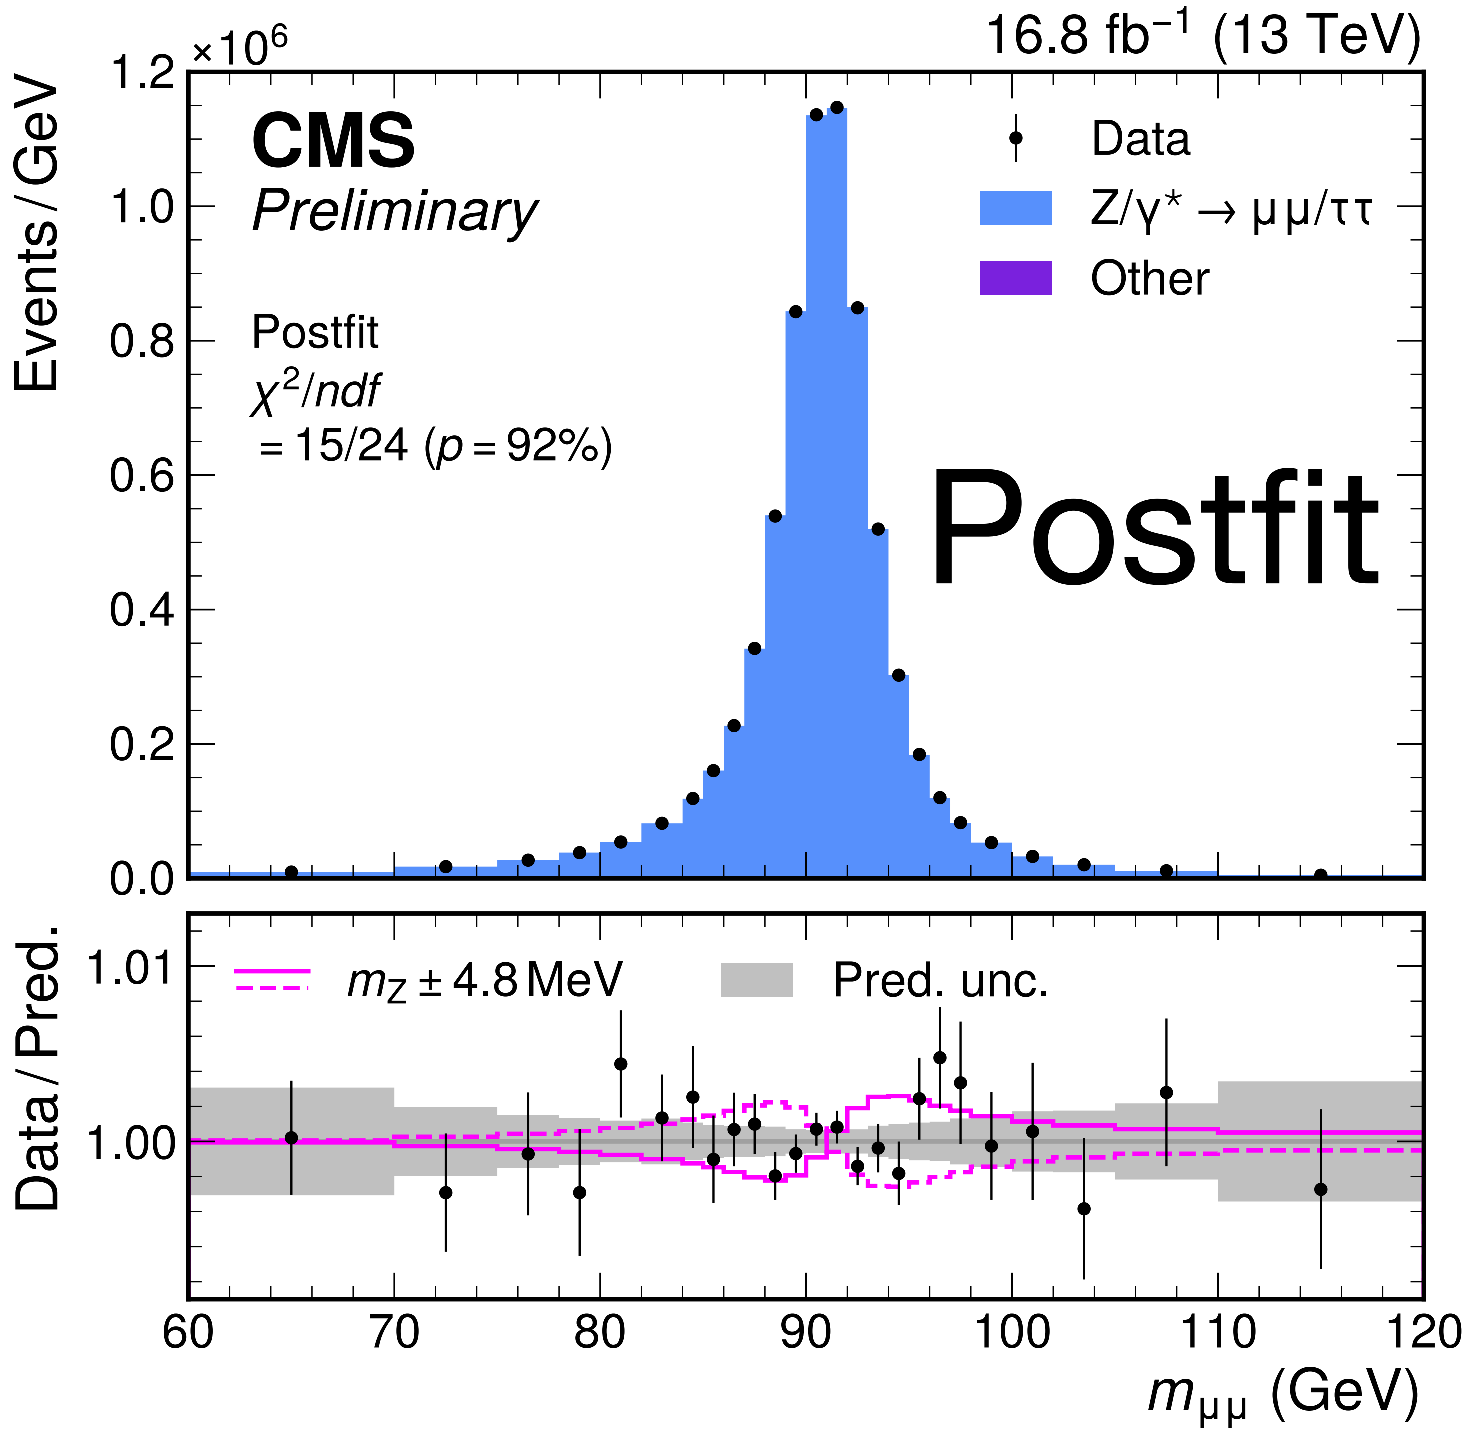
★ Extracting m_Z from fit to $m_{\mu\mu}$

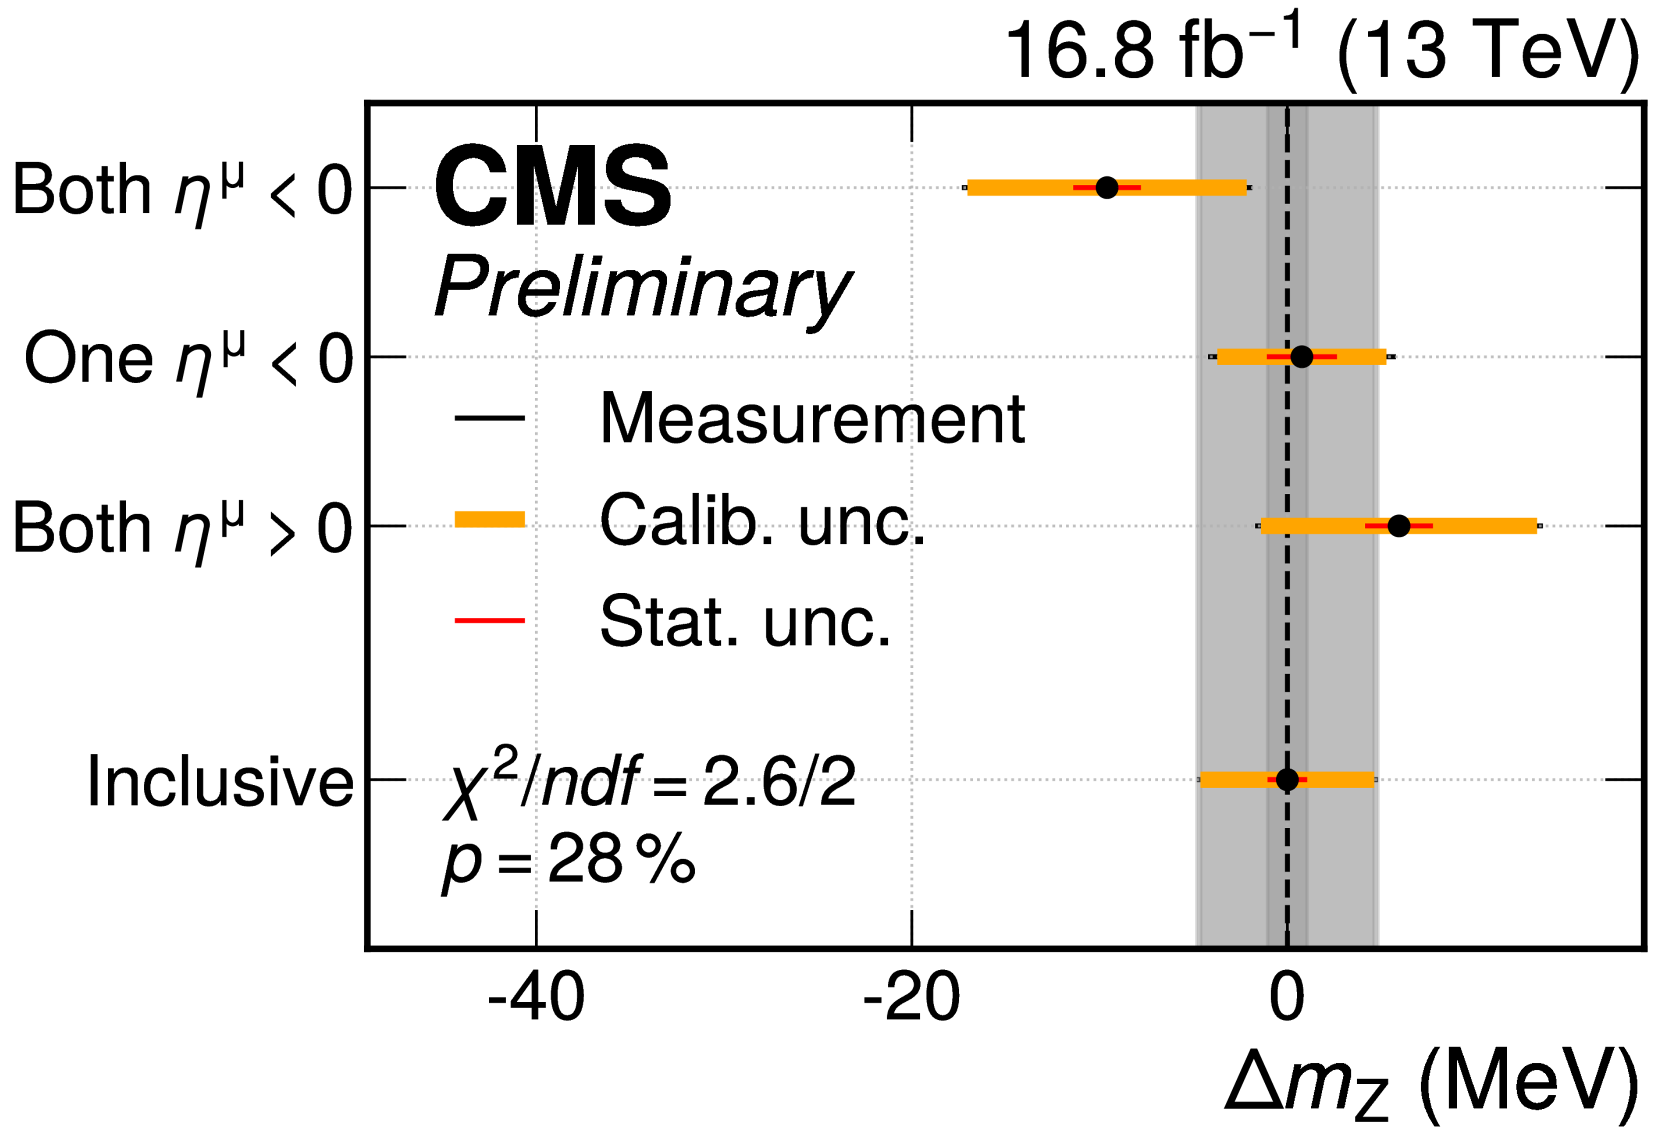
- Validation of experimental techniques by extracting m_Z
  - Binned likelihood fit to $m_{\mu\mu}$ in bins of signed η^{μ} of most forward muon

$$\mathbf{m_Z - m_Z^{PDG} = -2.2 \pm 4.8\ MeV} = -2.2 \pm 1.0\ (\text{stat}) \pm 4.7\ (\text{syst})\ \text{MeV}$$

- Not (yet) an independent measurement of m_Z
- Stability of result (calibration) validated across η^{μ}

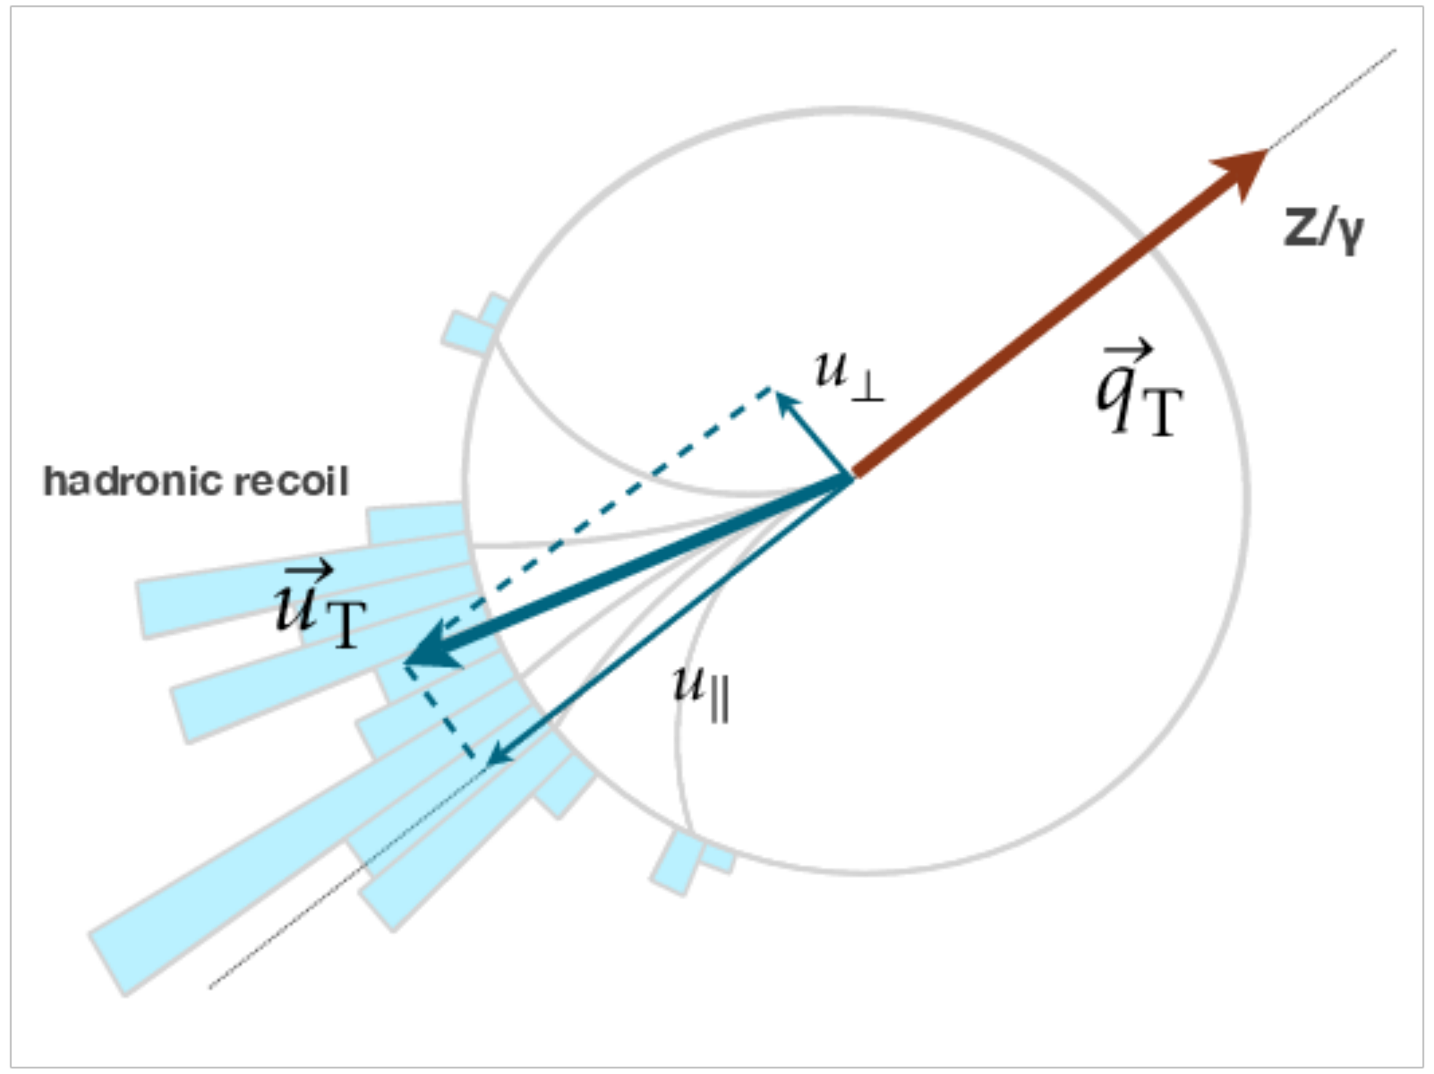


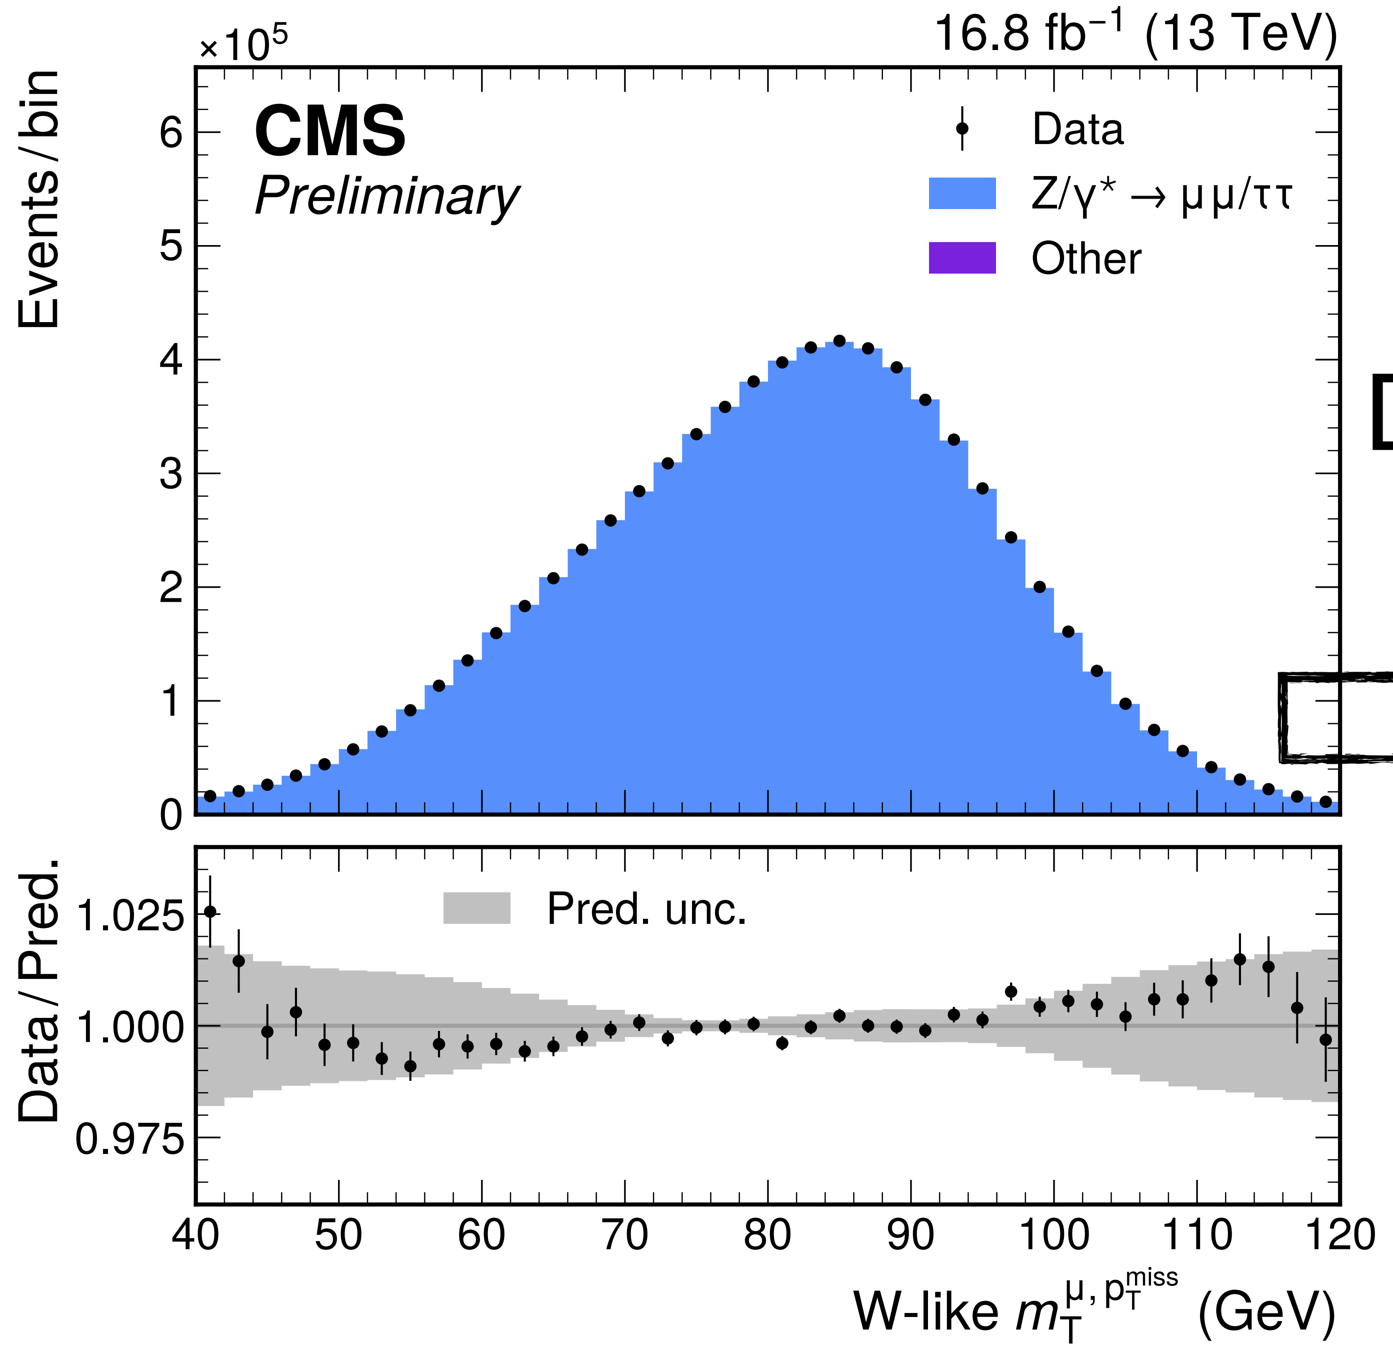




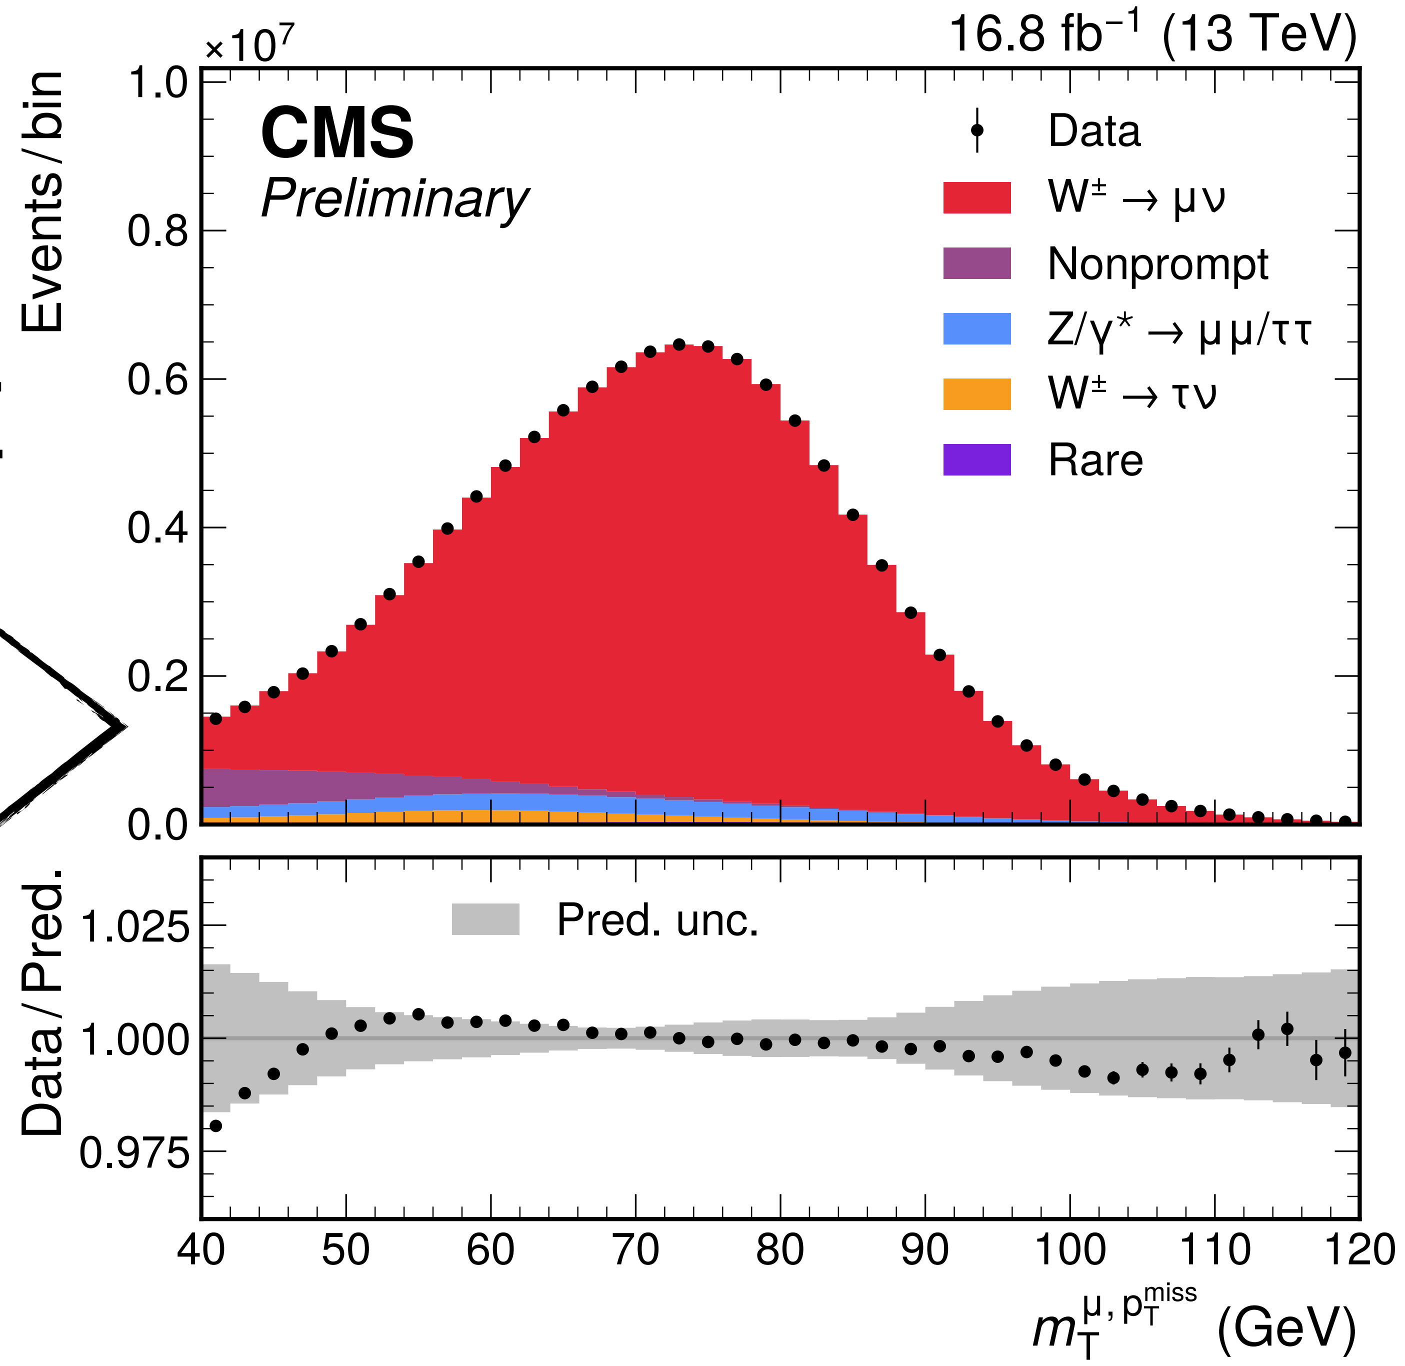
Recoil calibration

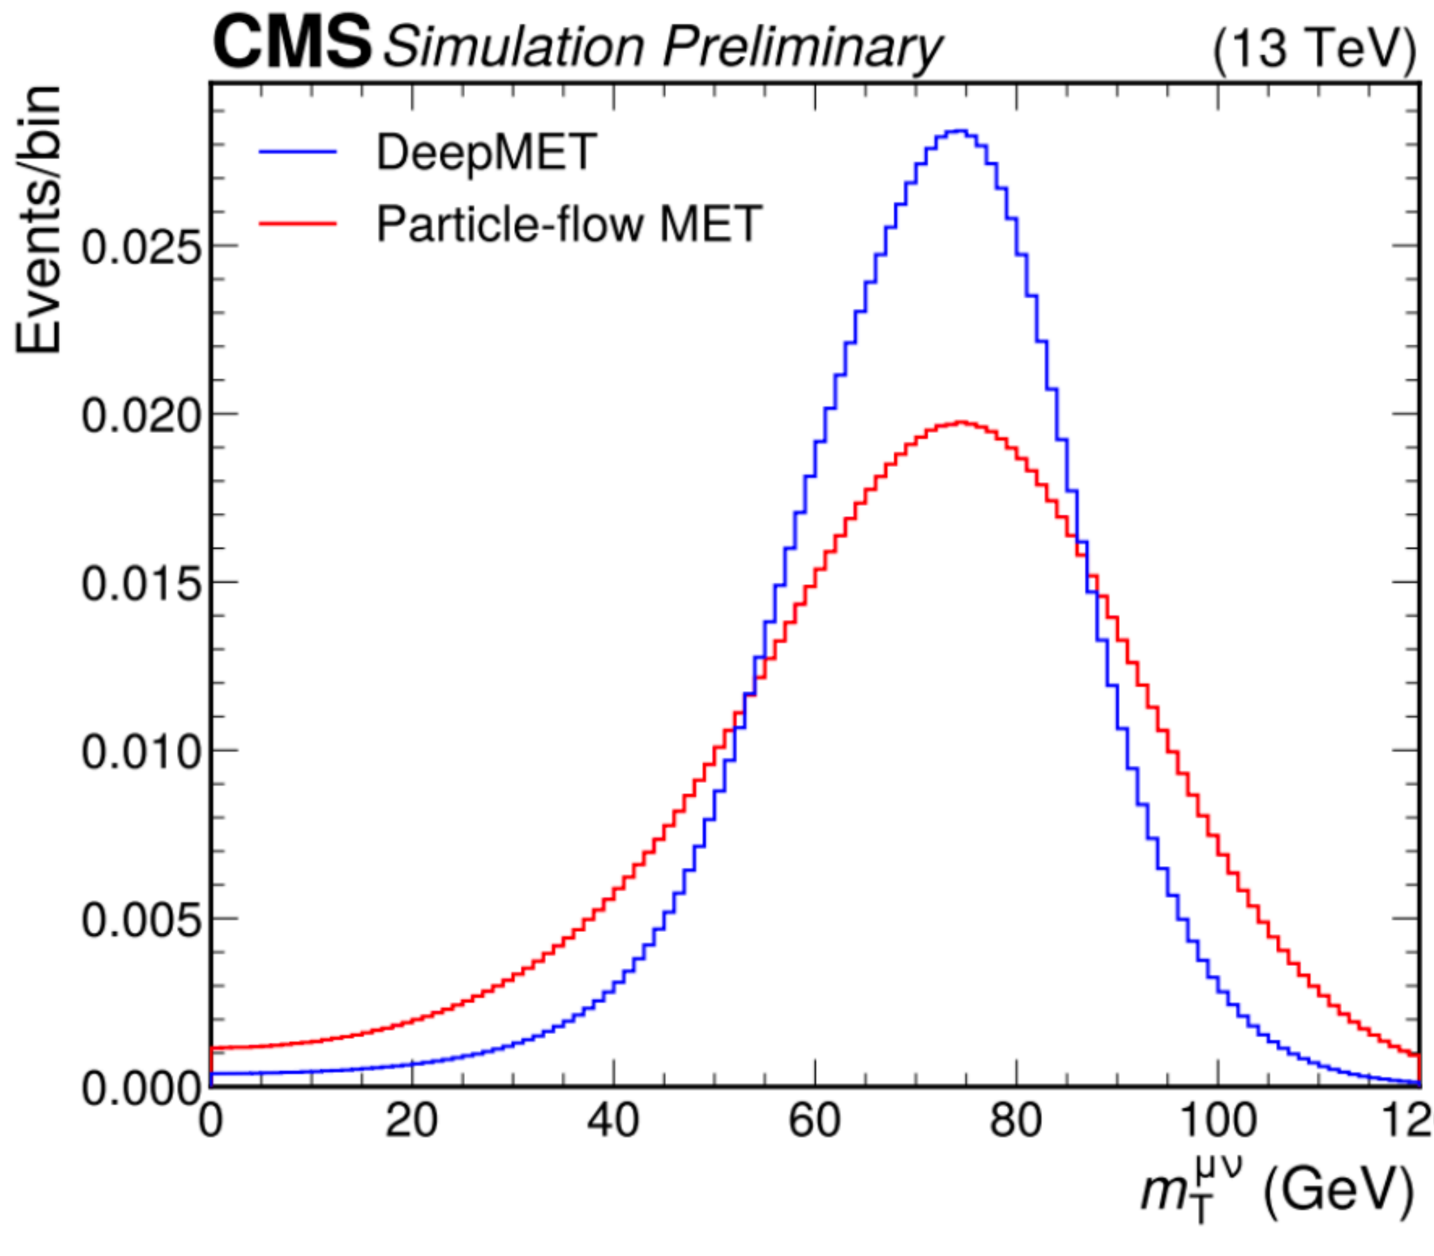
- p_T^{miss} enters the analysis via the signal ($m_T > 40$ GeV)
  - DeepMET gives improved resolution, better signal vs. background
- **Recoil calibrations from dimuon data** improve modelling of p_T^{miss} in MC
  - Parameterization of recoil templates in bins of boson p_T
  - Applied to Z (validation) and W MC using the inverse CDF method





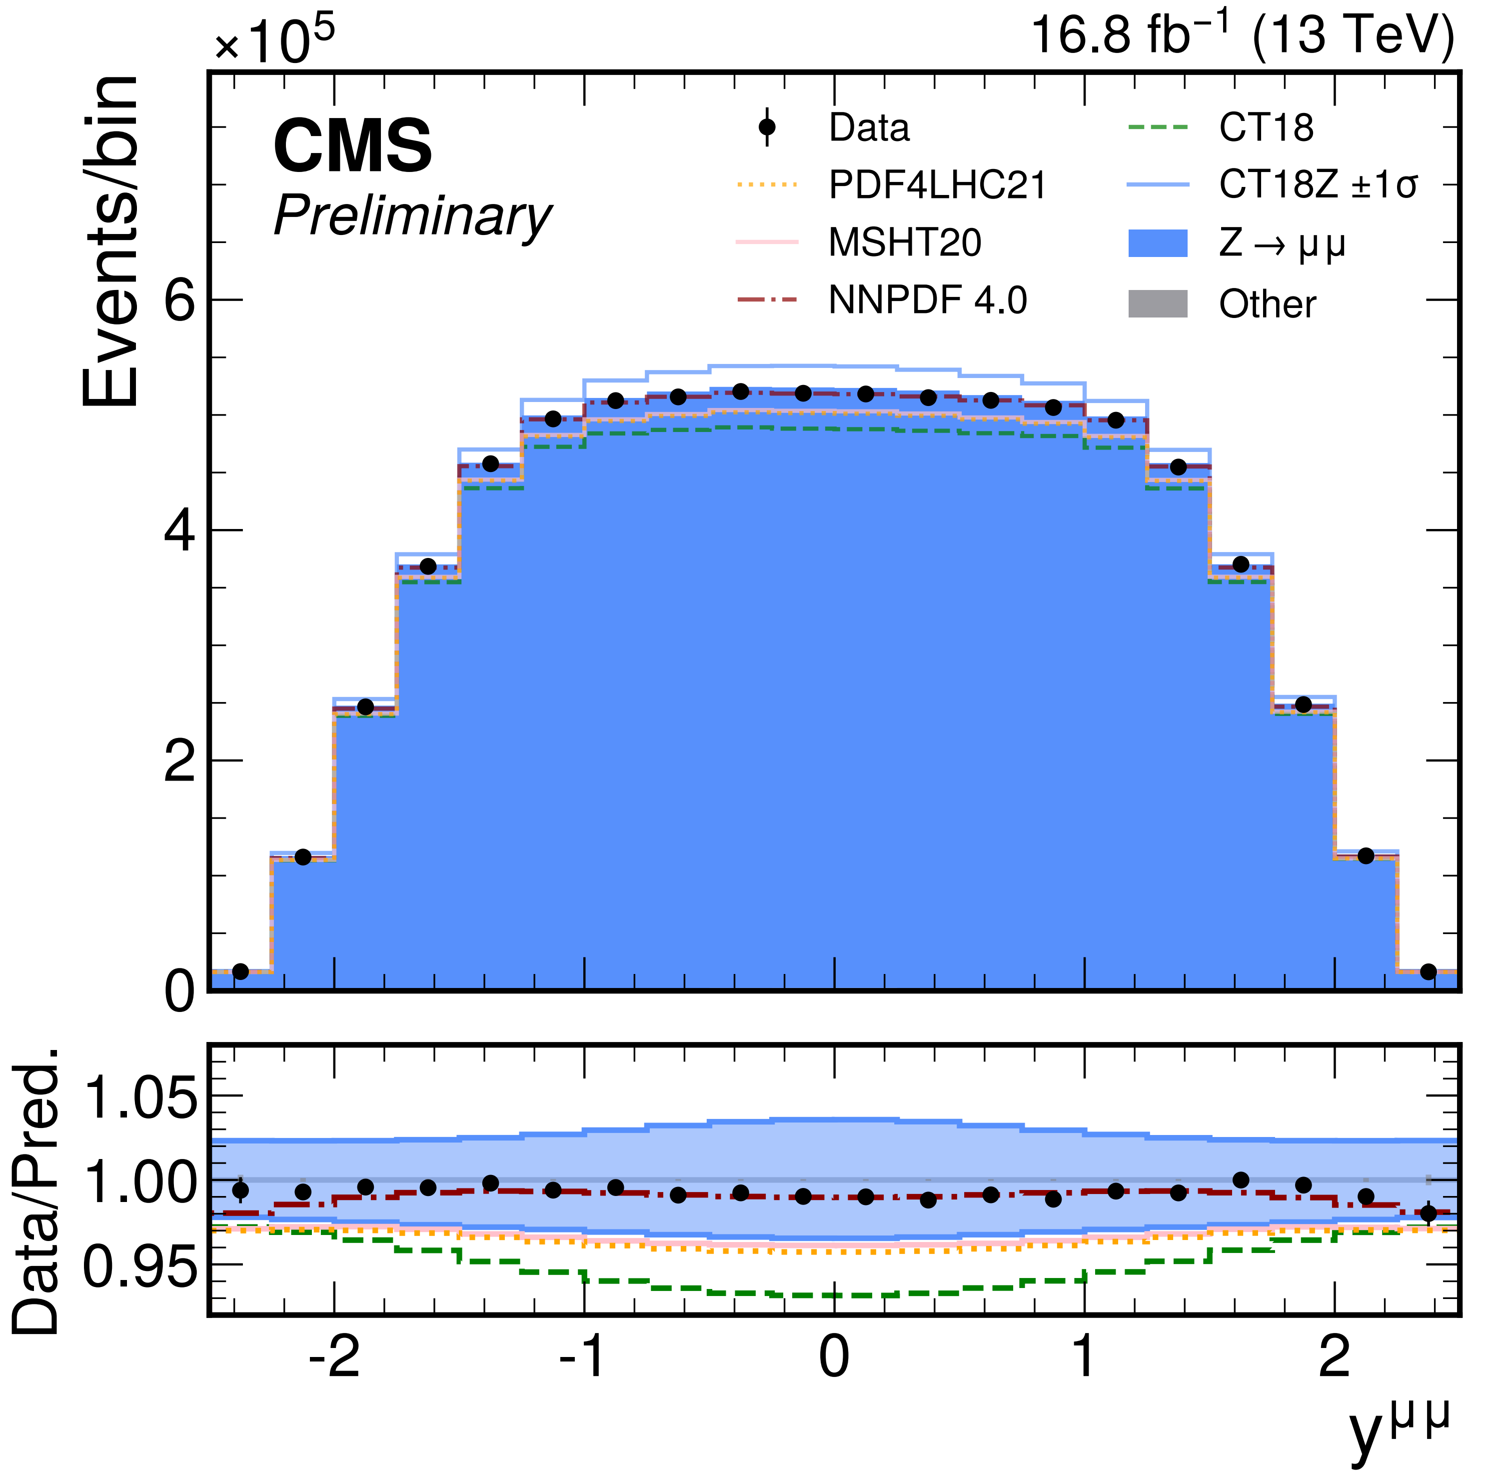
Derived from Z applied to W

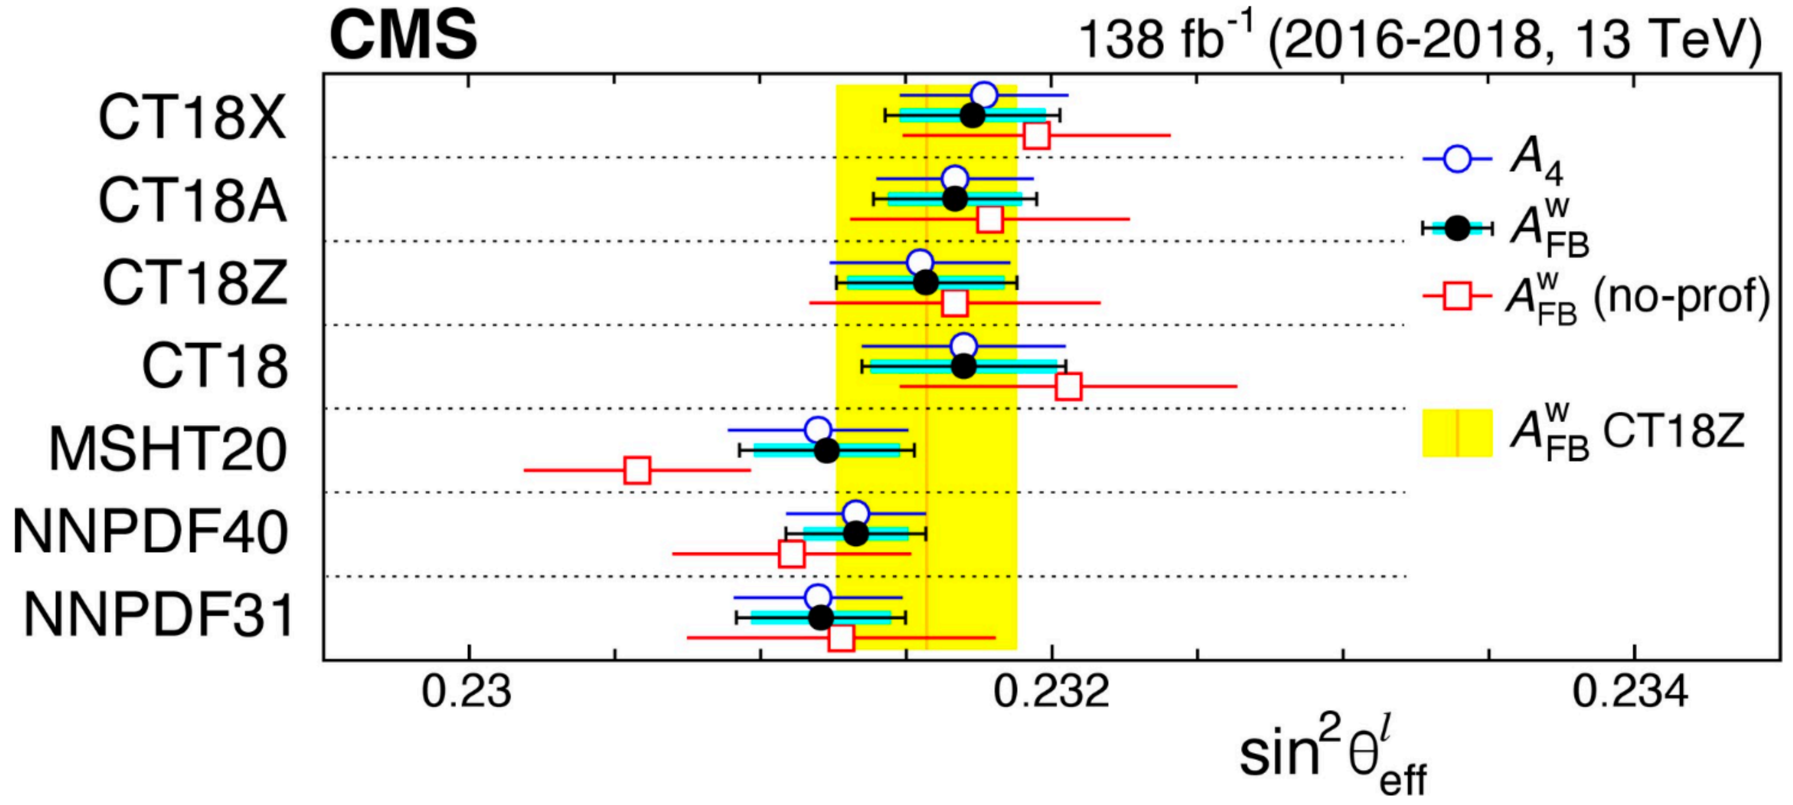


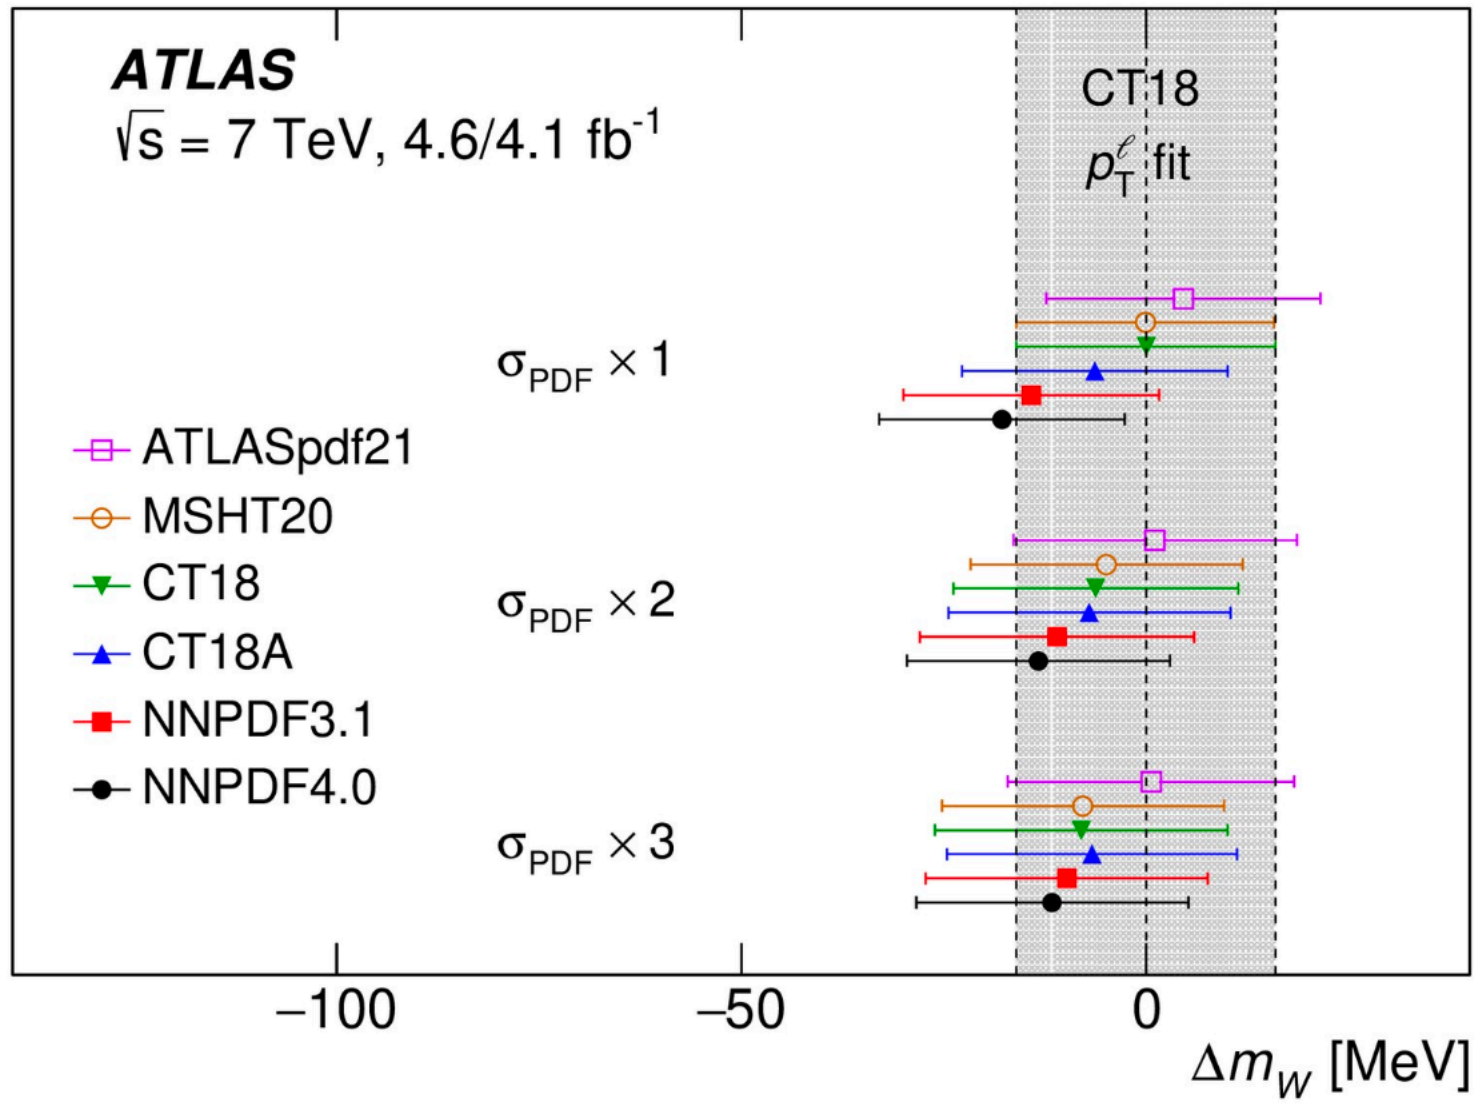


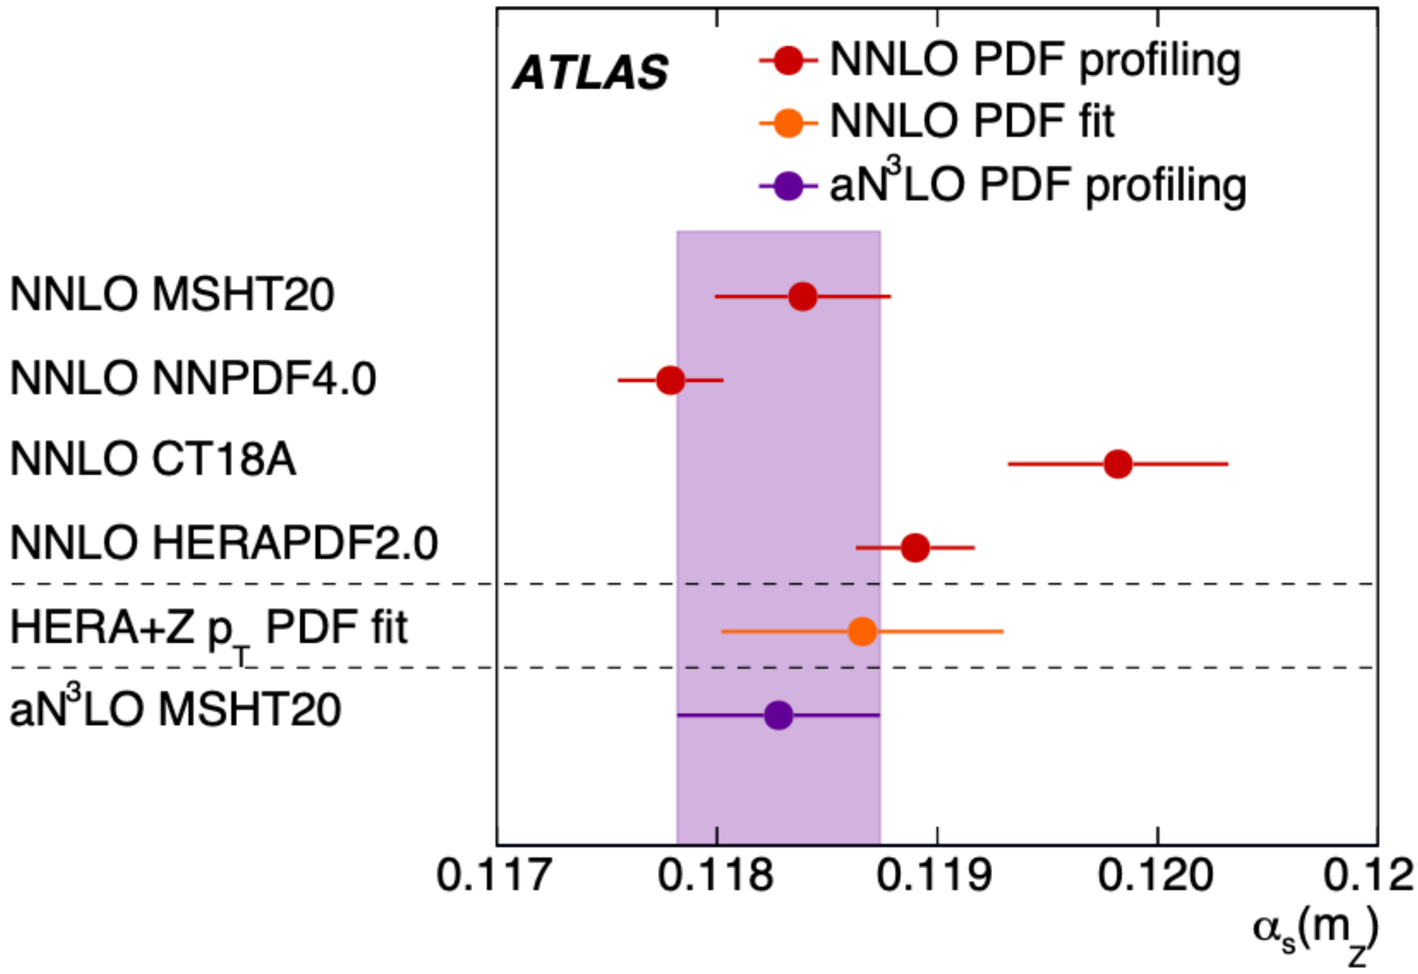
Theoretical modeling: PDF

- PDF is a **significant modeling uncertainty**
  - Modern PDF sets (MSHT20, NNPDF4.0, CT18 +…) in MiNNLO simulation as event weights
  - PDF uncertainties from the experimental data fitted+tolerances
    - Well defined statistical treatment, but…
    - Sets with different parameterisations+slightly different data, are not necessarily covered by uncertainties of others
  - **No PDFs include theory unc.** (approx. in special MSHT20, NNPDF)





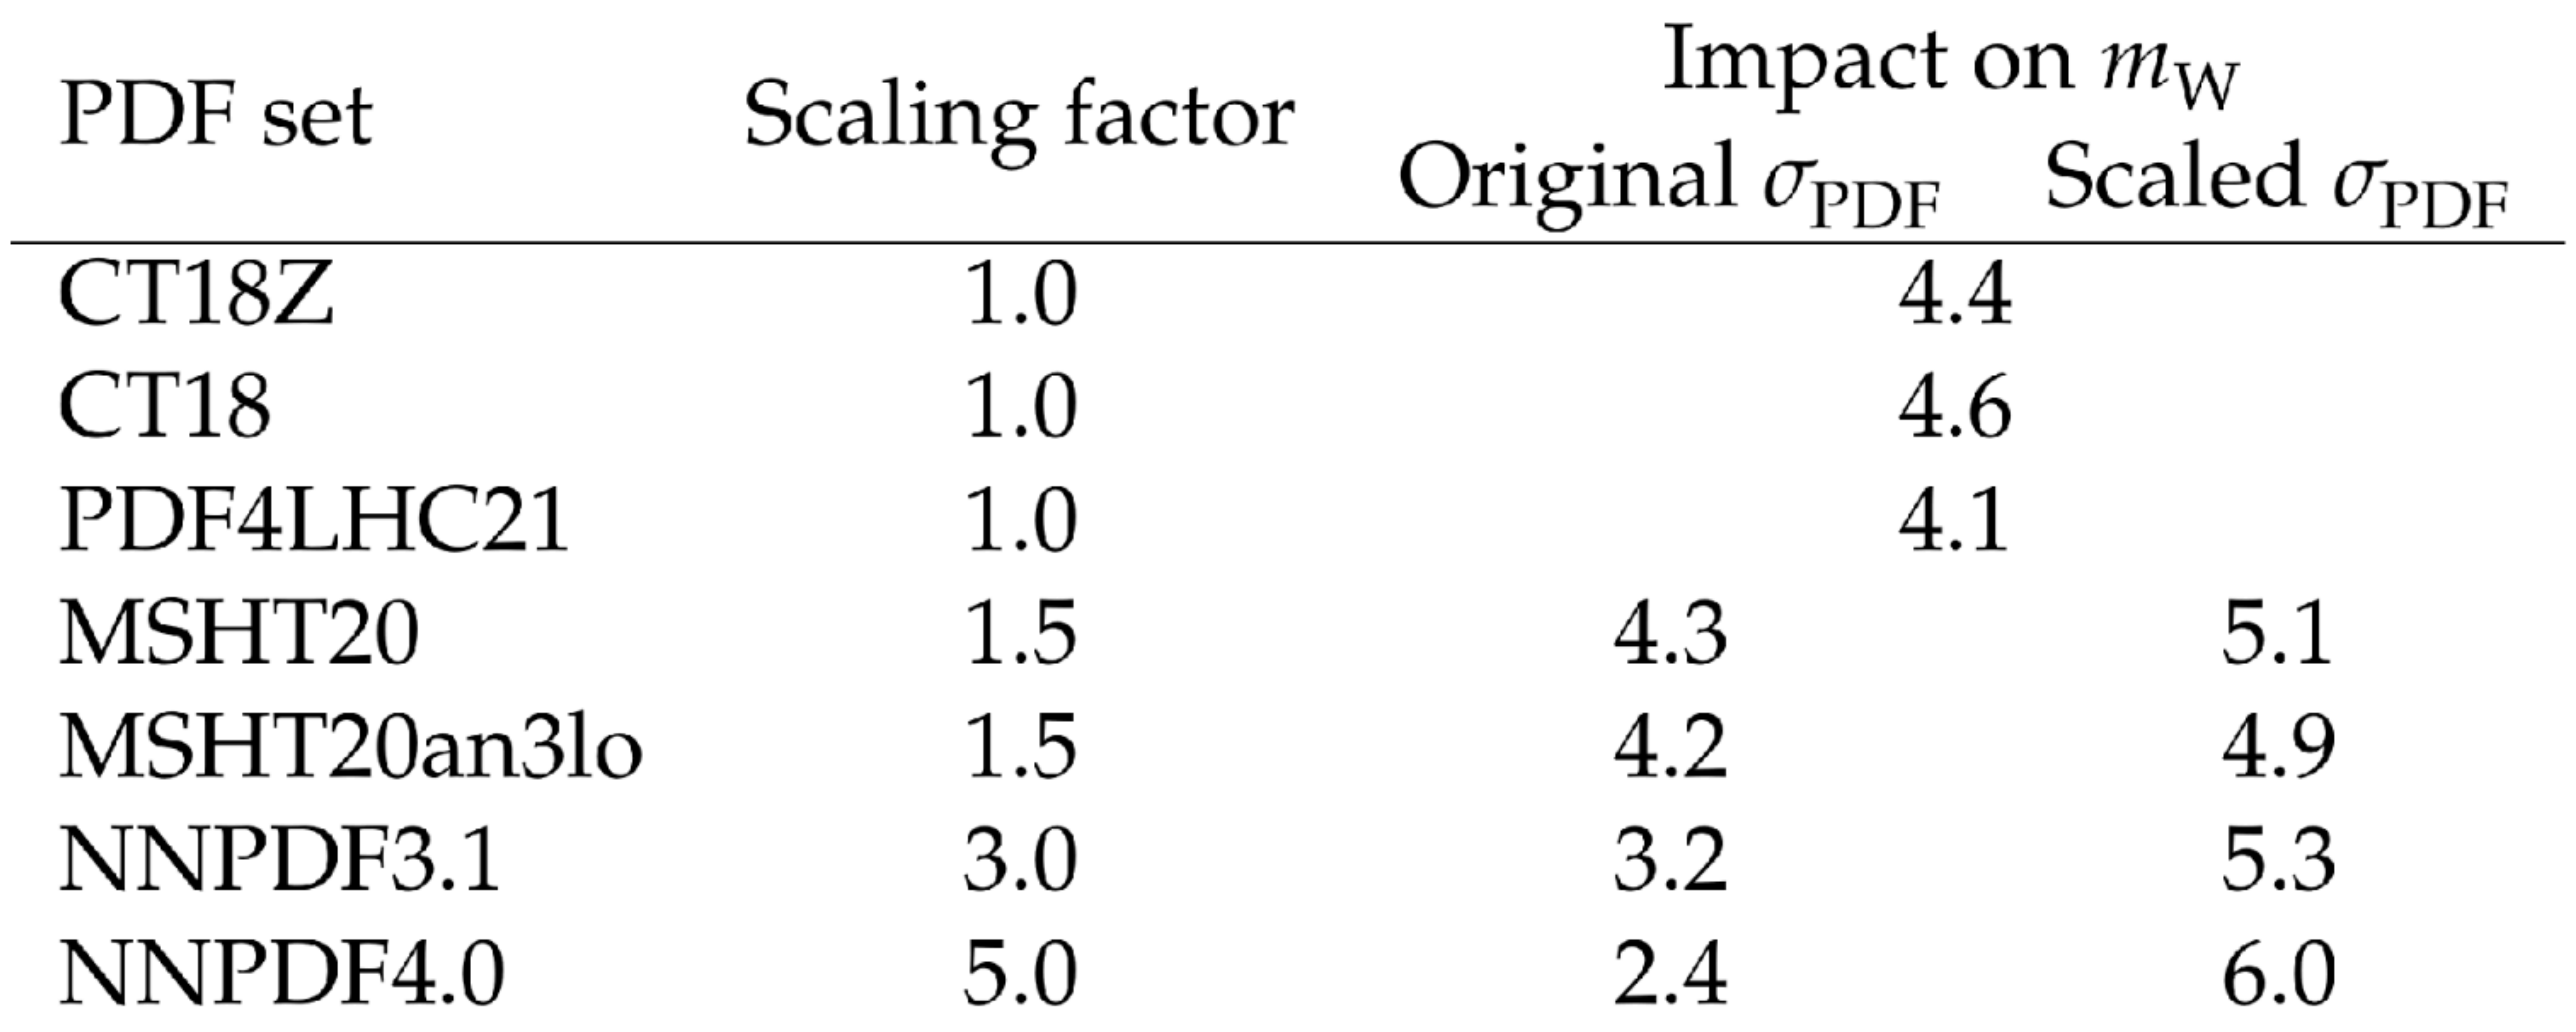




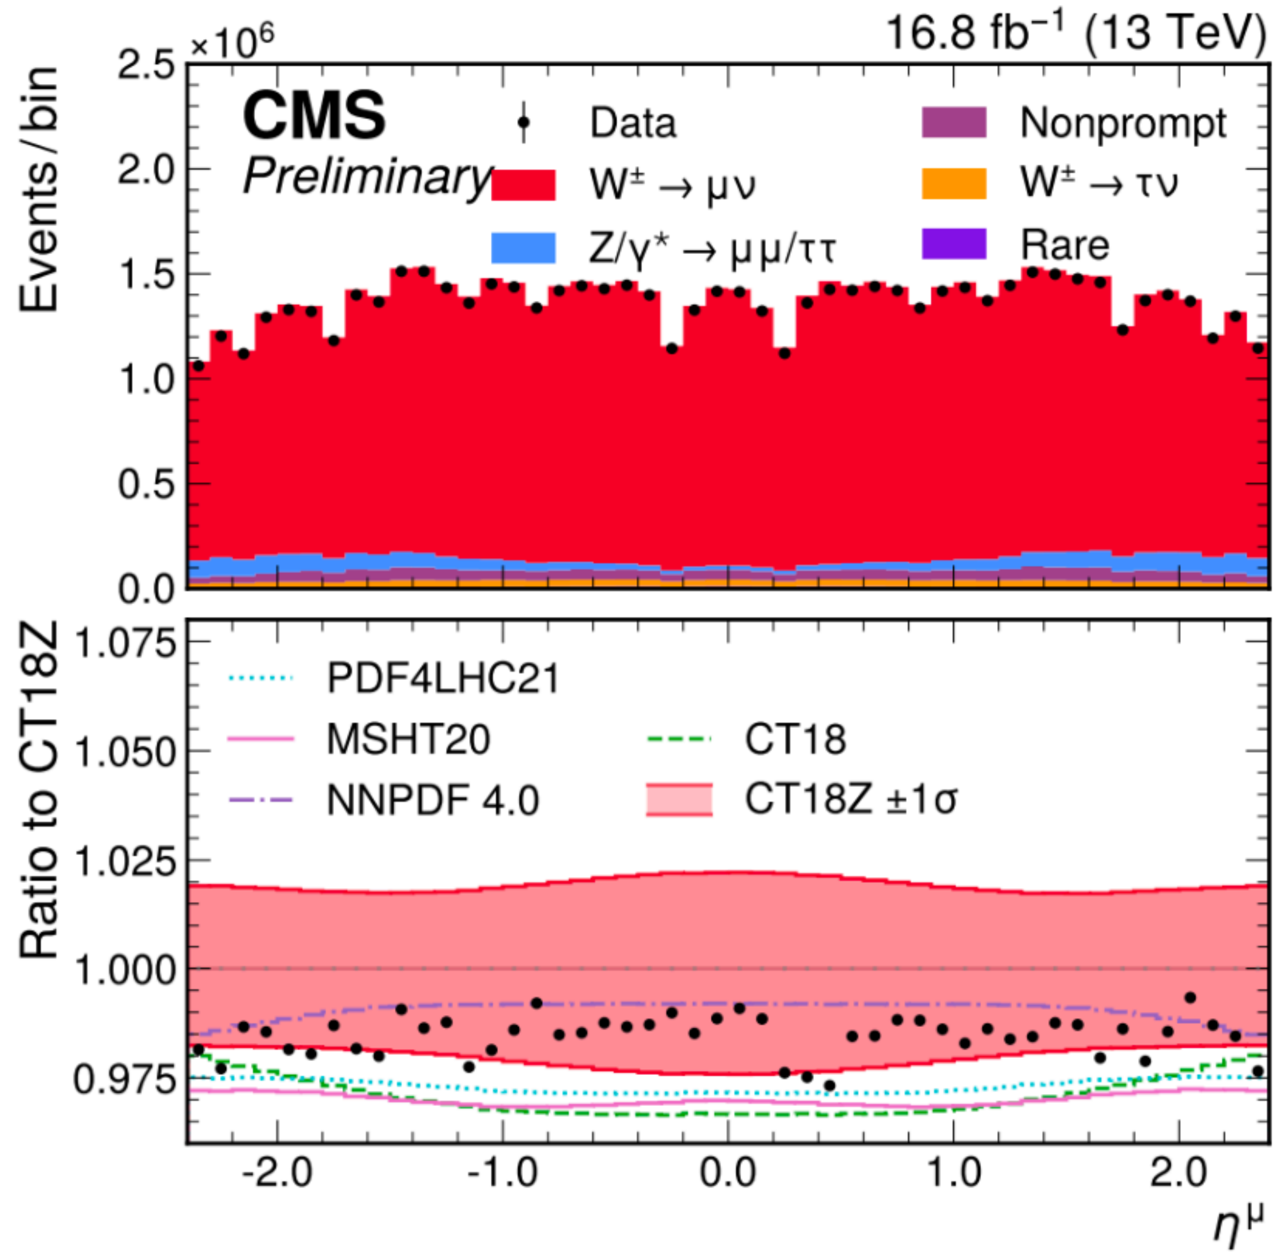
Theoretical modeling: PDF uncertainty

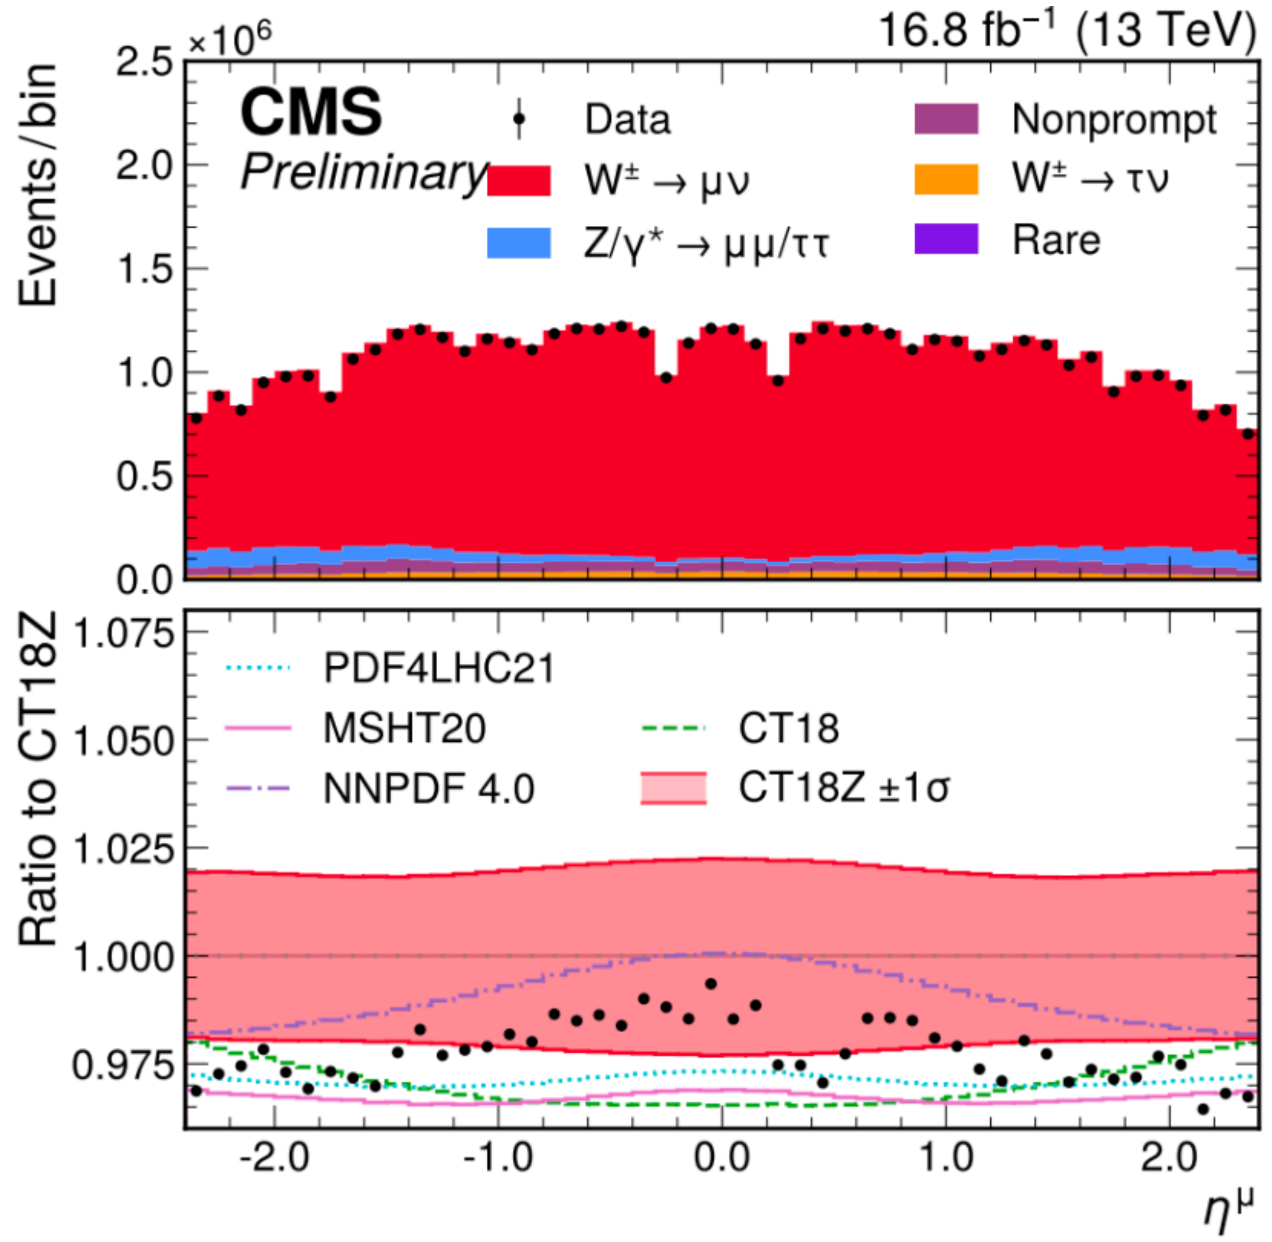
- Studied the impact of 8 modern PDF sets in our analysis
  - Compare consistency of sets with bias tests: treat one as MC prediction and another as pseudo data
  - Scaling factors for each PDF set uncertainty based on bias studies
  - Results for m_W with derived scaling and unscaled
- **Select CT18Z as nominal set** because of coverage of other sets and consistency with our data

➡4.4 MeV in m_W



PDF set	Scaling factor	Impact on m_W	
		Original σ_{PDF}	Scaled σ_{PDF}
CT18Z	1.0	4.4	
CT18	1.0	4.6	
PDF4LHC21	1.0	4.1	
MSHT20	1.5	4.3	5.1
MSHT20an3lo	1.5	4.2	4.9
NNPDF3.1	3.0	3.2	5.3
NNPDF4.0	5.0	2.4	6.0

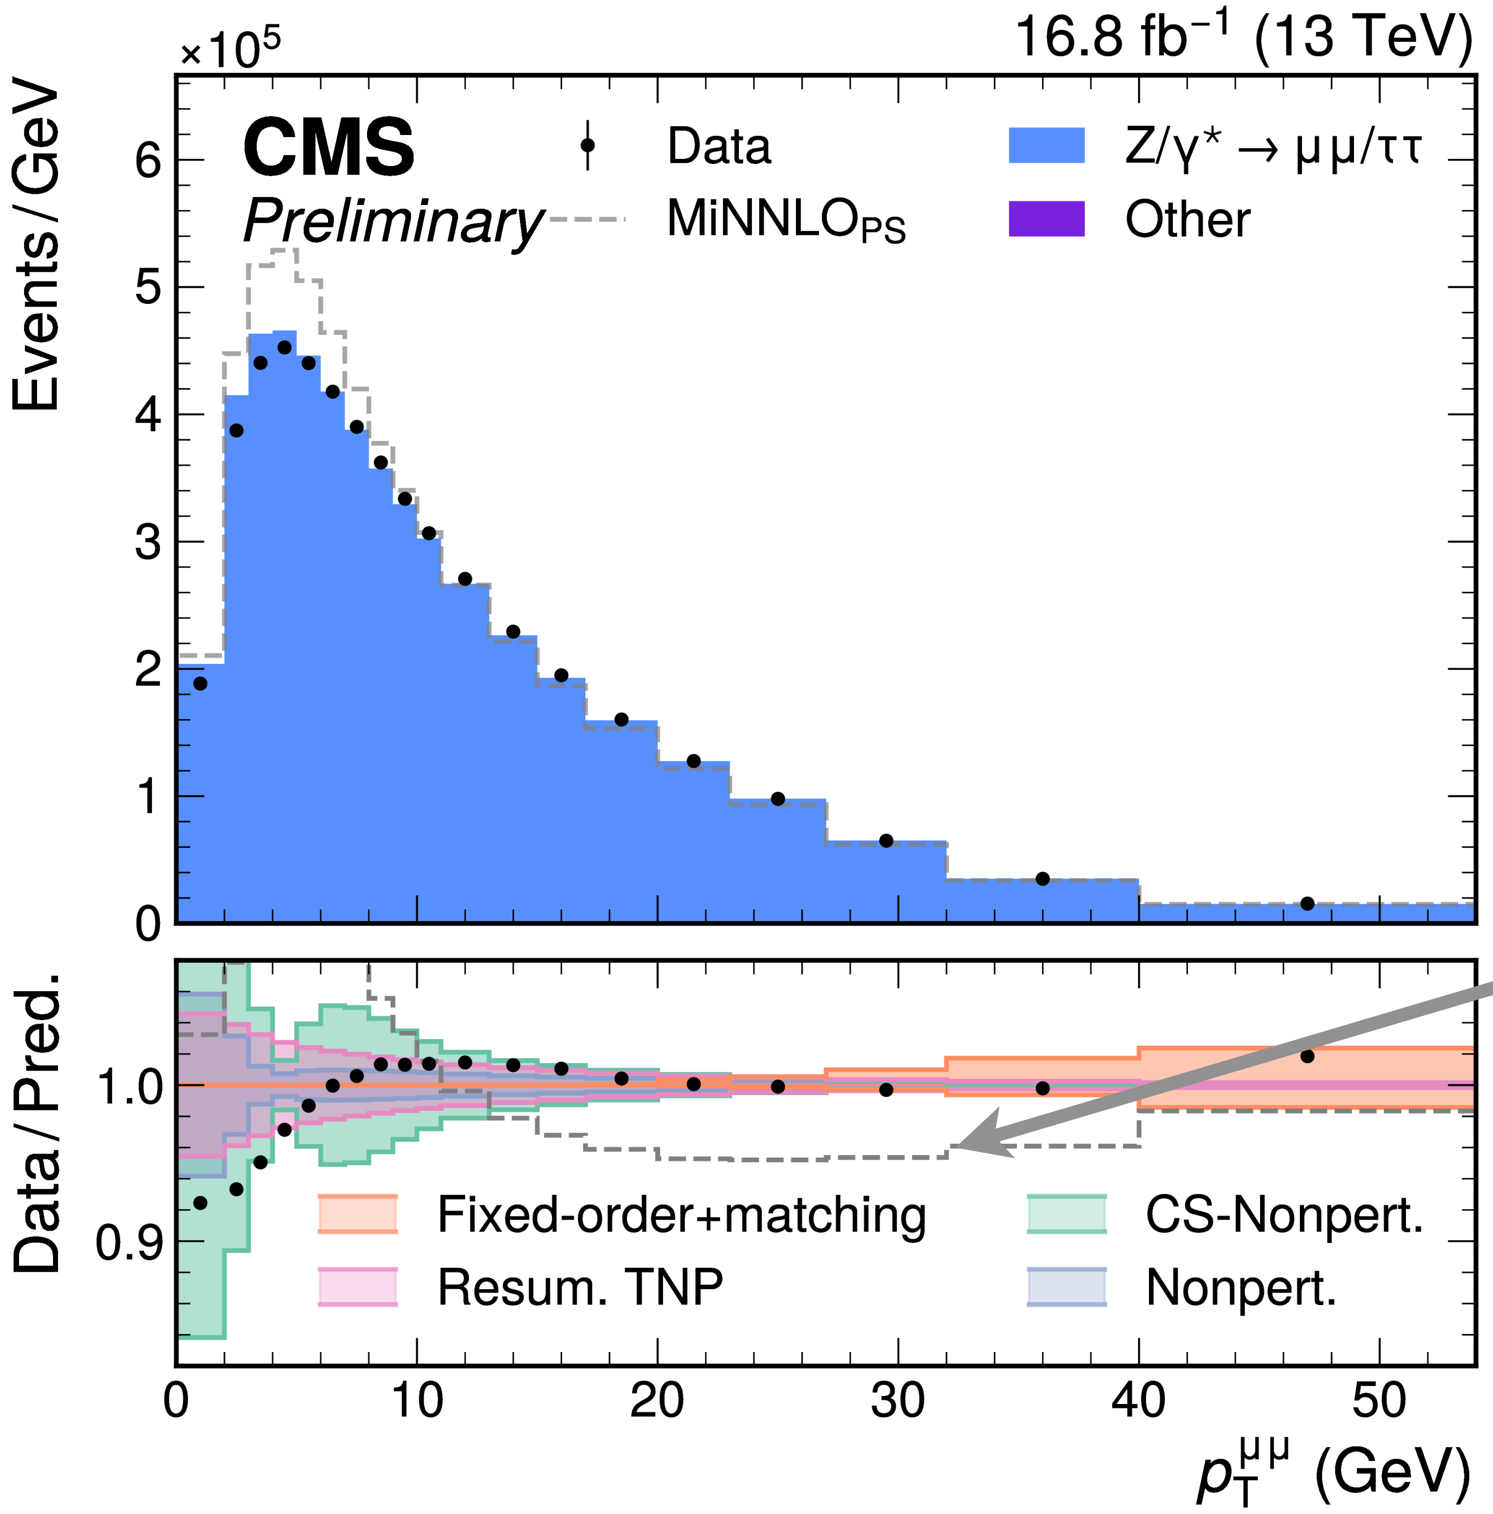




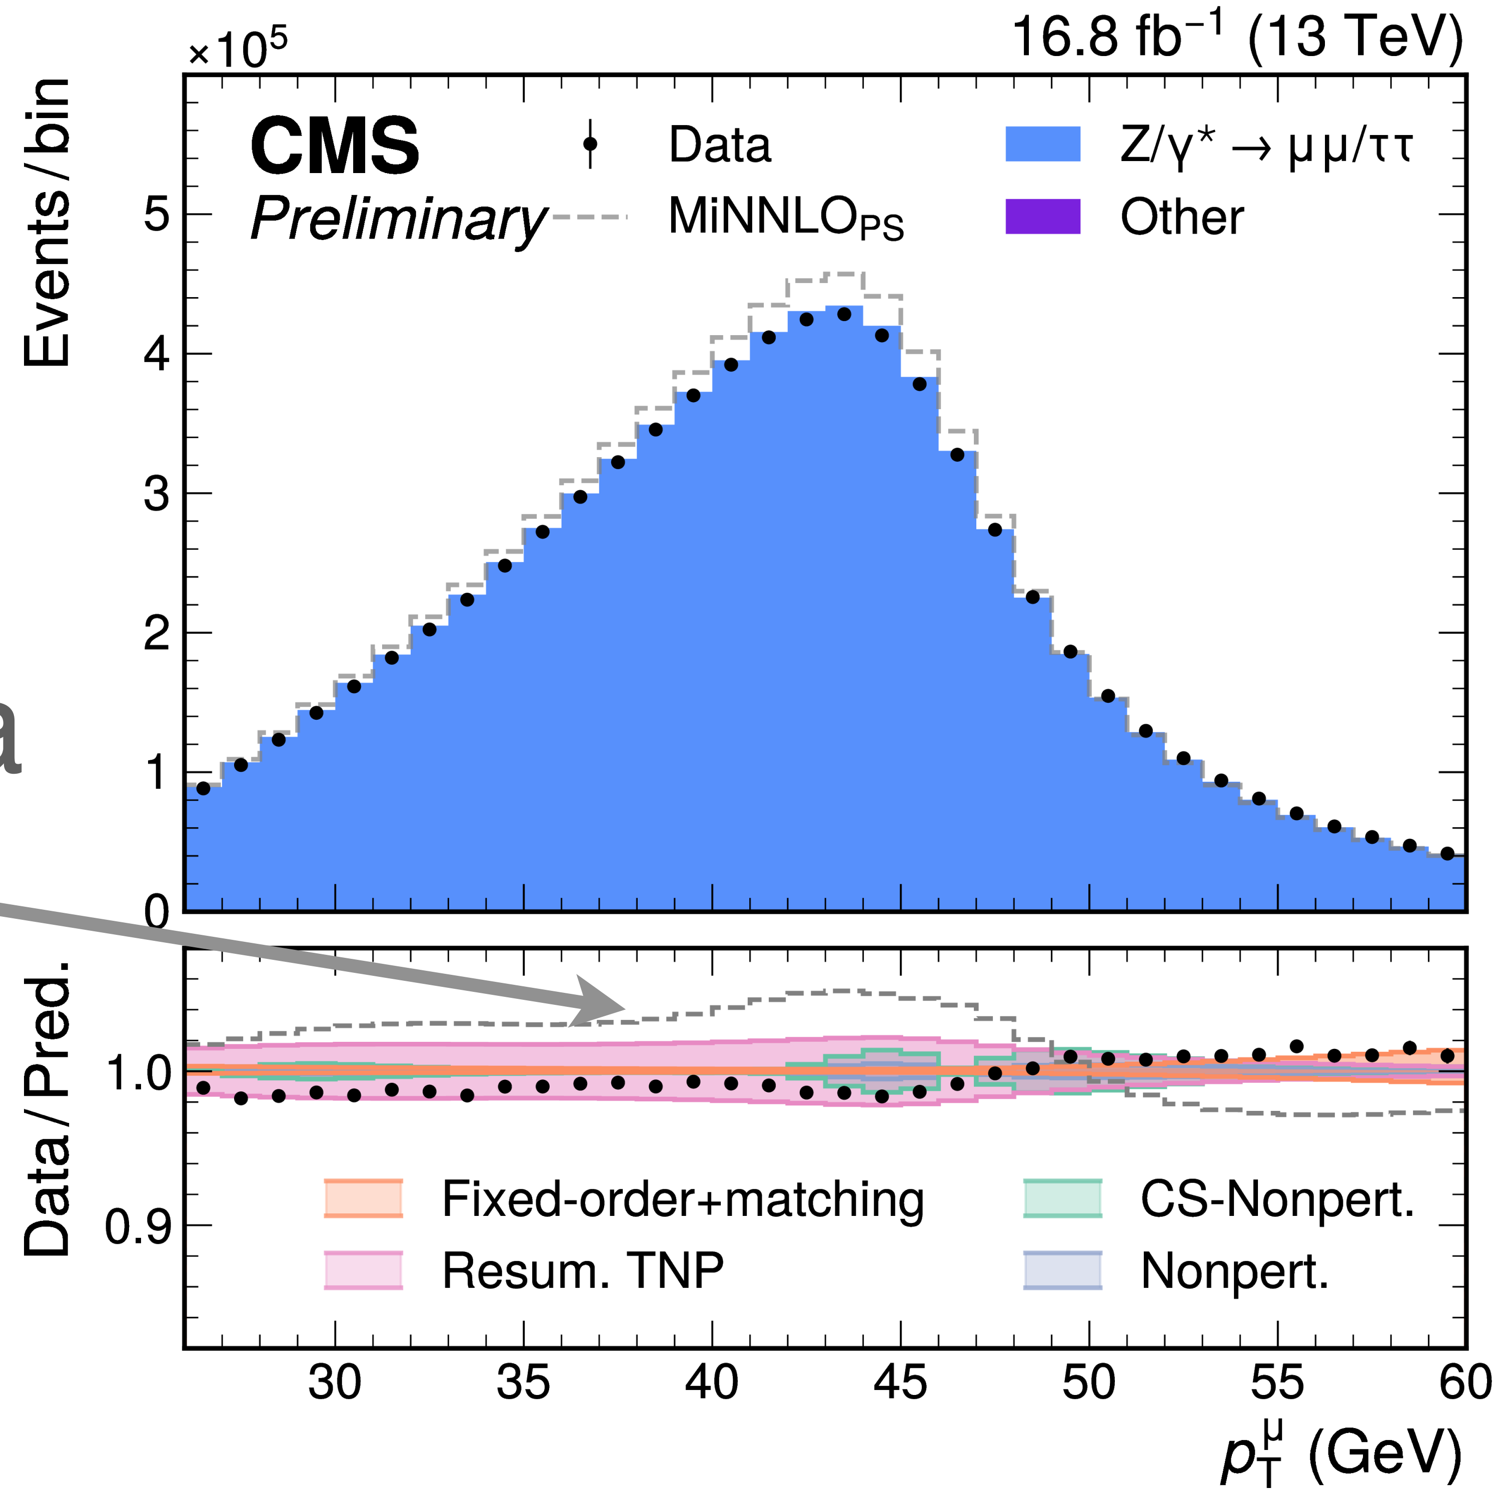
p_T^V modeling and uncertainties: overview

- Huge sample with with full detector simulation (4 B events) from MiNNLO_{PS}+Pythia+Photos++
  - Low-p_T^V dominated by non-perturbative effects, radiation of soft gluons (modelled by Pythia)
    - Improved accuracy from high-order calculation in resummation theory
    - Apply granular, high-stat. 2D **binned corrections to MiNNLO from SCETlib+DYTurbo**
- Do not derive corrections for simulation from the Z boson

➡Rely on accurate predictions + robust model of uncertainties, Z boson only as testing ground



MiNNLO_{PS}+Pythia
Uncorrected



ATLAS: tune Pythia to p_T^Z (5 MeV unc.)

CDF: Tune Resbos+reduce unc. from data comparisons (2 MeV unc.)

Non-perturbative effects and uncertainty

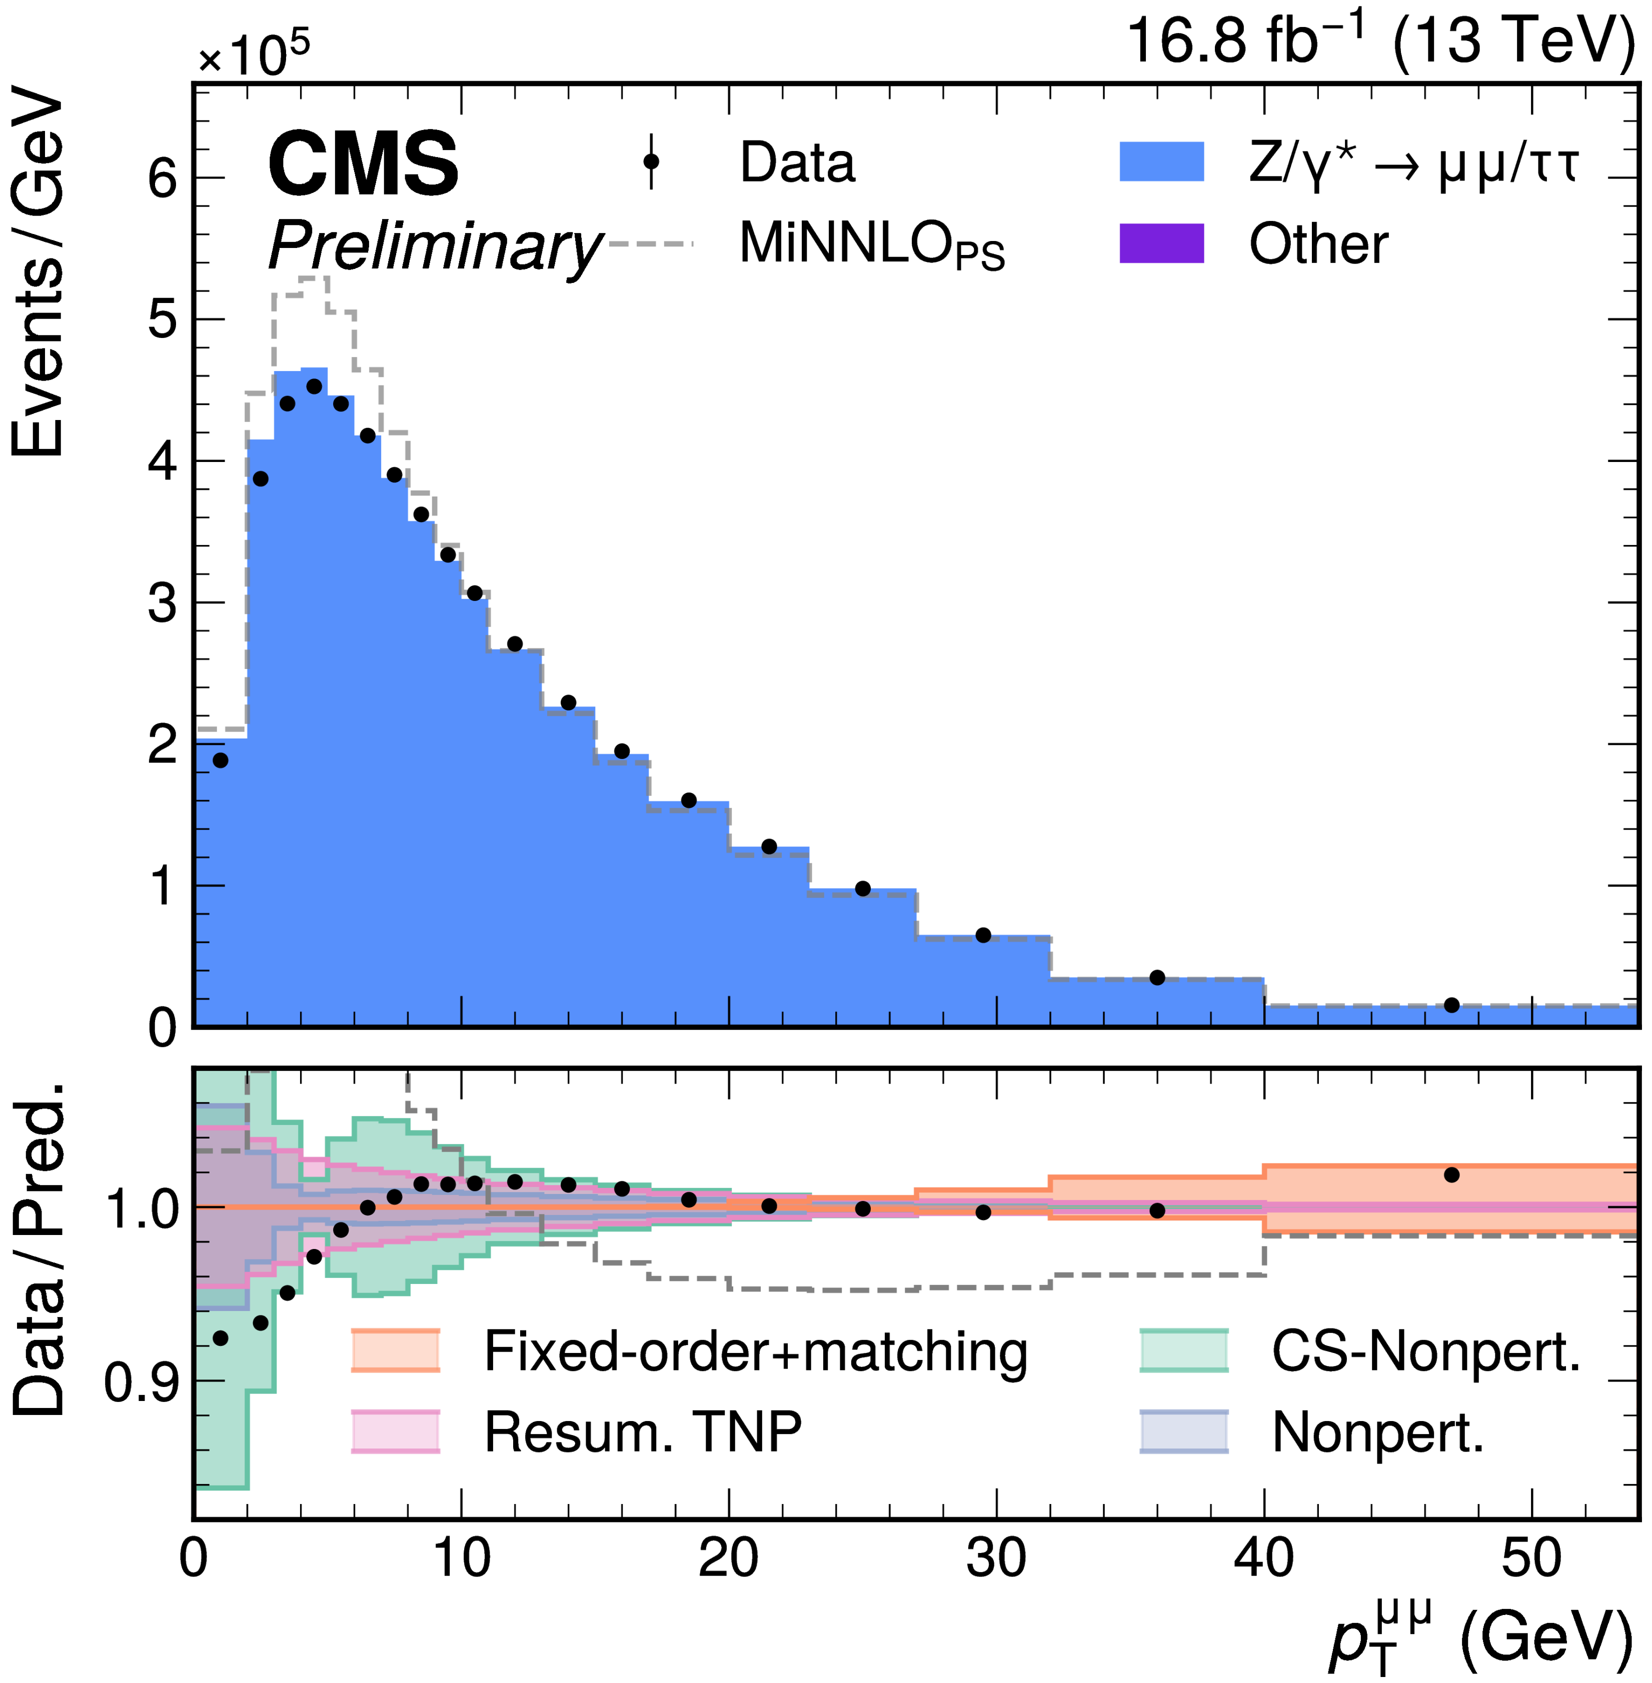
- PDF assumes parton momentum is entirely aligned with the proton motion
  - Residual motion in the proton: **low energy ⟹ nonperturbative (NP)**
- Use **phenomenological NP model in SCETlib** inspired by lattice QCD
  - Params untuned, loosely constrained, extracted separately for W and Z
  - Constrained by data: **~1.5 MeV unc. in m_W**

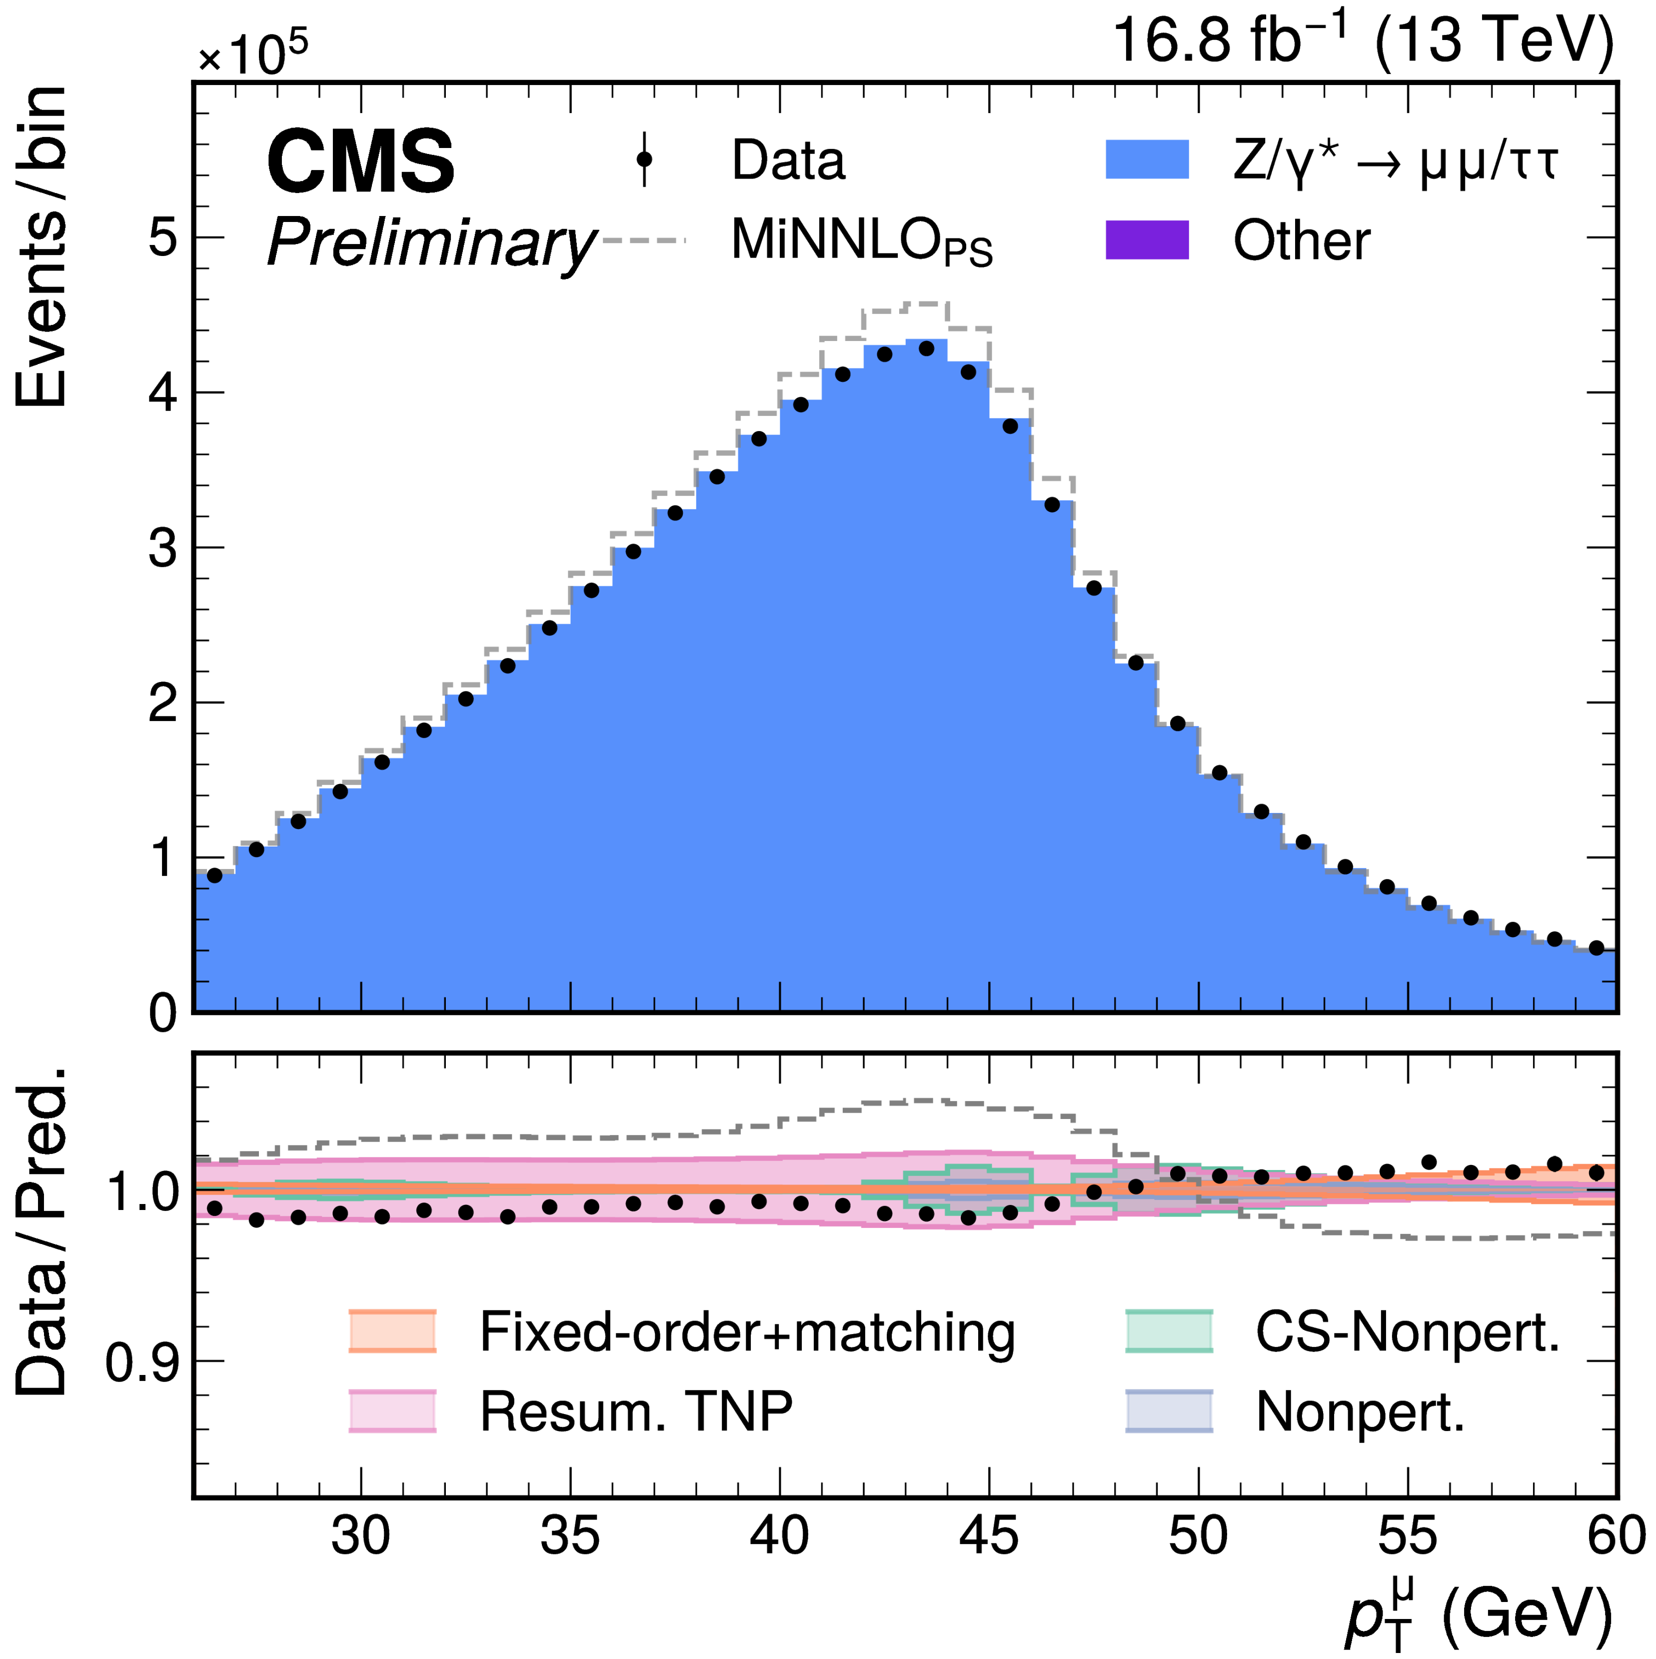
$$\tilde{\sigma}^{\rm np}(Y) = \left[1 + \overline{\Lambda}^{(2)}(Y)\, b_T^2\right]^2 \exp(-2\Lambda^{(4)}\, b_T^4)\,,$$
$$\overline{\Lambda}^{(2)}(Y) = \overline{\Lambda}^{(2)} + Y^2 \Delta\overline{\Lambda}^{(2)}\,.$$

arxiv:2201.07237

y-dependence as proxy for x and flavour dependence

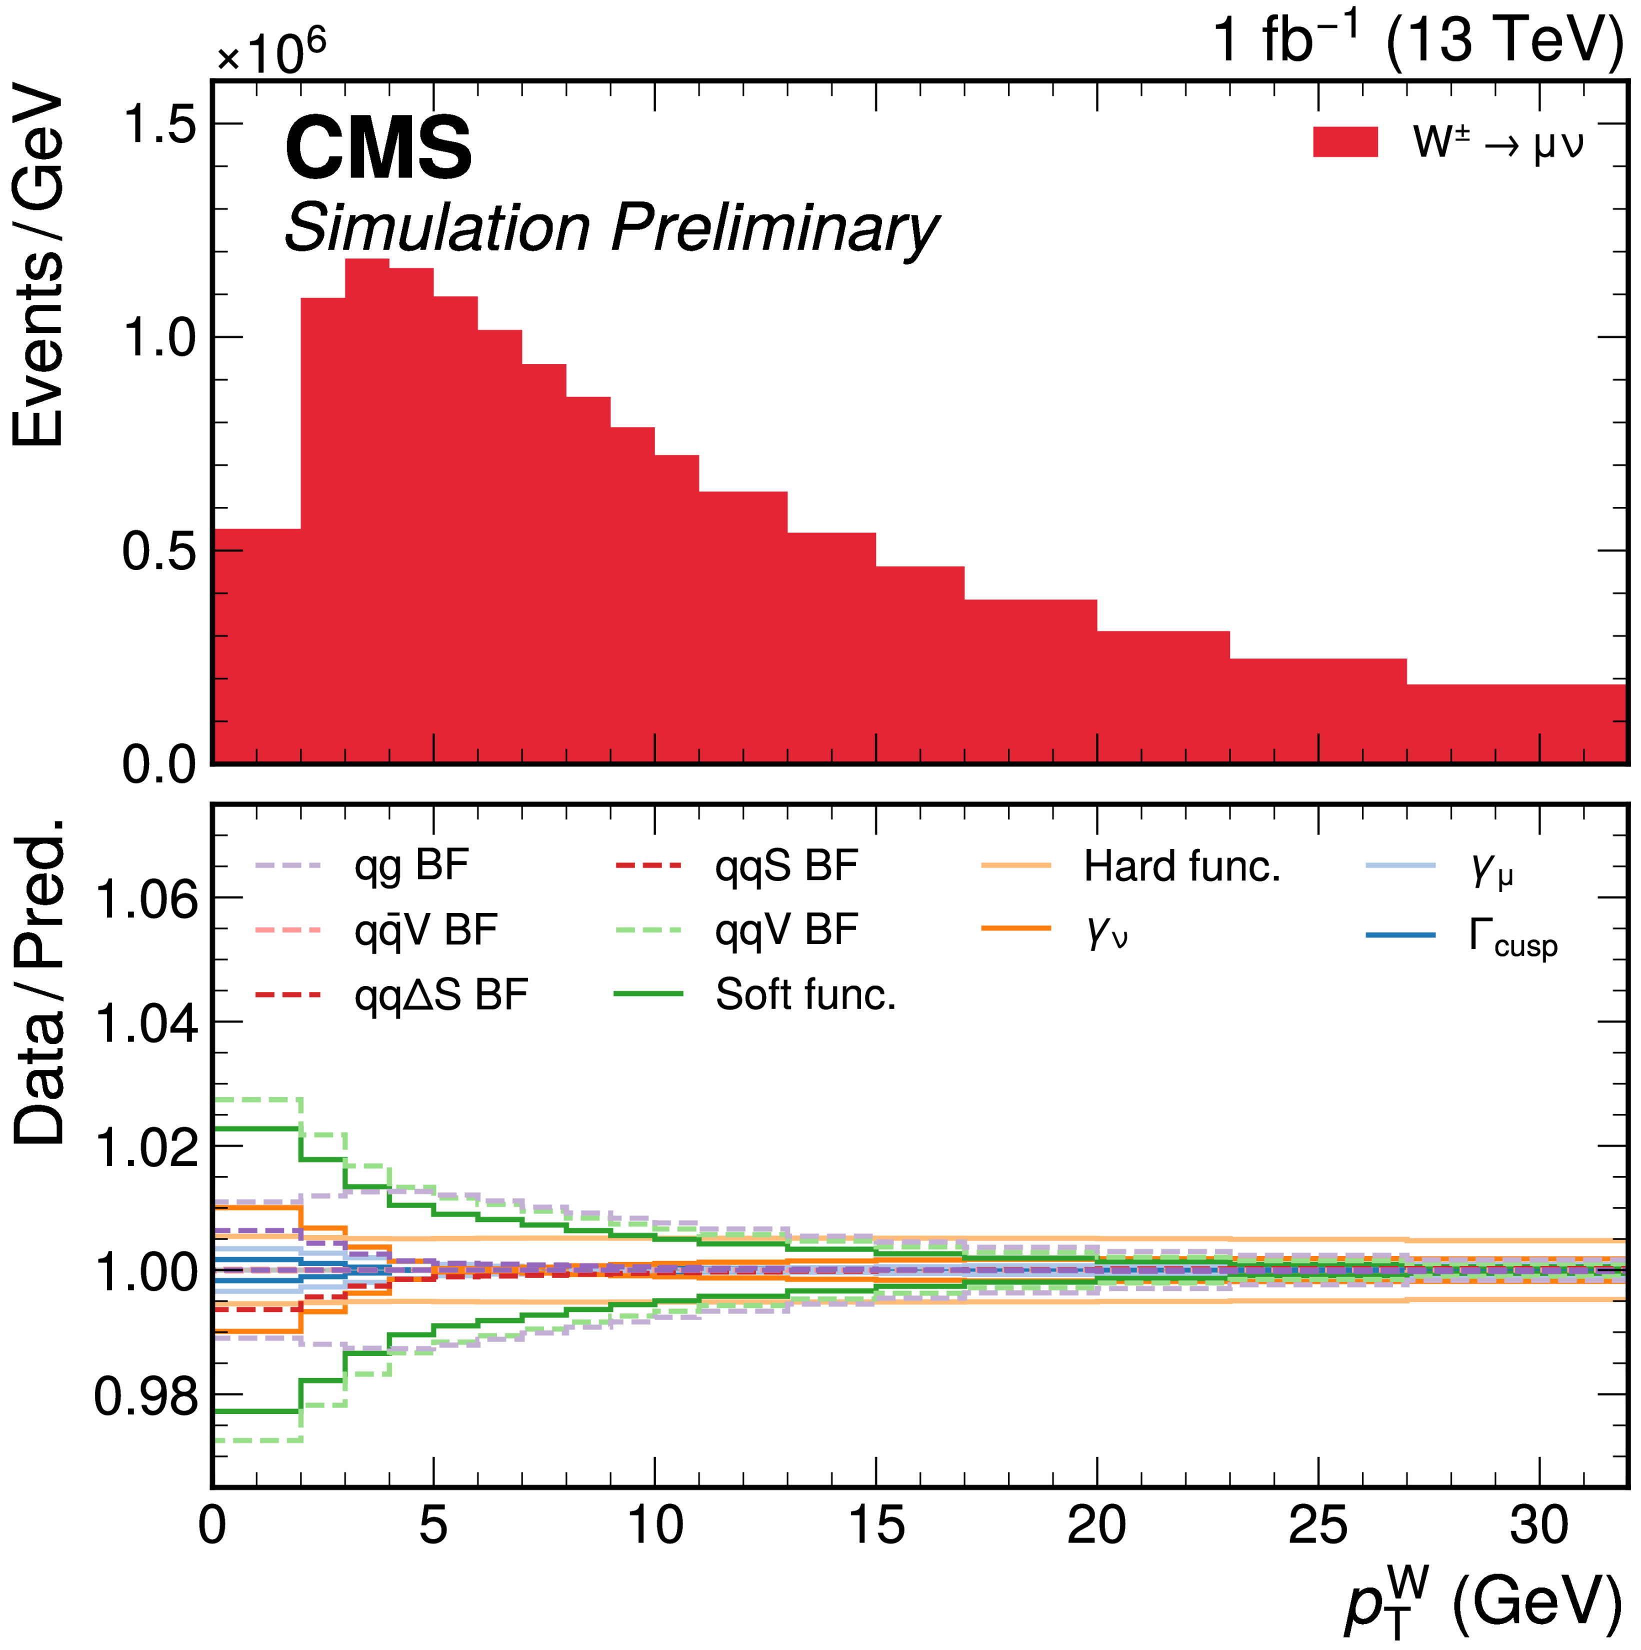
- Collins–Soper (CS) kernel universal (correlated for W and Z)
- Others (Gaussian intrinsic momentum) not correlated

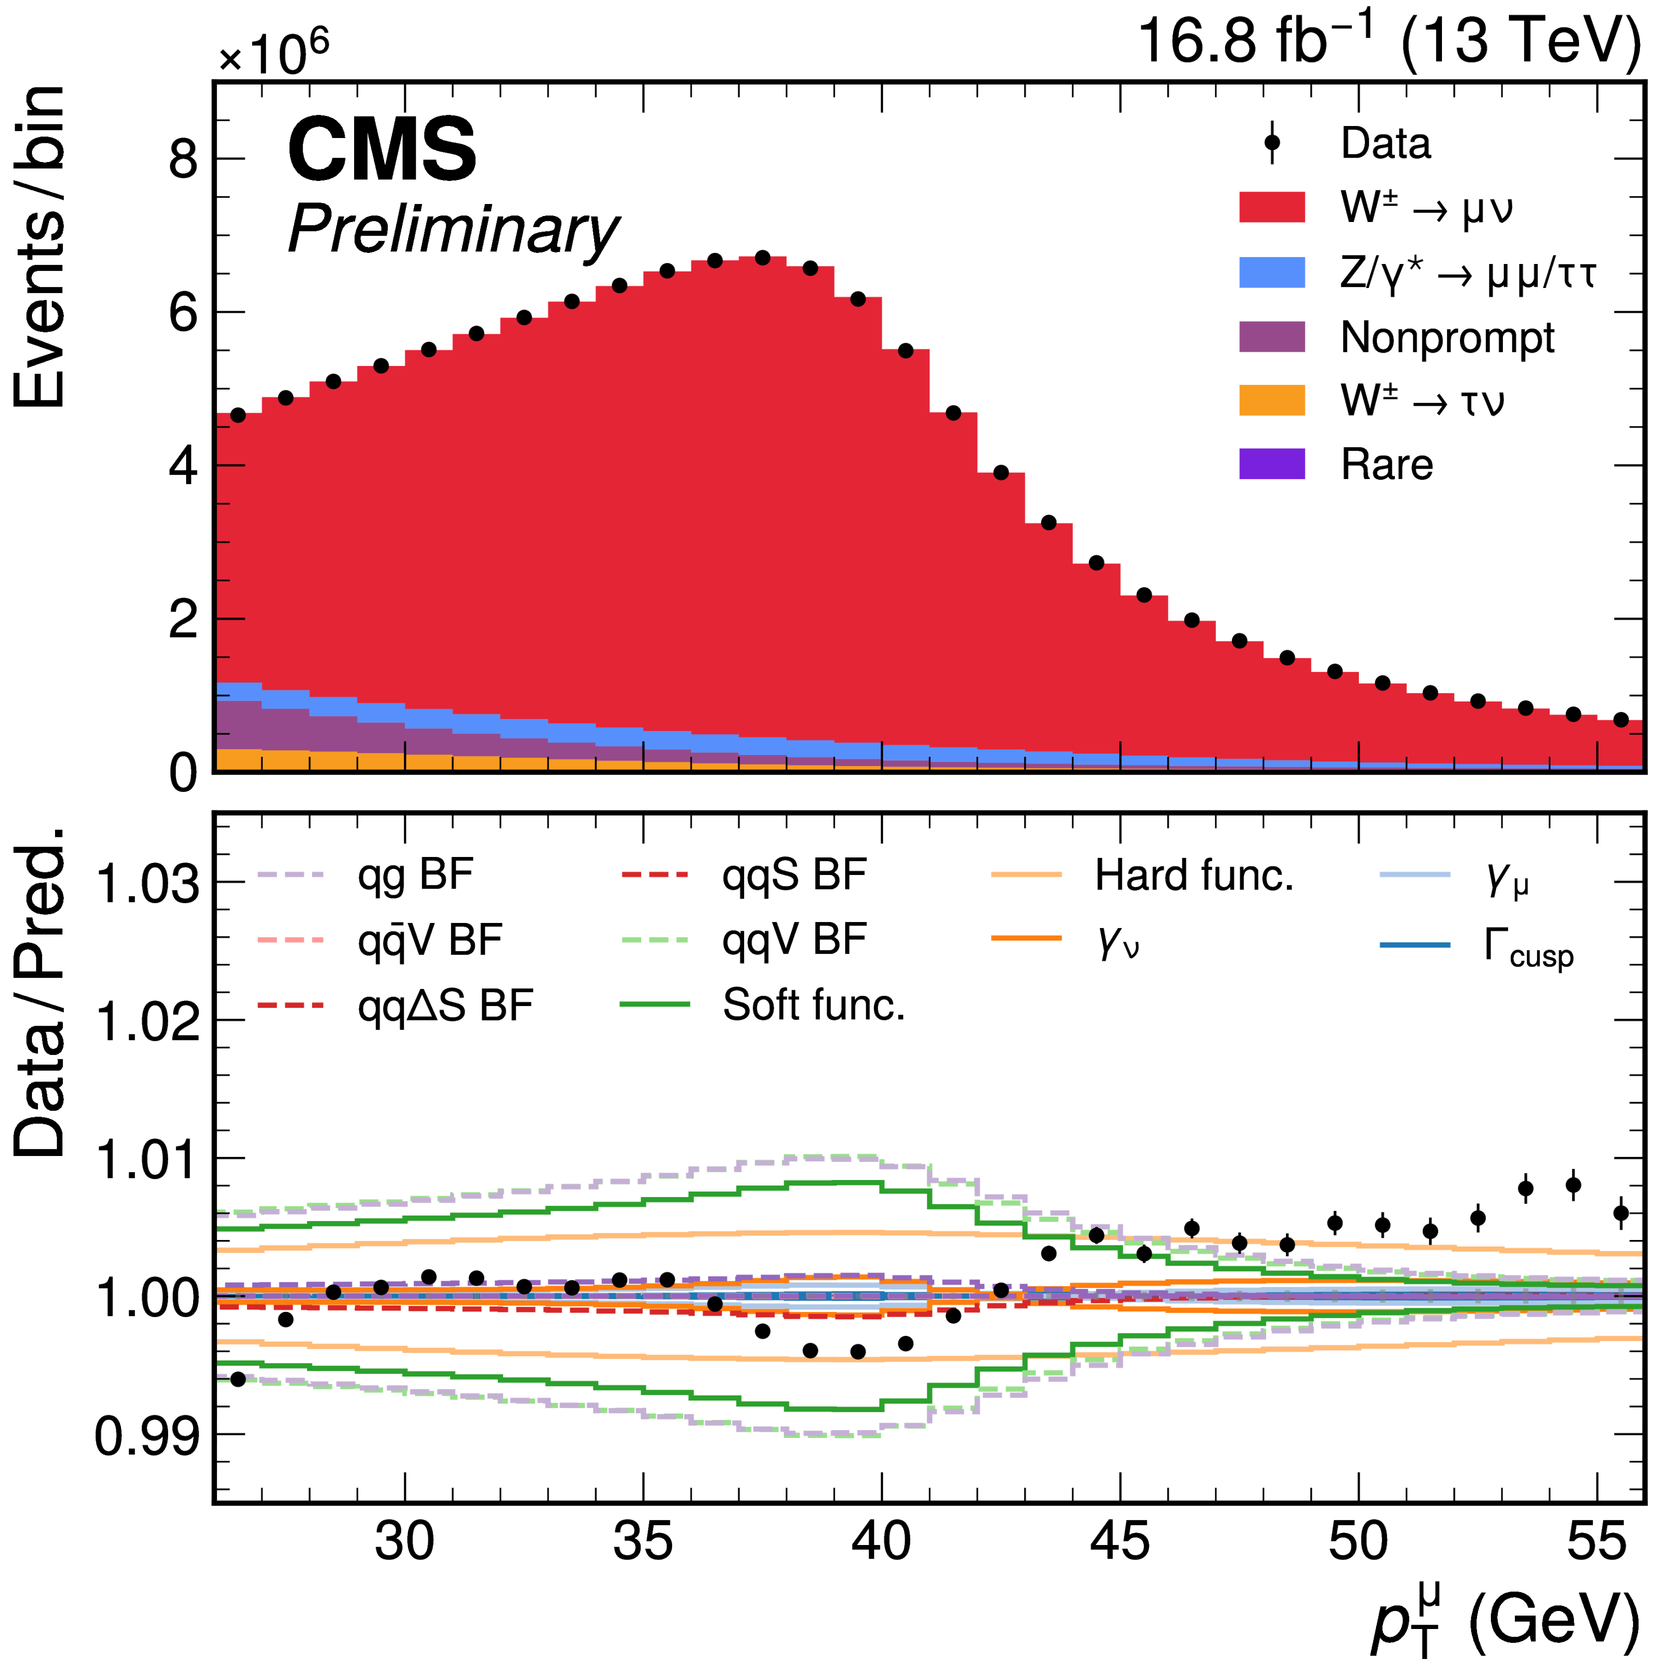




Perturbative uncertainties

- **“Theory nuisance parameters” calculated from SCETlib at N³LL** and propagated through analysis
    - Structure of resummation is known to all orders, many corrections are (unknown) numerical constants
    - Parameterize elements of resummation series, uncertainties directly represent unknown terms
    - Meaningful shape variation **(critical!)** and meaningful constraints from data
        - **Unc. in m_W ~0.5 MeV**

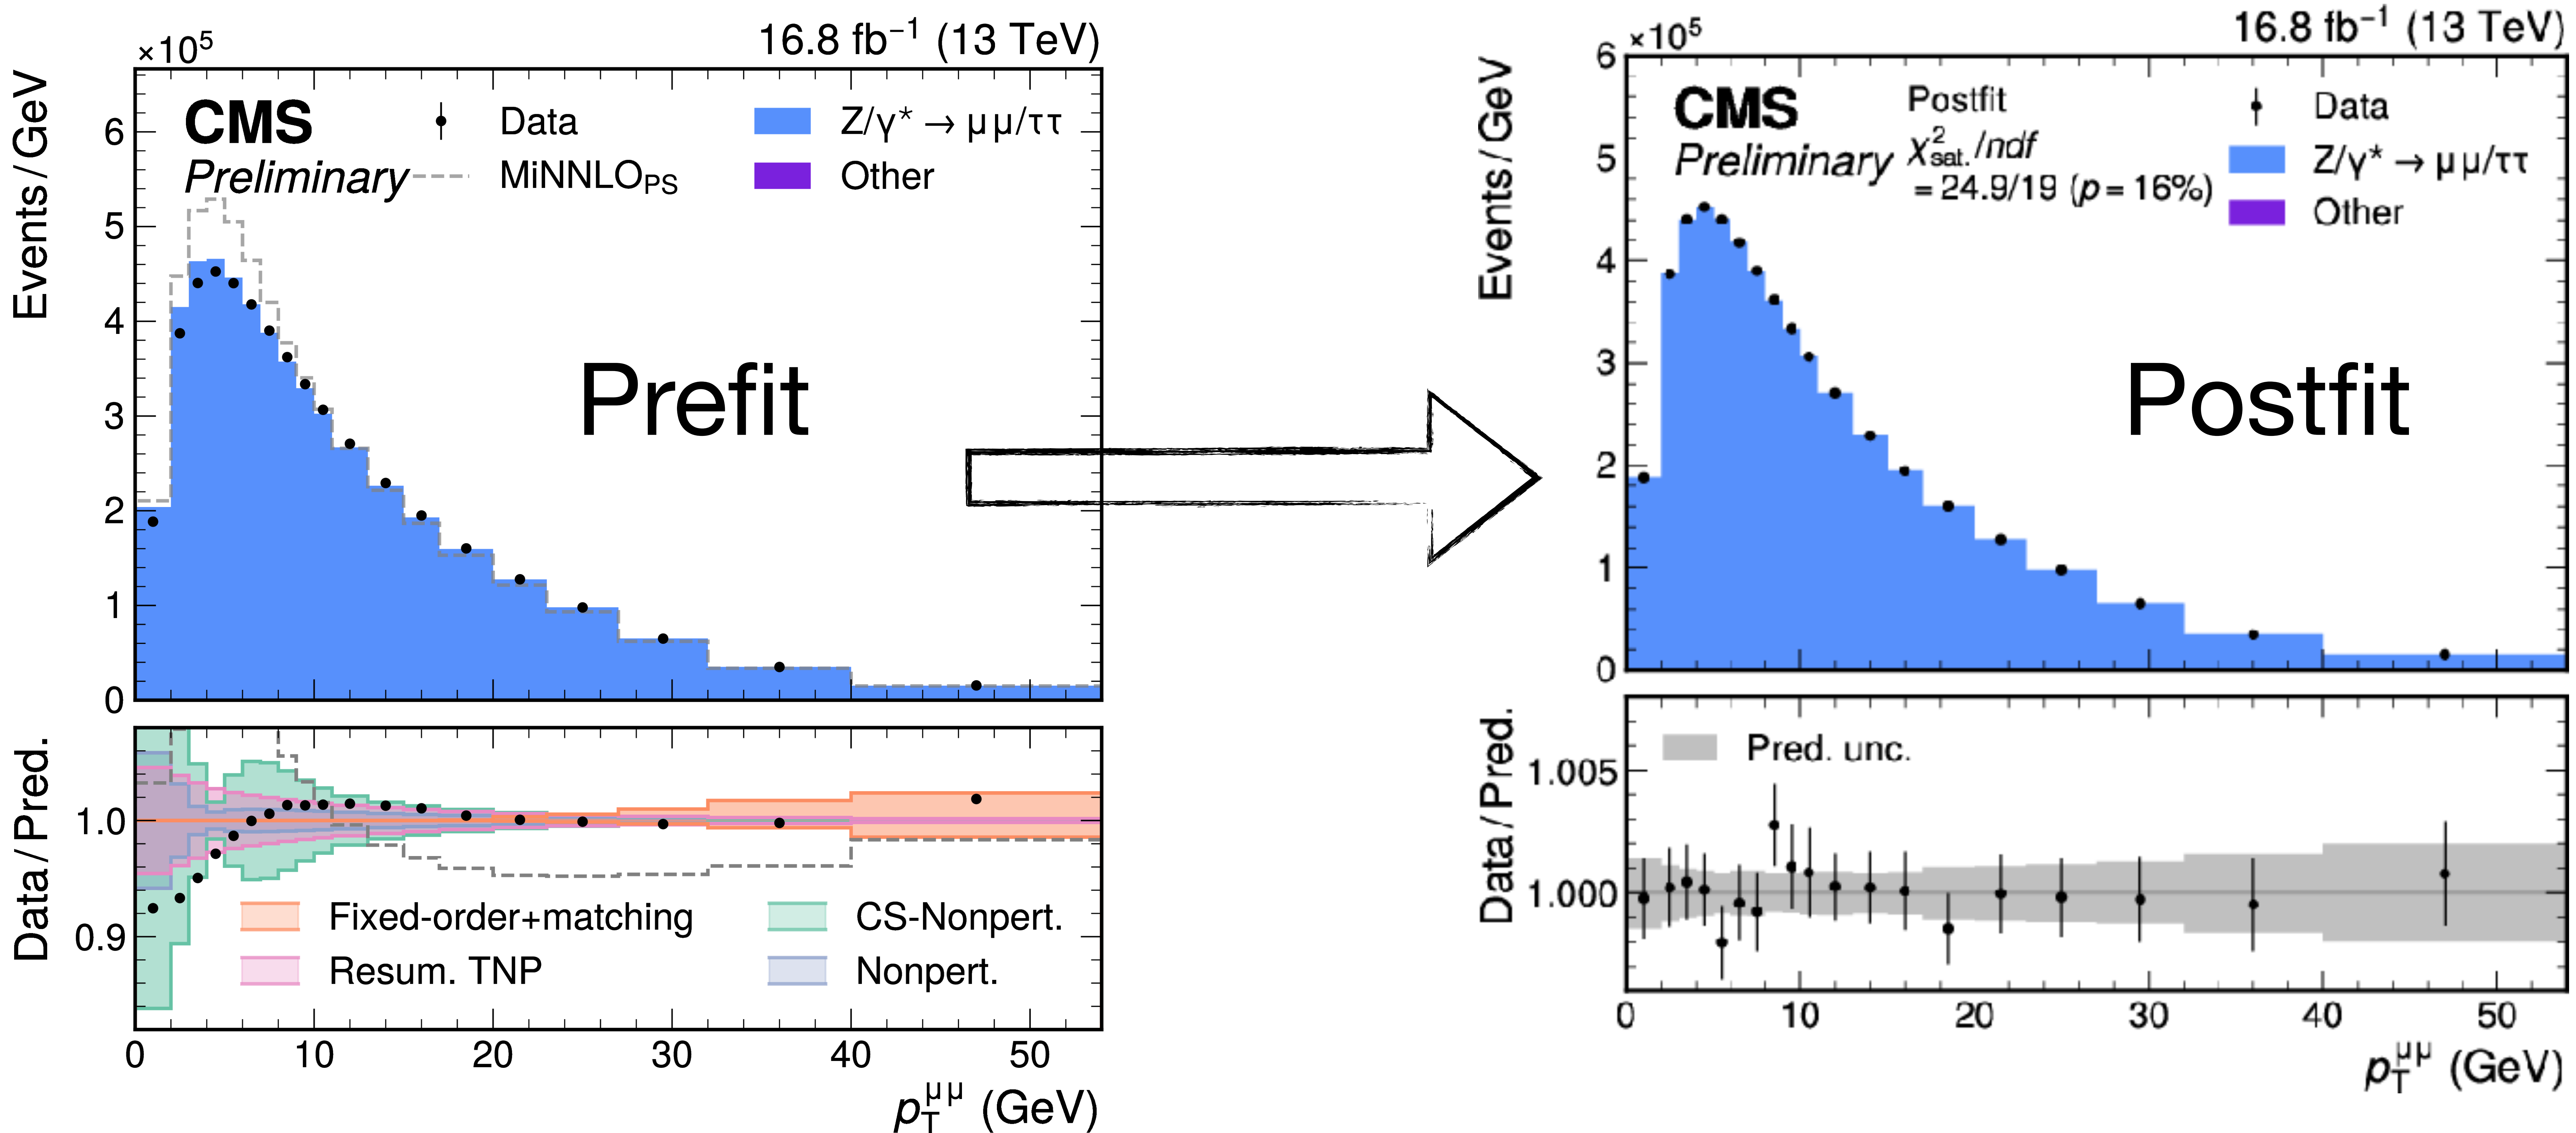




Sufficiency of the theoretical model

- General strategy: **do not tune parameters of the theoretical models**
  - Robust paramterization,uncertainties + data corrections extracted from maximum likelihood fit
- Direct maximum likelihood fit to ($y^{\mu\mu}$, $p_T^{\mu\mu}$) is first test of sufficiency of this approach
  - **P-value of 16%**

➡**Total unc. in m_W 2.0 MeV**



W/Z helicity states and impact on lepton kinematics

- For a given helicity state, **relationship between V = W, Z and decaying leptons is known analytically** (up to small higher-order QED corrections)

$$\frac{\mathrm{d}\sigma}{\mathrm{d}p_{\mathrm{T}}^{2}\,\mathrm{d}m\,\mathrm{d}y\;\mathrm{d}\cos\theta^{*}\,\mathrm{d}\phi^{*}} = \frac{3}{16\pi}\underbrace{\frac{\mathrm{d}\sigma_{\mathrm{UL}}}{\mathrm{d}p_{\mathrm{T}}^{2}\,\mathrm{d}m\,\mathrm{d}y}}_{\text{Kinematics of W/Z}}\left[(1+\cos^{2}\theta^{*}) + \sum_{i=0}^{7}\underbrace{A_i(p_{\mathrm{T}},m,y)}_{\substack{\text{Angular coefficiencts}\\ \text{(Predicted by pQCD)}}}\cdot\underbrace{P_i(\cos\theta^{*},\phi^{*})}_{\substack{\text{Spherical harmonics of}\\ \text{decay angles in CS frame}}}\right]$$

- Modifications of A_i **change relationship between p_T^V and p_T^μ**
  - Estimated at NNLO with MiNNLO, verified consistency with fixed-order NNLO
  - Uncertainty from scale variations, decorrelated across 10 bins of p_T^V
  - ➡**3.3 MeV unc. in mW**

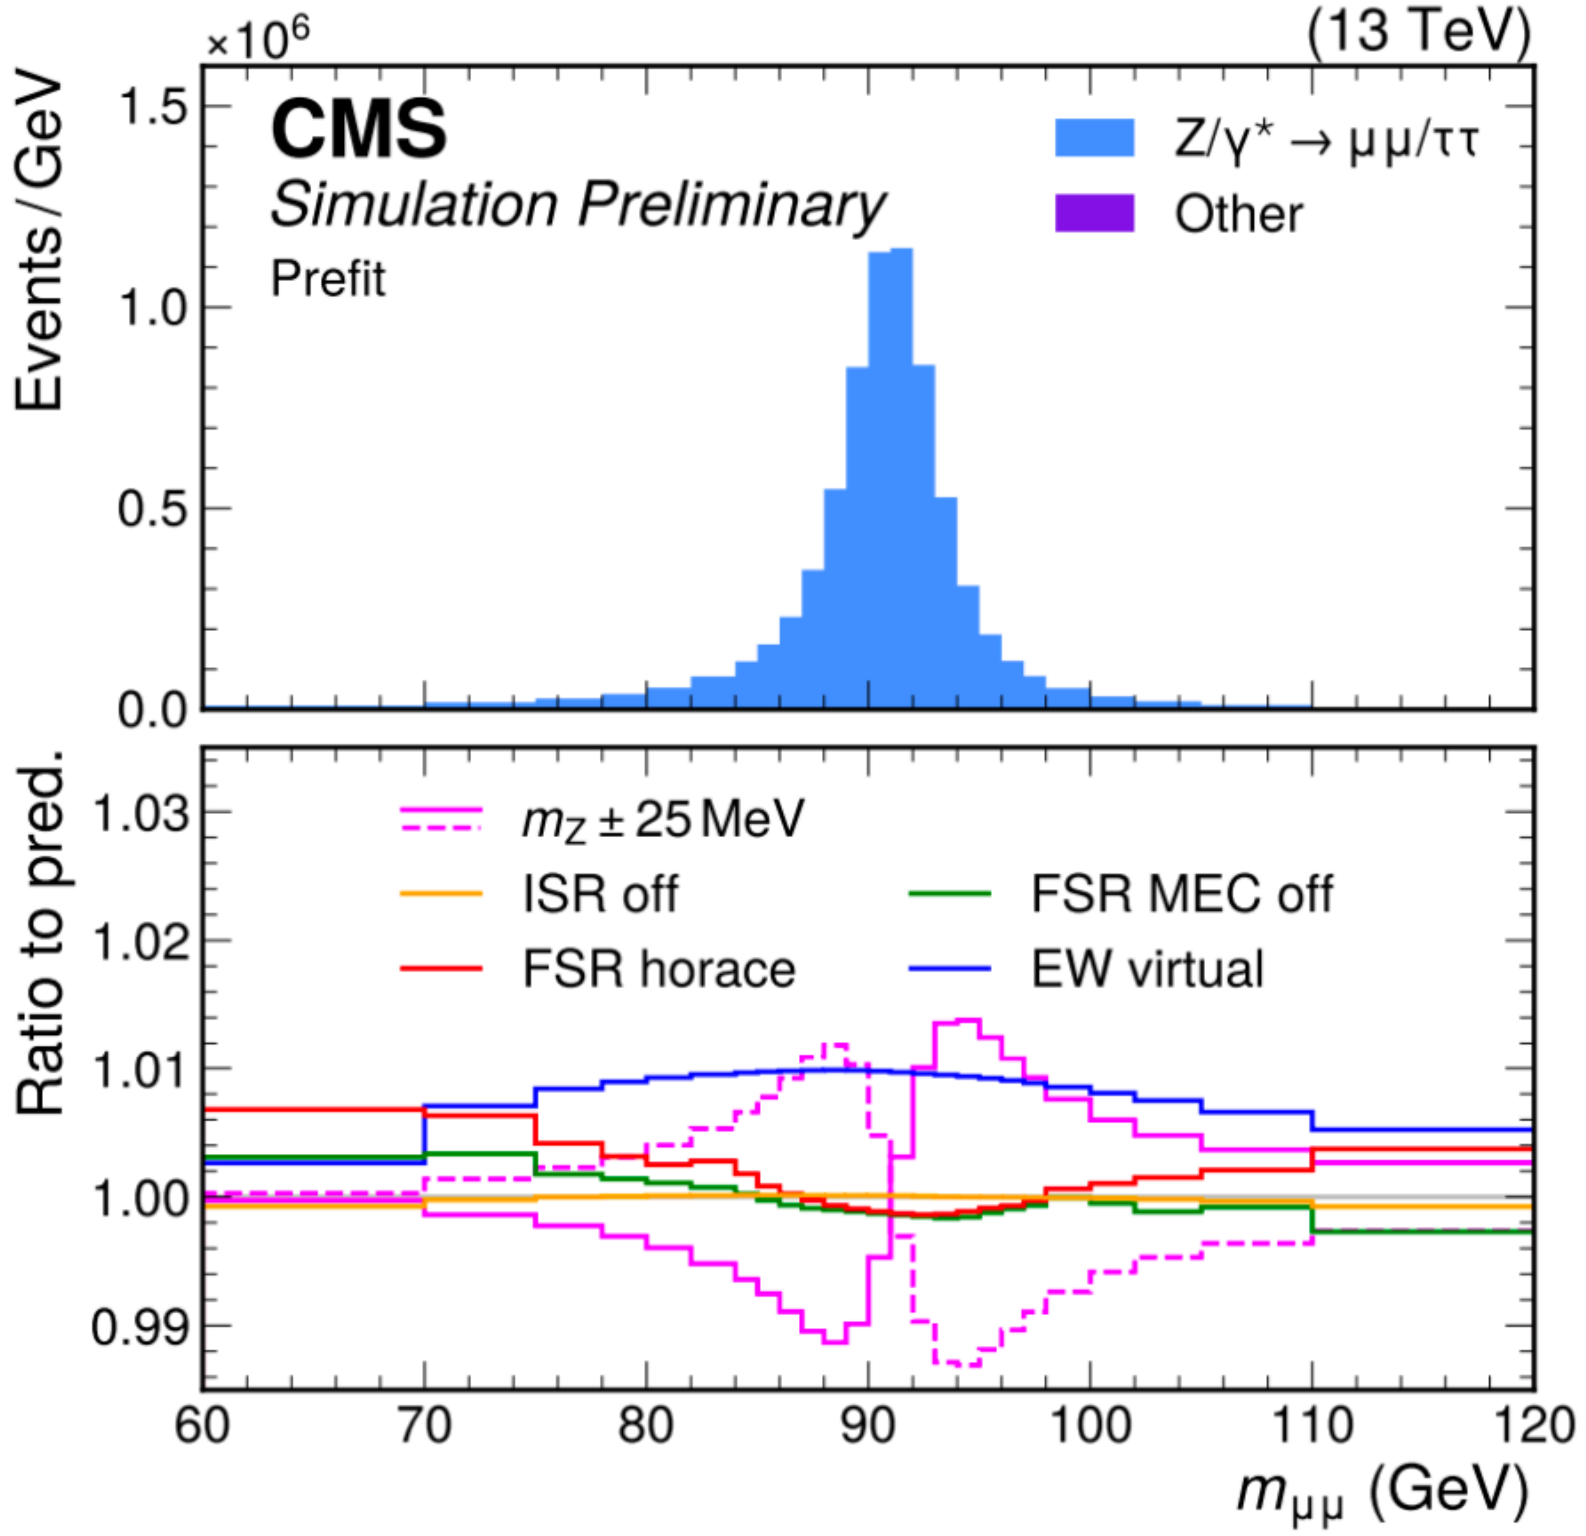
- Exploit this relationship for **alternative theory-reduced measurement (helicity cross-section fit)**
  - Attempt to measure (y^V, p_T^V) templates by dividing (η^μ, p_T^μ) templates by A_i
  - ~600 parameters, binned in (y^V, p_T^V) per A_i, loose constrained around theory
    - Uncertainty in σ_{UL} (σ_4) of 50% (100%), others constrained by envelope of theory unc (e.g., different PDFs)

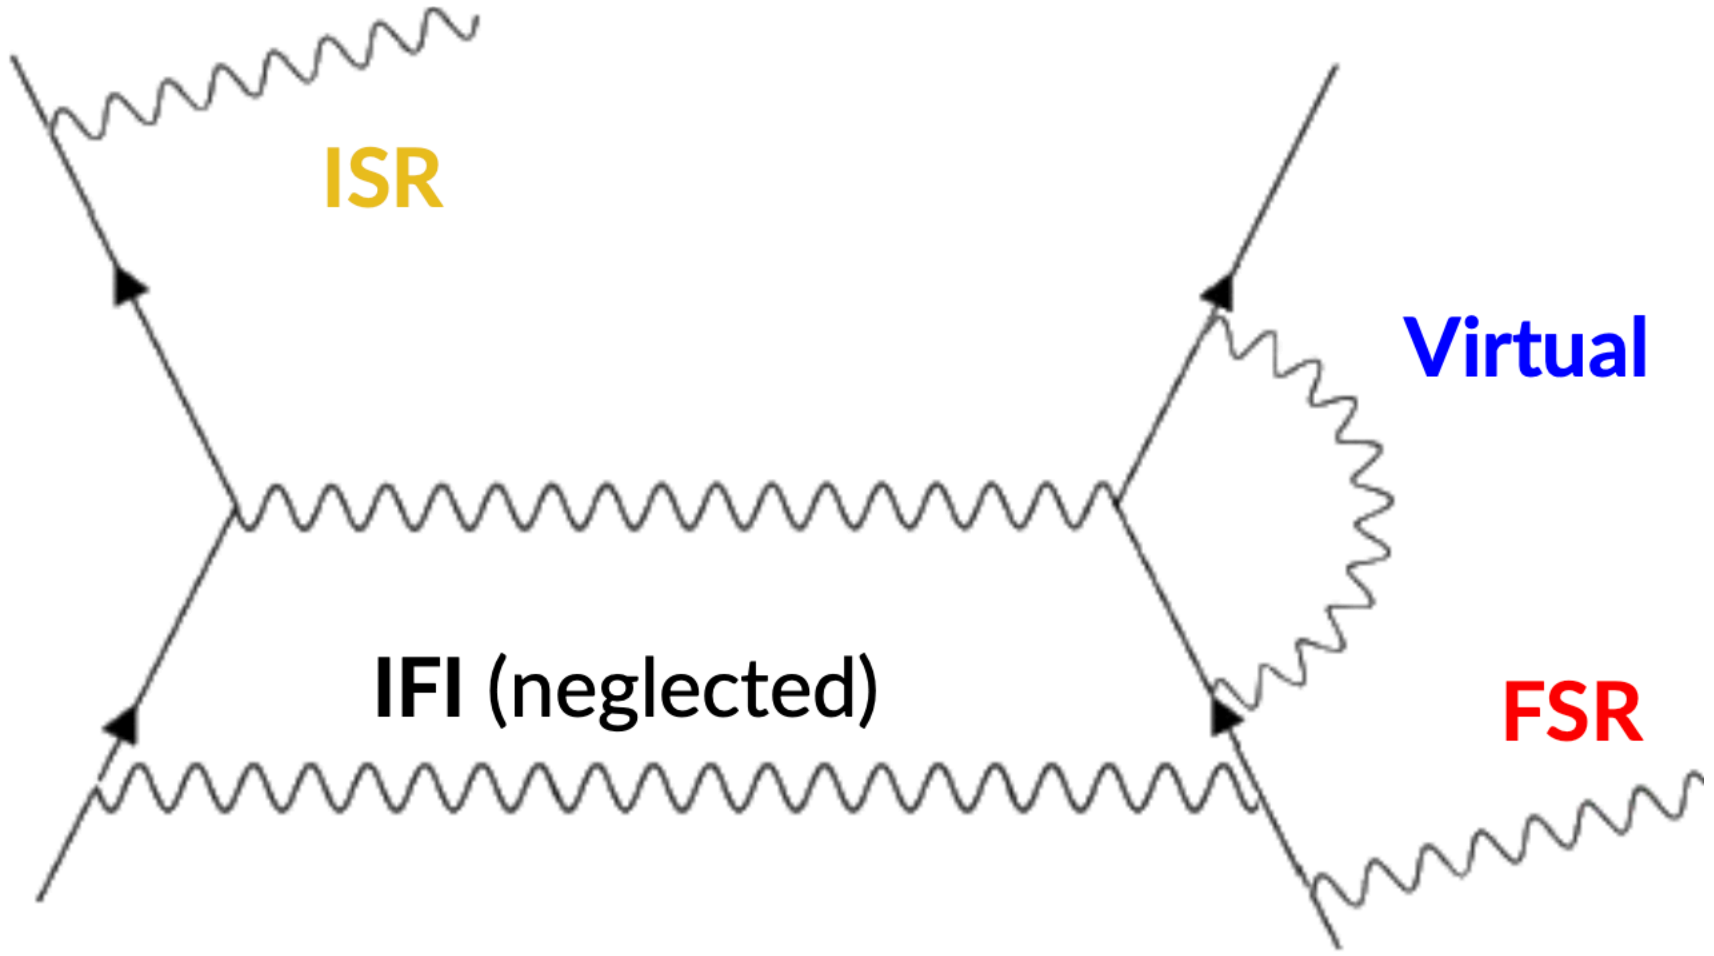
➡Larger stat. uncertainty but reduced theory dependence

Higher-order EW uncertainties

- Main impact of EW corrections captured by photos in nominal simulation
  - Includes QED @leading-log γ→ee/μμ pair production and matrix element corrections (MEC) ~NLO QED

- Impact of higher-order EW evaluated by comparisons of full NLO EW calculation to MiNNLO+photos prediction. Factorized
  - FSR ~ **0.3 MeV in m_W**
    - Horace QED FSR
    - Photos++ MEC off
  - ISR < **0.1 MeV**
    - Switching on/off QED ISR in pythia
  - Virtual ~**1.9 MeV**
    - Z: Powheg NLO+HO EW
    - W: ReneSANCe NLO+HO EW





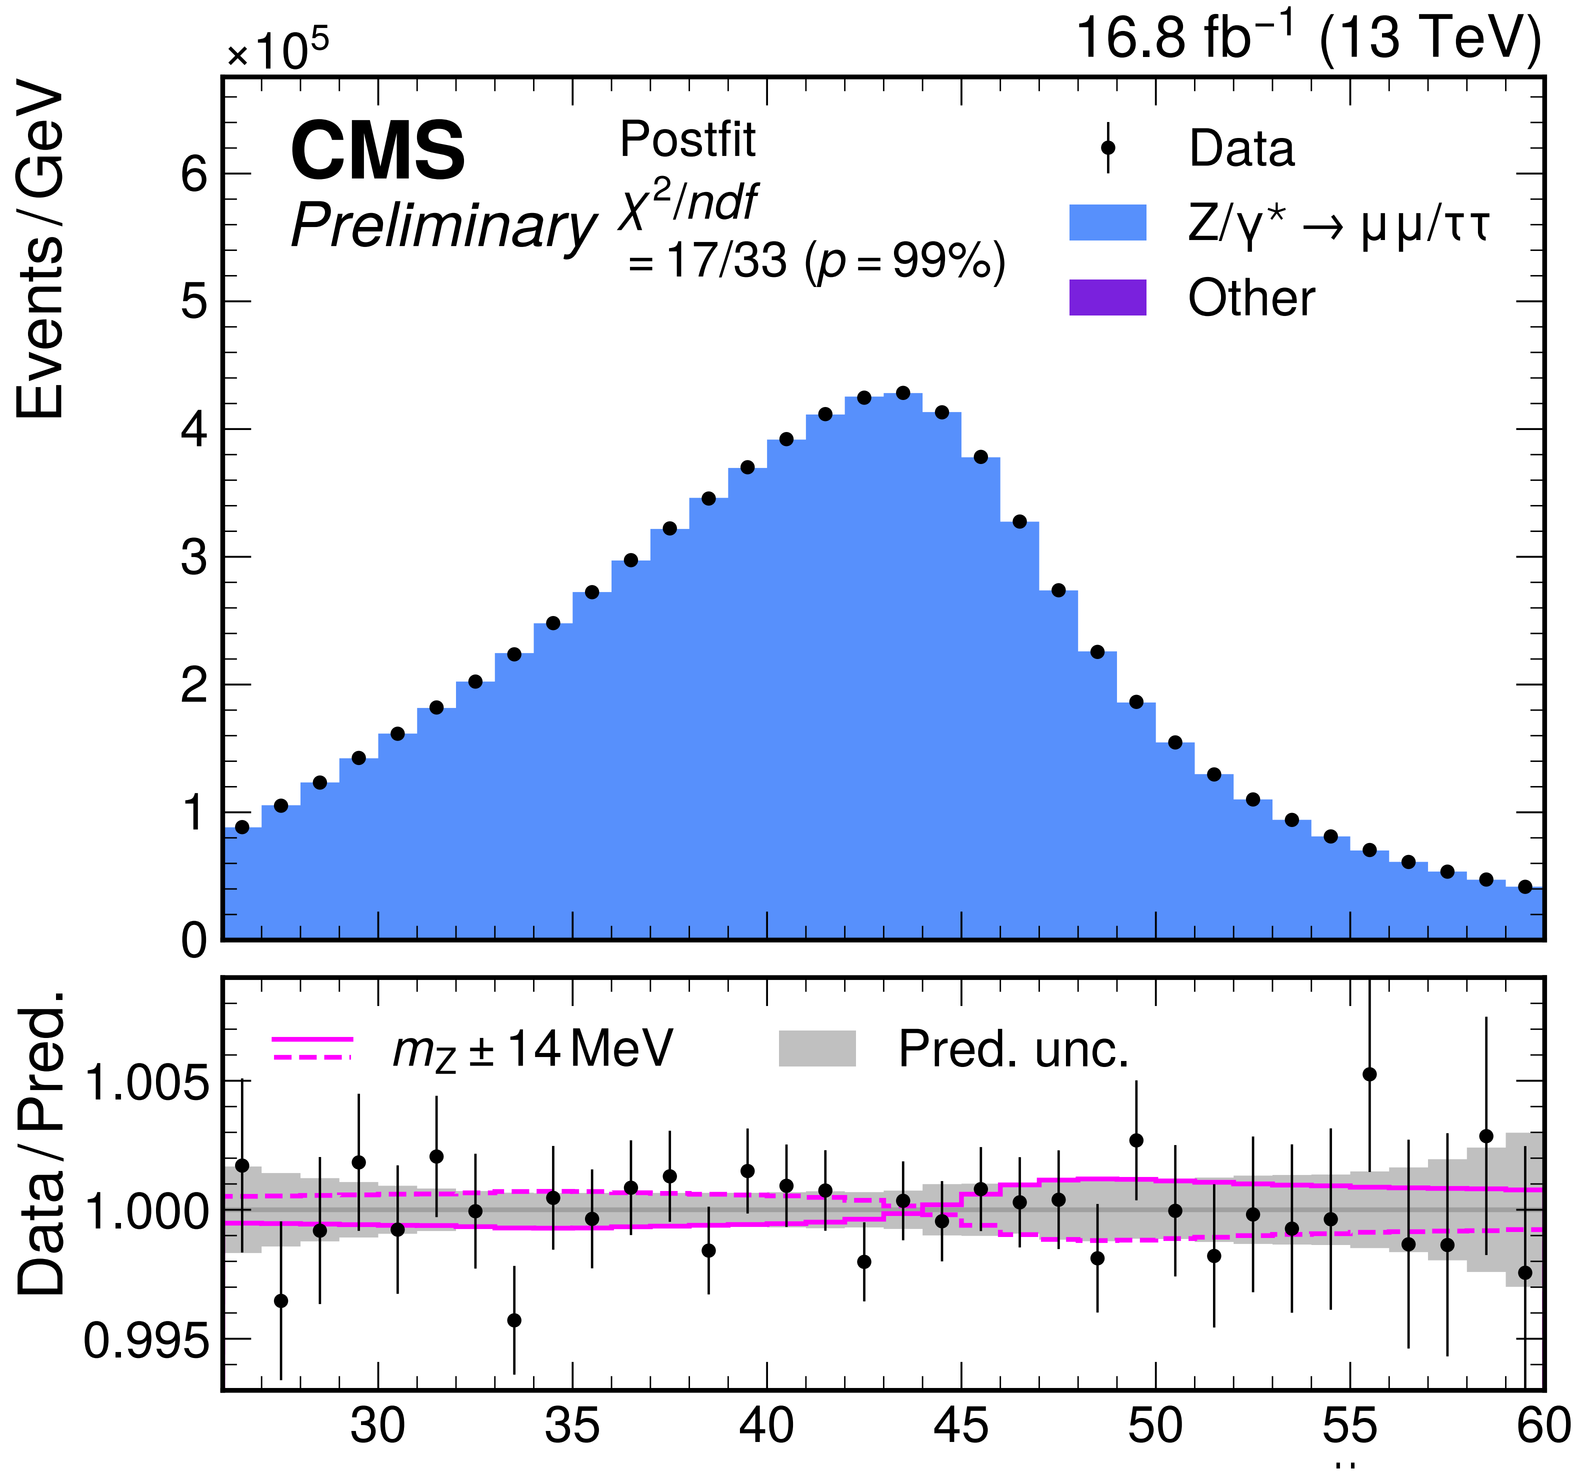
ATLAS: Pythia vs. Photos (6 MeV unc.)
CDF: 2.7 MeV unc. (Horace)

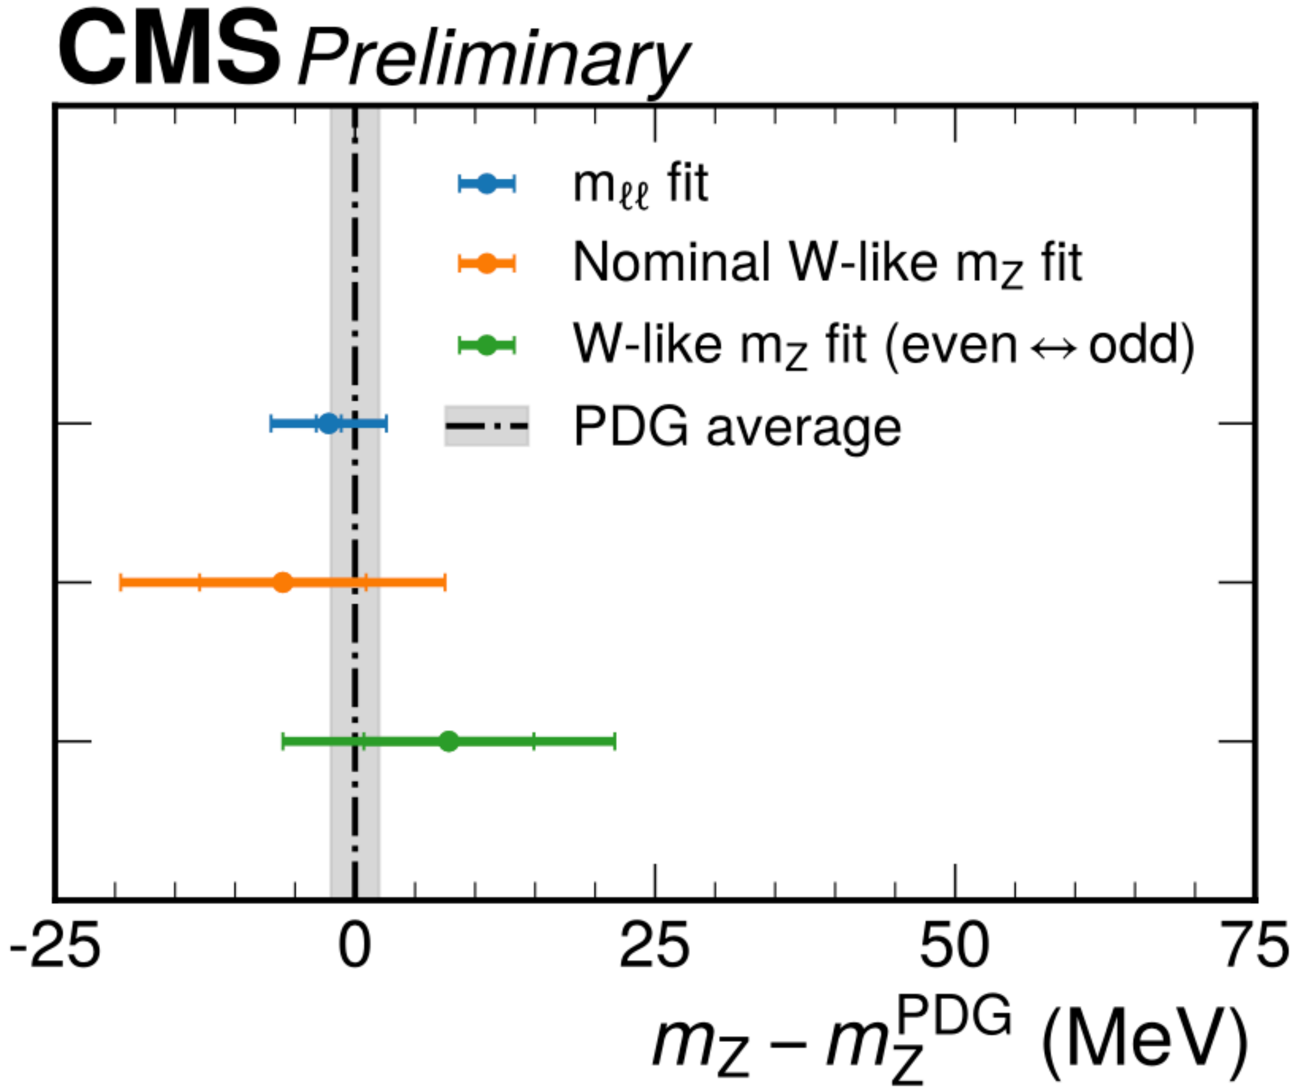
★ Extracting m_Z from fit to (η^μ, p_T^μ)

- W-like measurement of m_Z using approach developed for m_W
  - Split into two data samples to avoid need for evaluating correlations within events
  - Both results highly consistent with PDG (LEP)

$$\boxed{m_Z - m_Z^{\text{PDG}} = -6 \pm 14\,\text{MeV}}$$

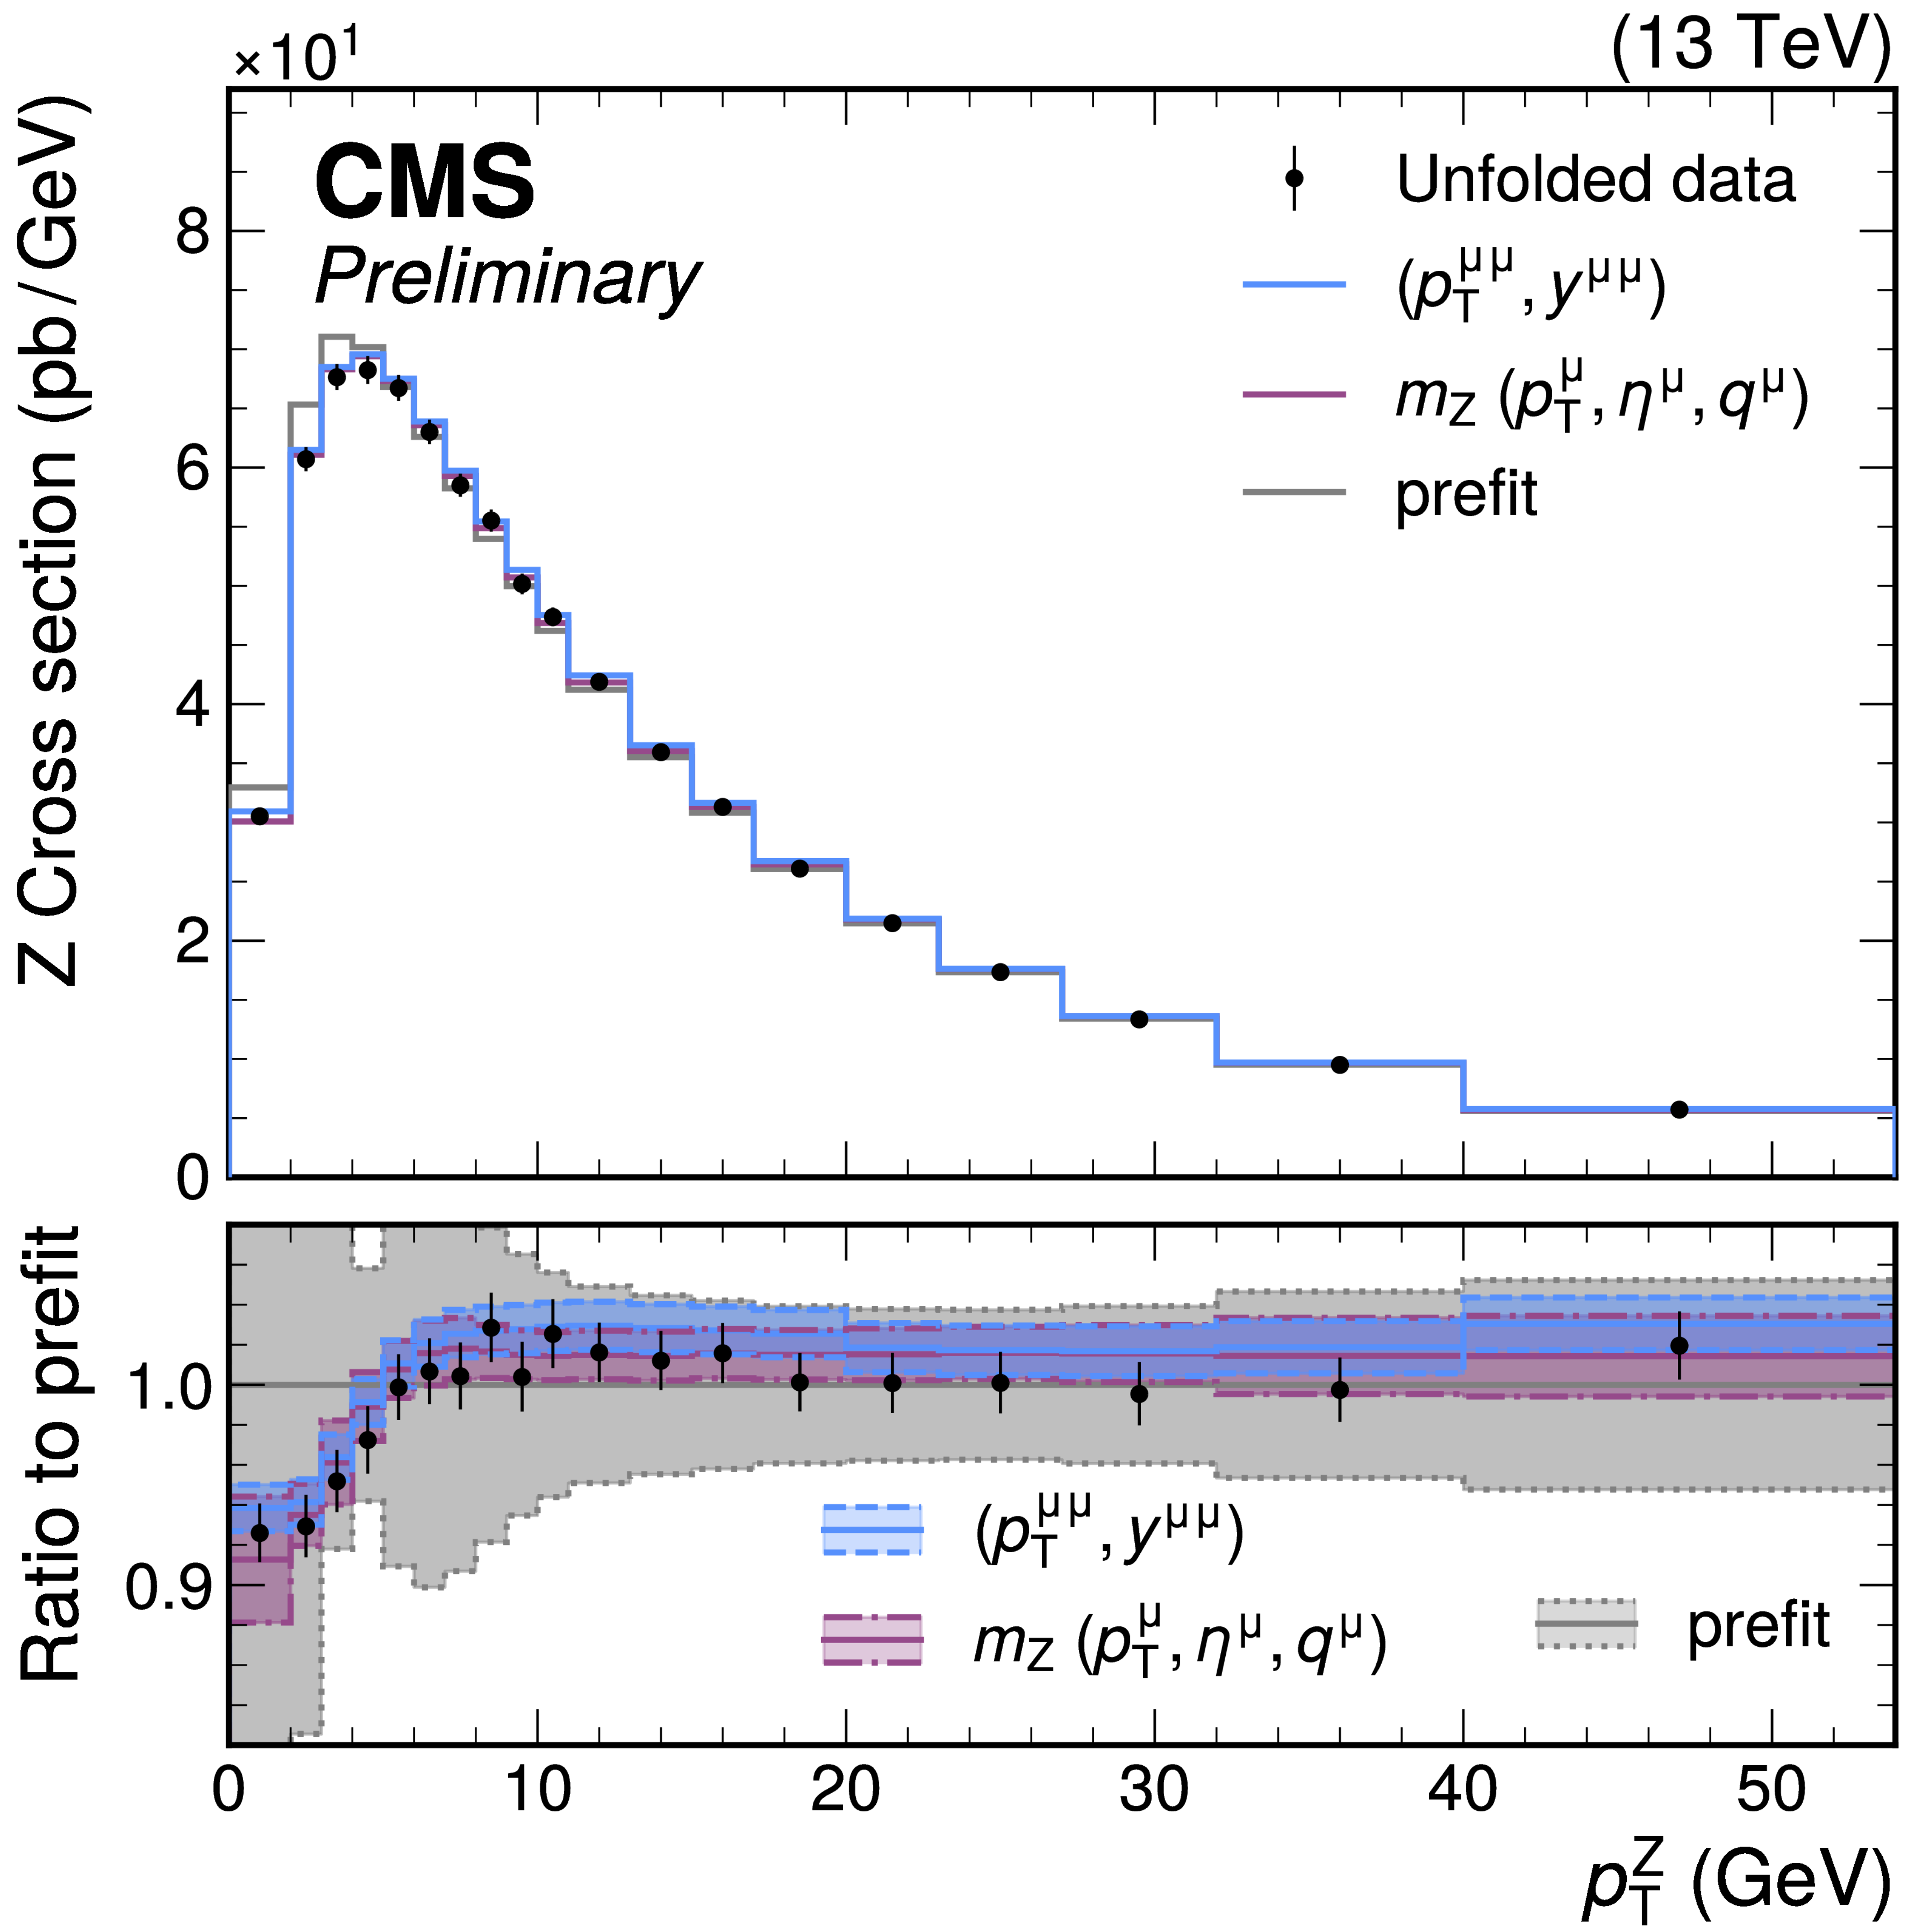
Source of uncertainty	Impact (MeV) Nominal	Impact (MeV) Global
Muon momentum scale	5.6	5.3
Muon reco. efficiency	3.8	3.0
W and Z angular coeffs.	4.9	4.5
Higher-order EW	2.2	2.2
p_T^V modeling	1.7	1.0
PDF	2.4	1.9
Integrated luminosity	0.3	0.2
MC sample size	2.5	3.6
Data sample size	6.9	10.1
Total uncertainty	13.5	13.5





Validation of the theoretical model

- Propagate postfit pulls and constraints of theory uncertainties to generator-level distributions
  - In situ corrections from data
- Compare
  - **Unfolded $p_T^{\mu\mu}$ data**
  - Direct fit to $p_T^{\mu\mu}$
  - W-like (η^μ, p_T^μ) fit
  - Strong and consistent constraints between direct fit to and $p_T^{\mu\mu}$ to p_T^μ

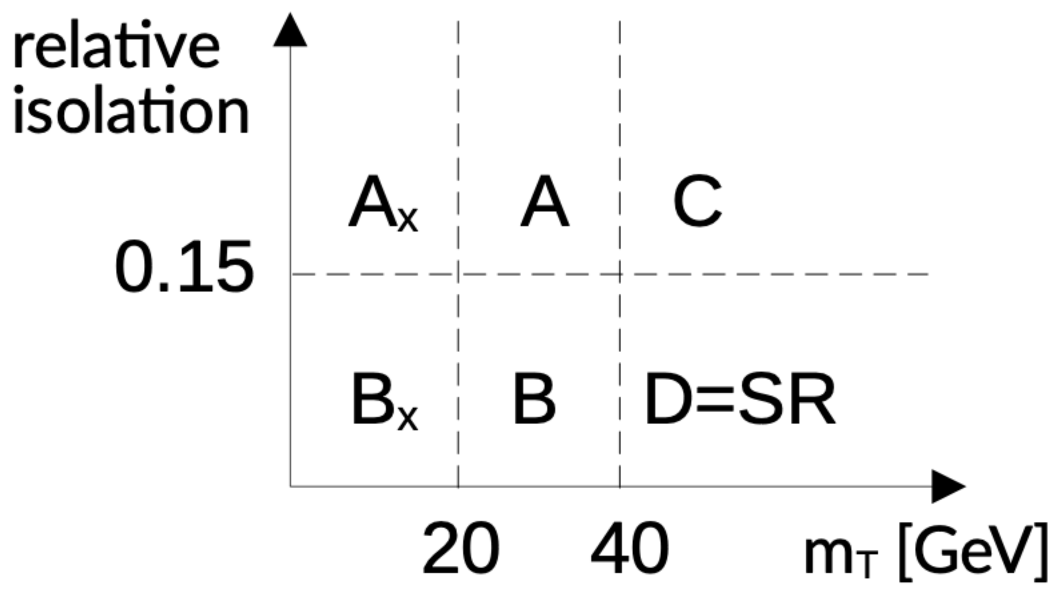


- (η^μ, p_T^μ) distribution able to simultaneously correct $p_T^{\mu\mu}$ and extract m_Z without bias

➡**Justifies performing m_W measurement without corrections from $p_T^{\mu\mu}$**

Nonprompt background estimation

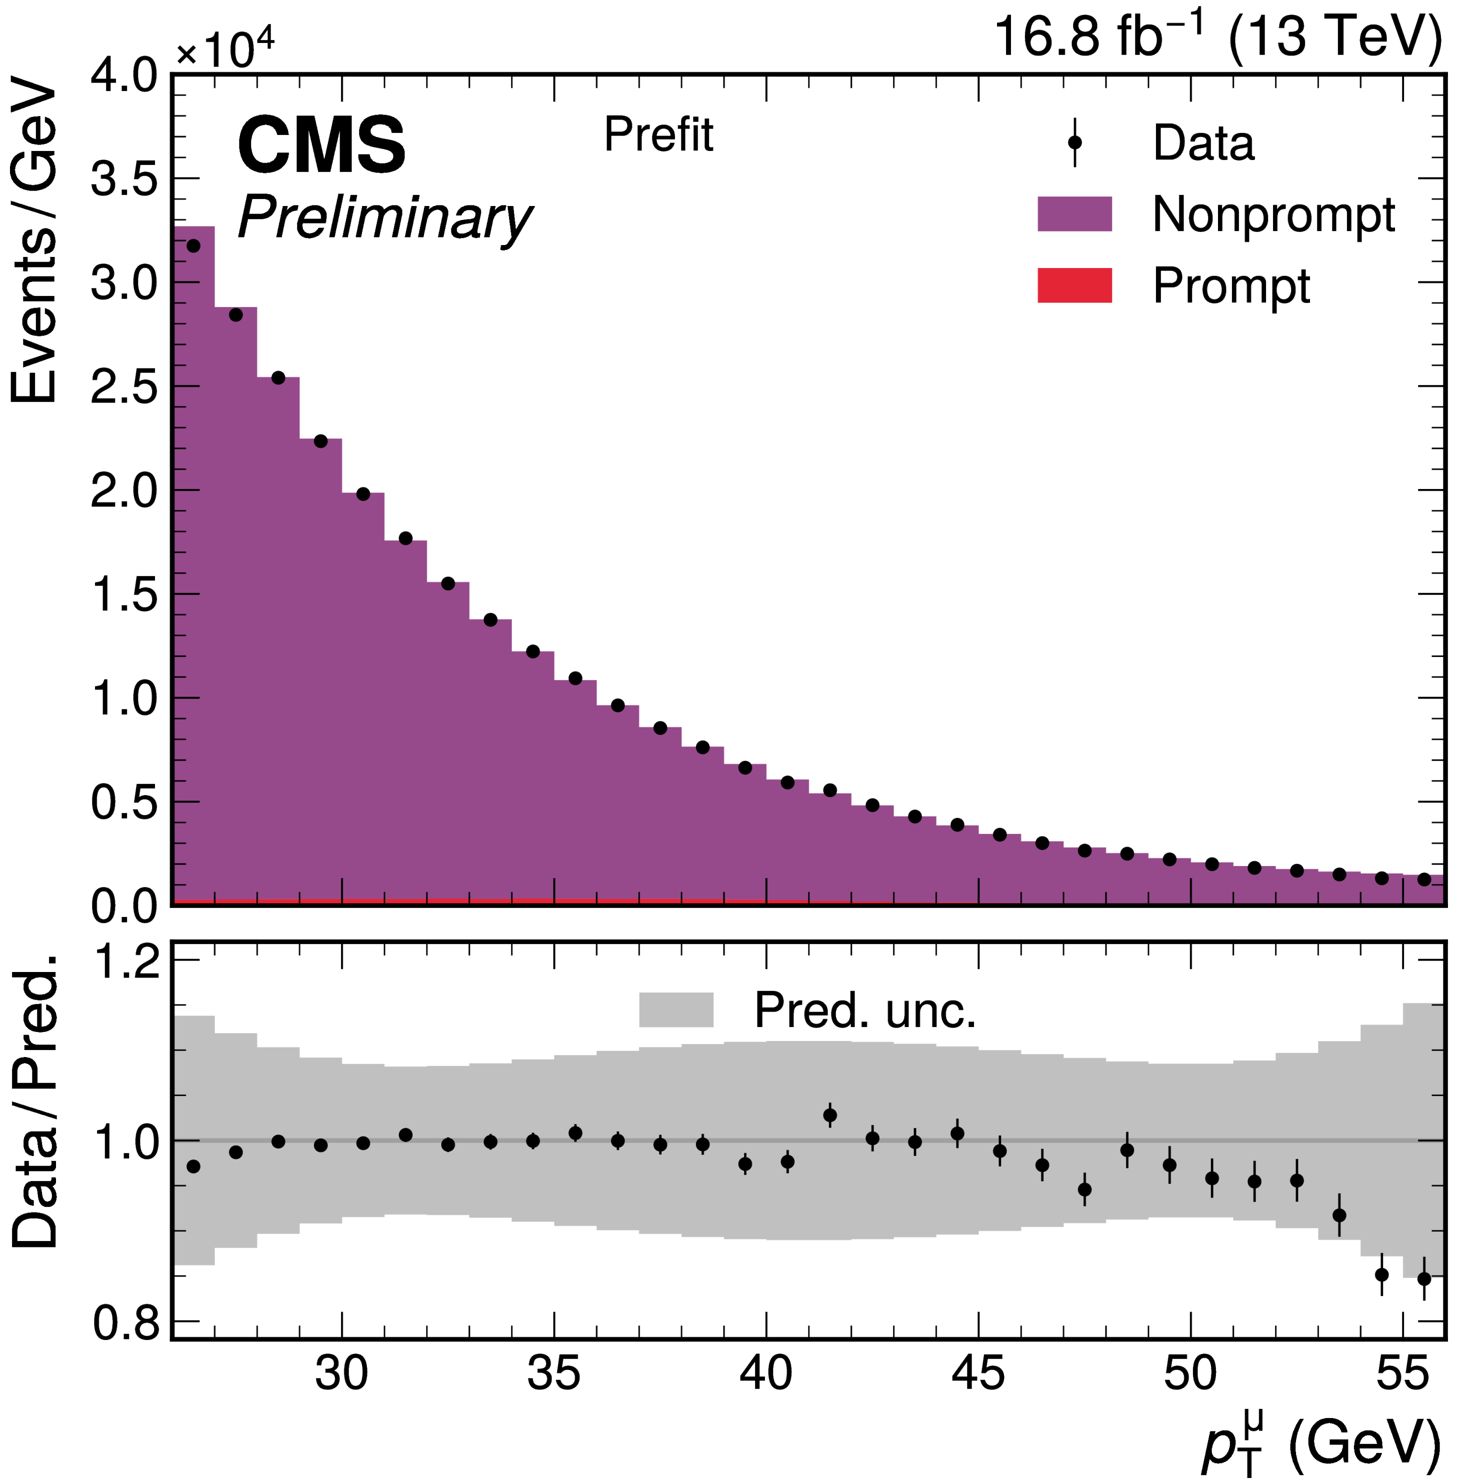
- Data driven estimate with “extended ABCD method”
  - 6 regions of isolation/m_T to correct for correlations
  - Smoothing to reduce stat. fluctuations
  - **3.2 MeV unc. in m_W**
- Full **uncertainties of prompt subtraction propagated through analysis**
  - Dedicated efficiency measurement for iso-failing muons
  - Prompt uncertainty in MC propagated through non-signal regions

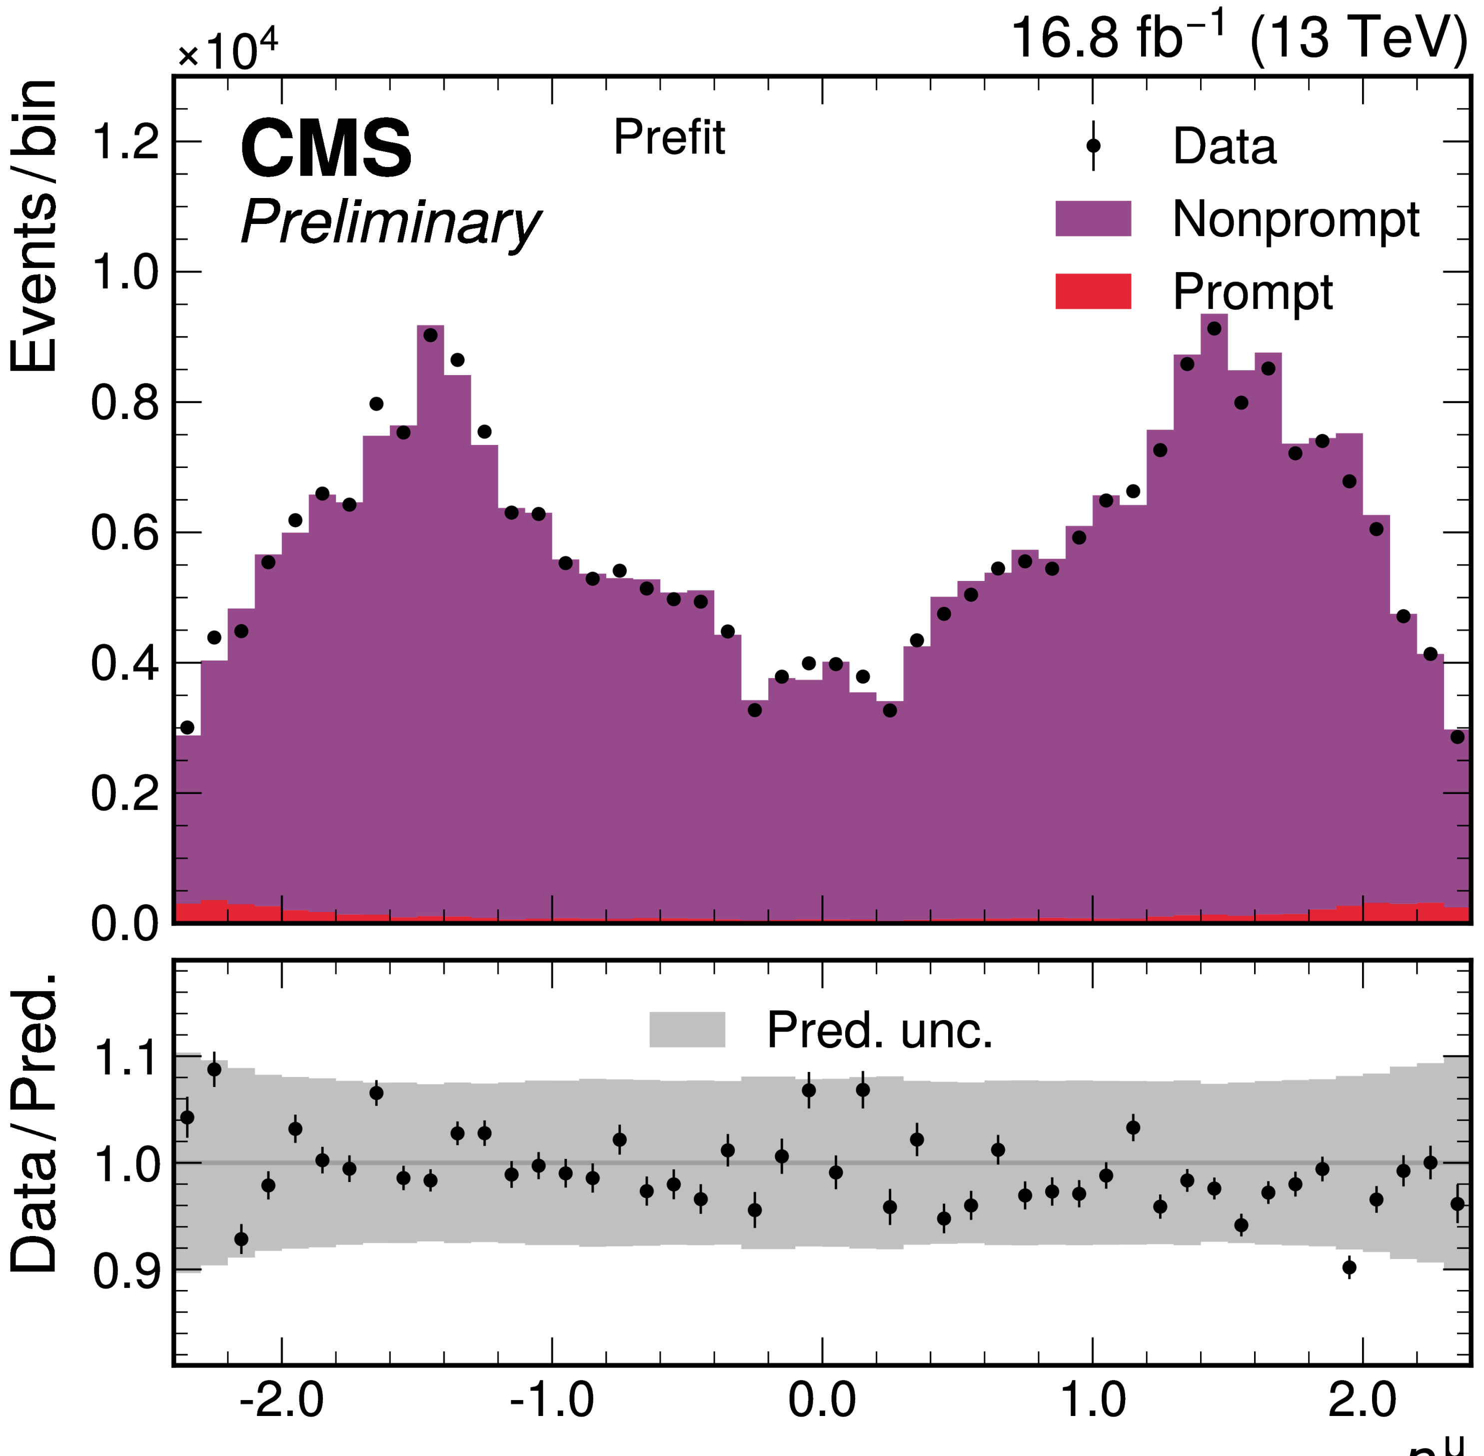


$$D = C \cdot \underbrace{\frac{A_x B^2}{B_x A^2}}_{\text{fakerate}}$$

- Primarily heavy flavour decays to leptons in jets

➡Validated in secondary vertex control region

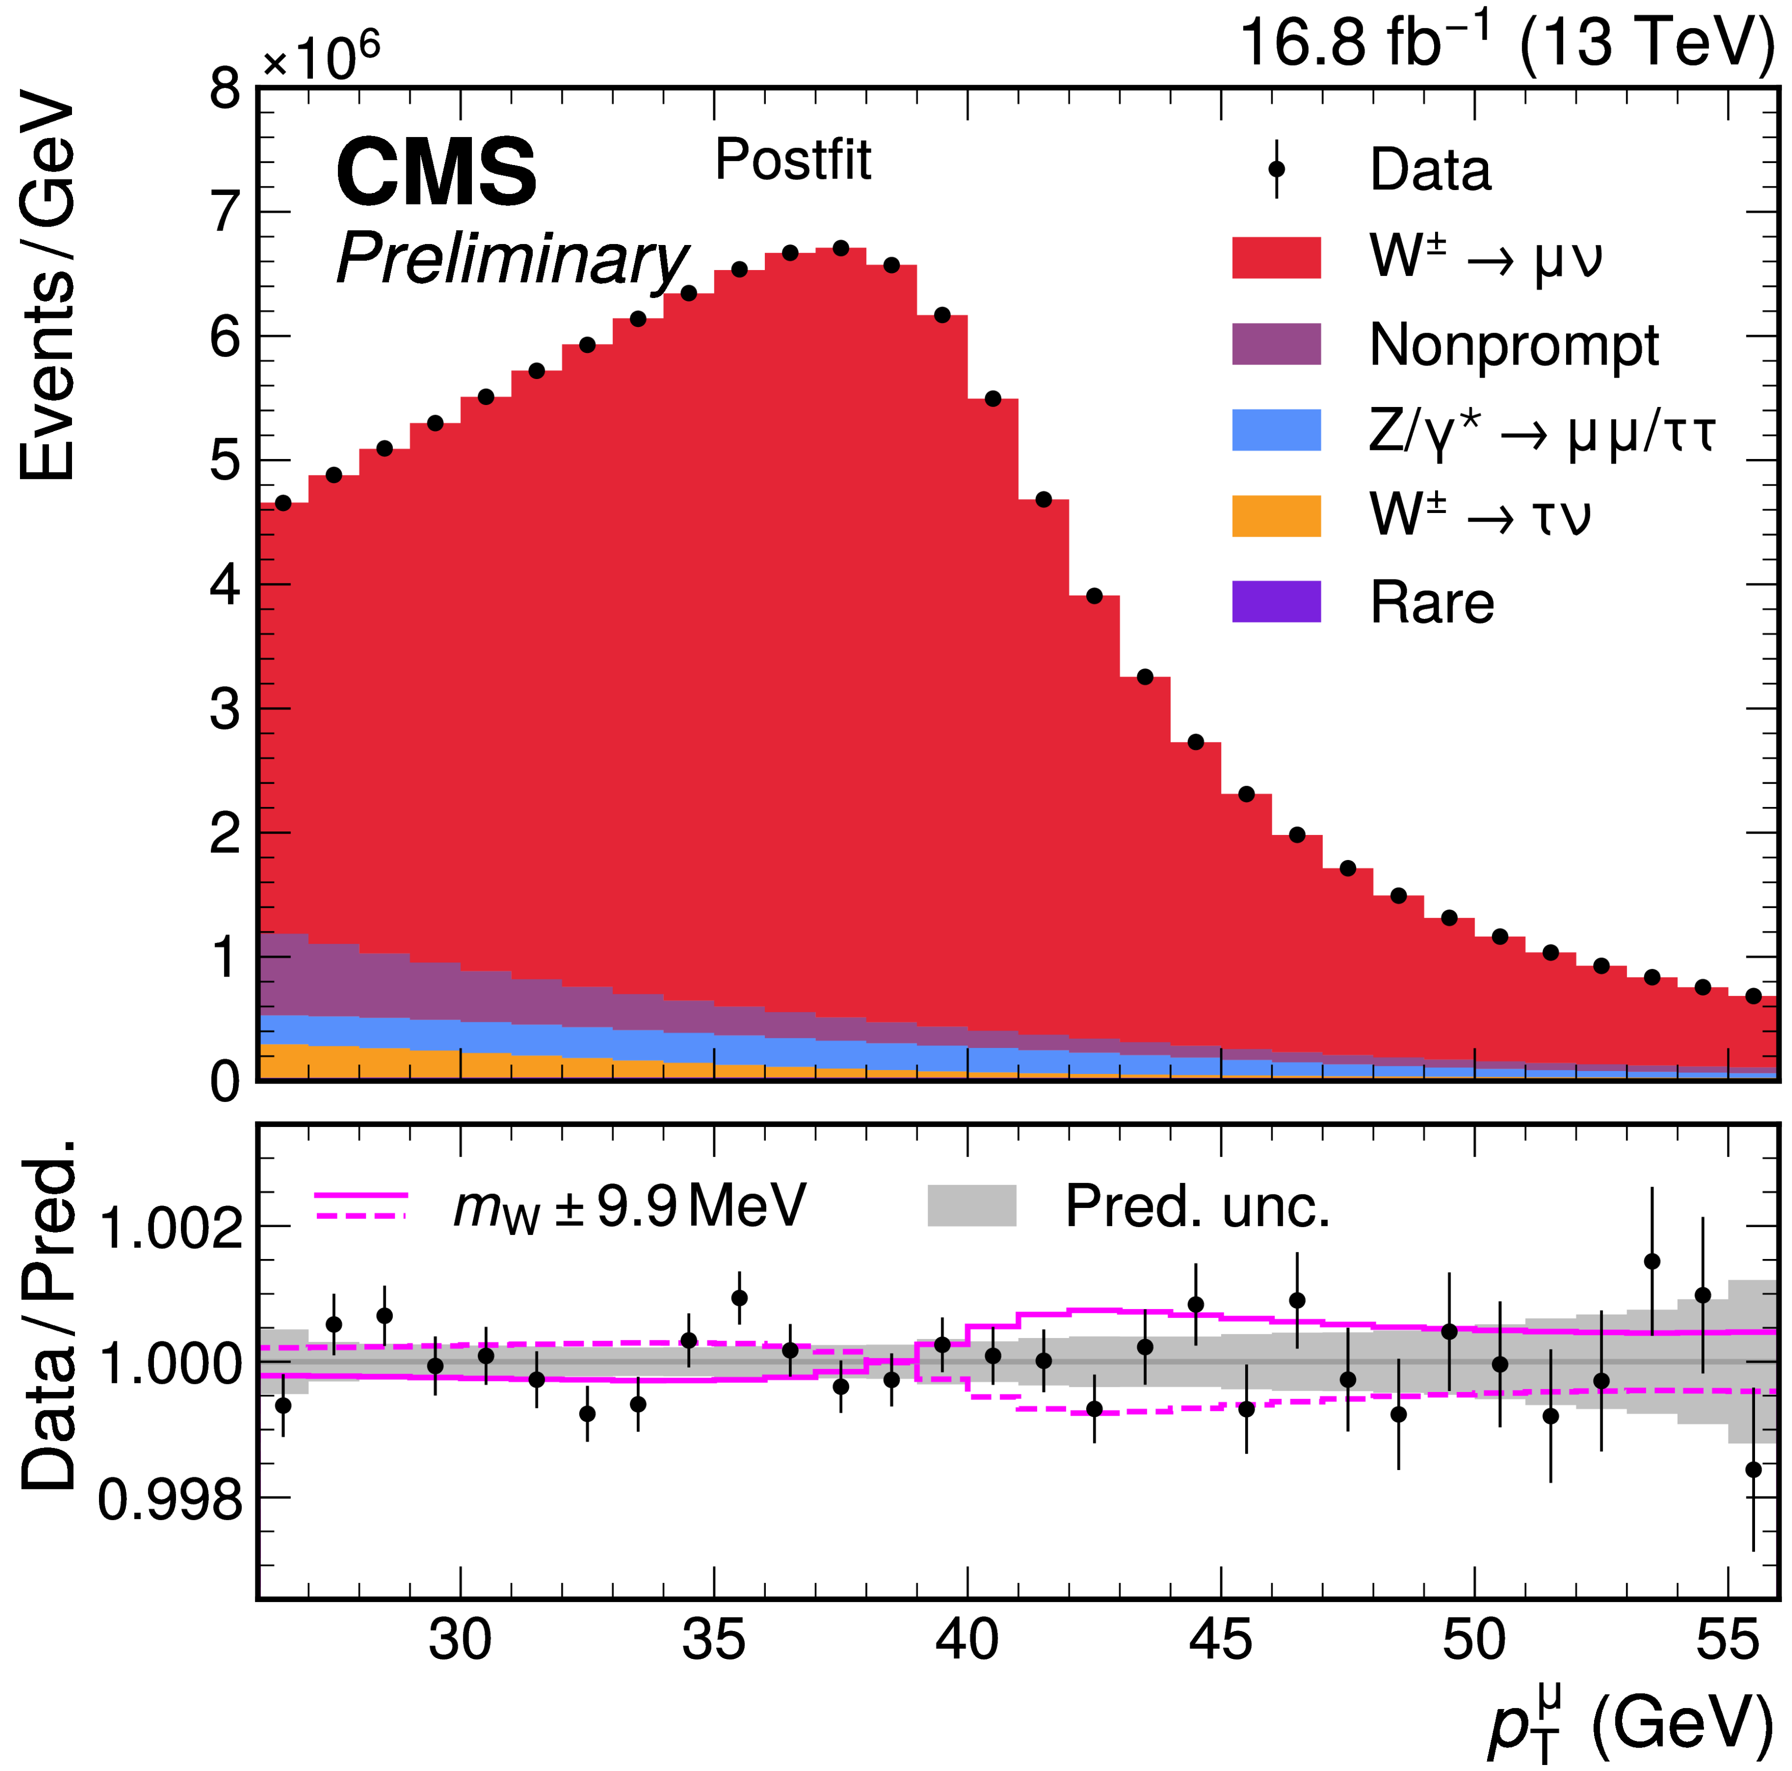


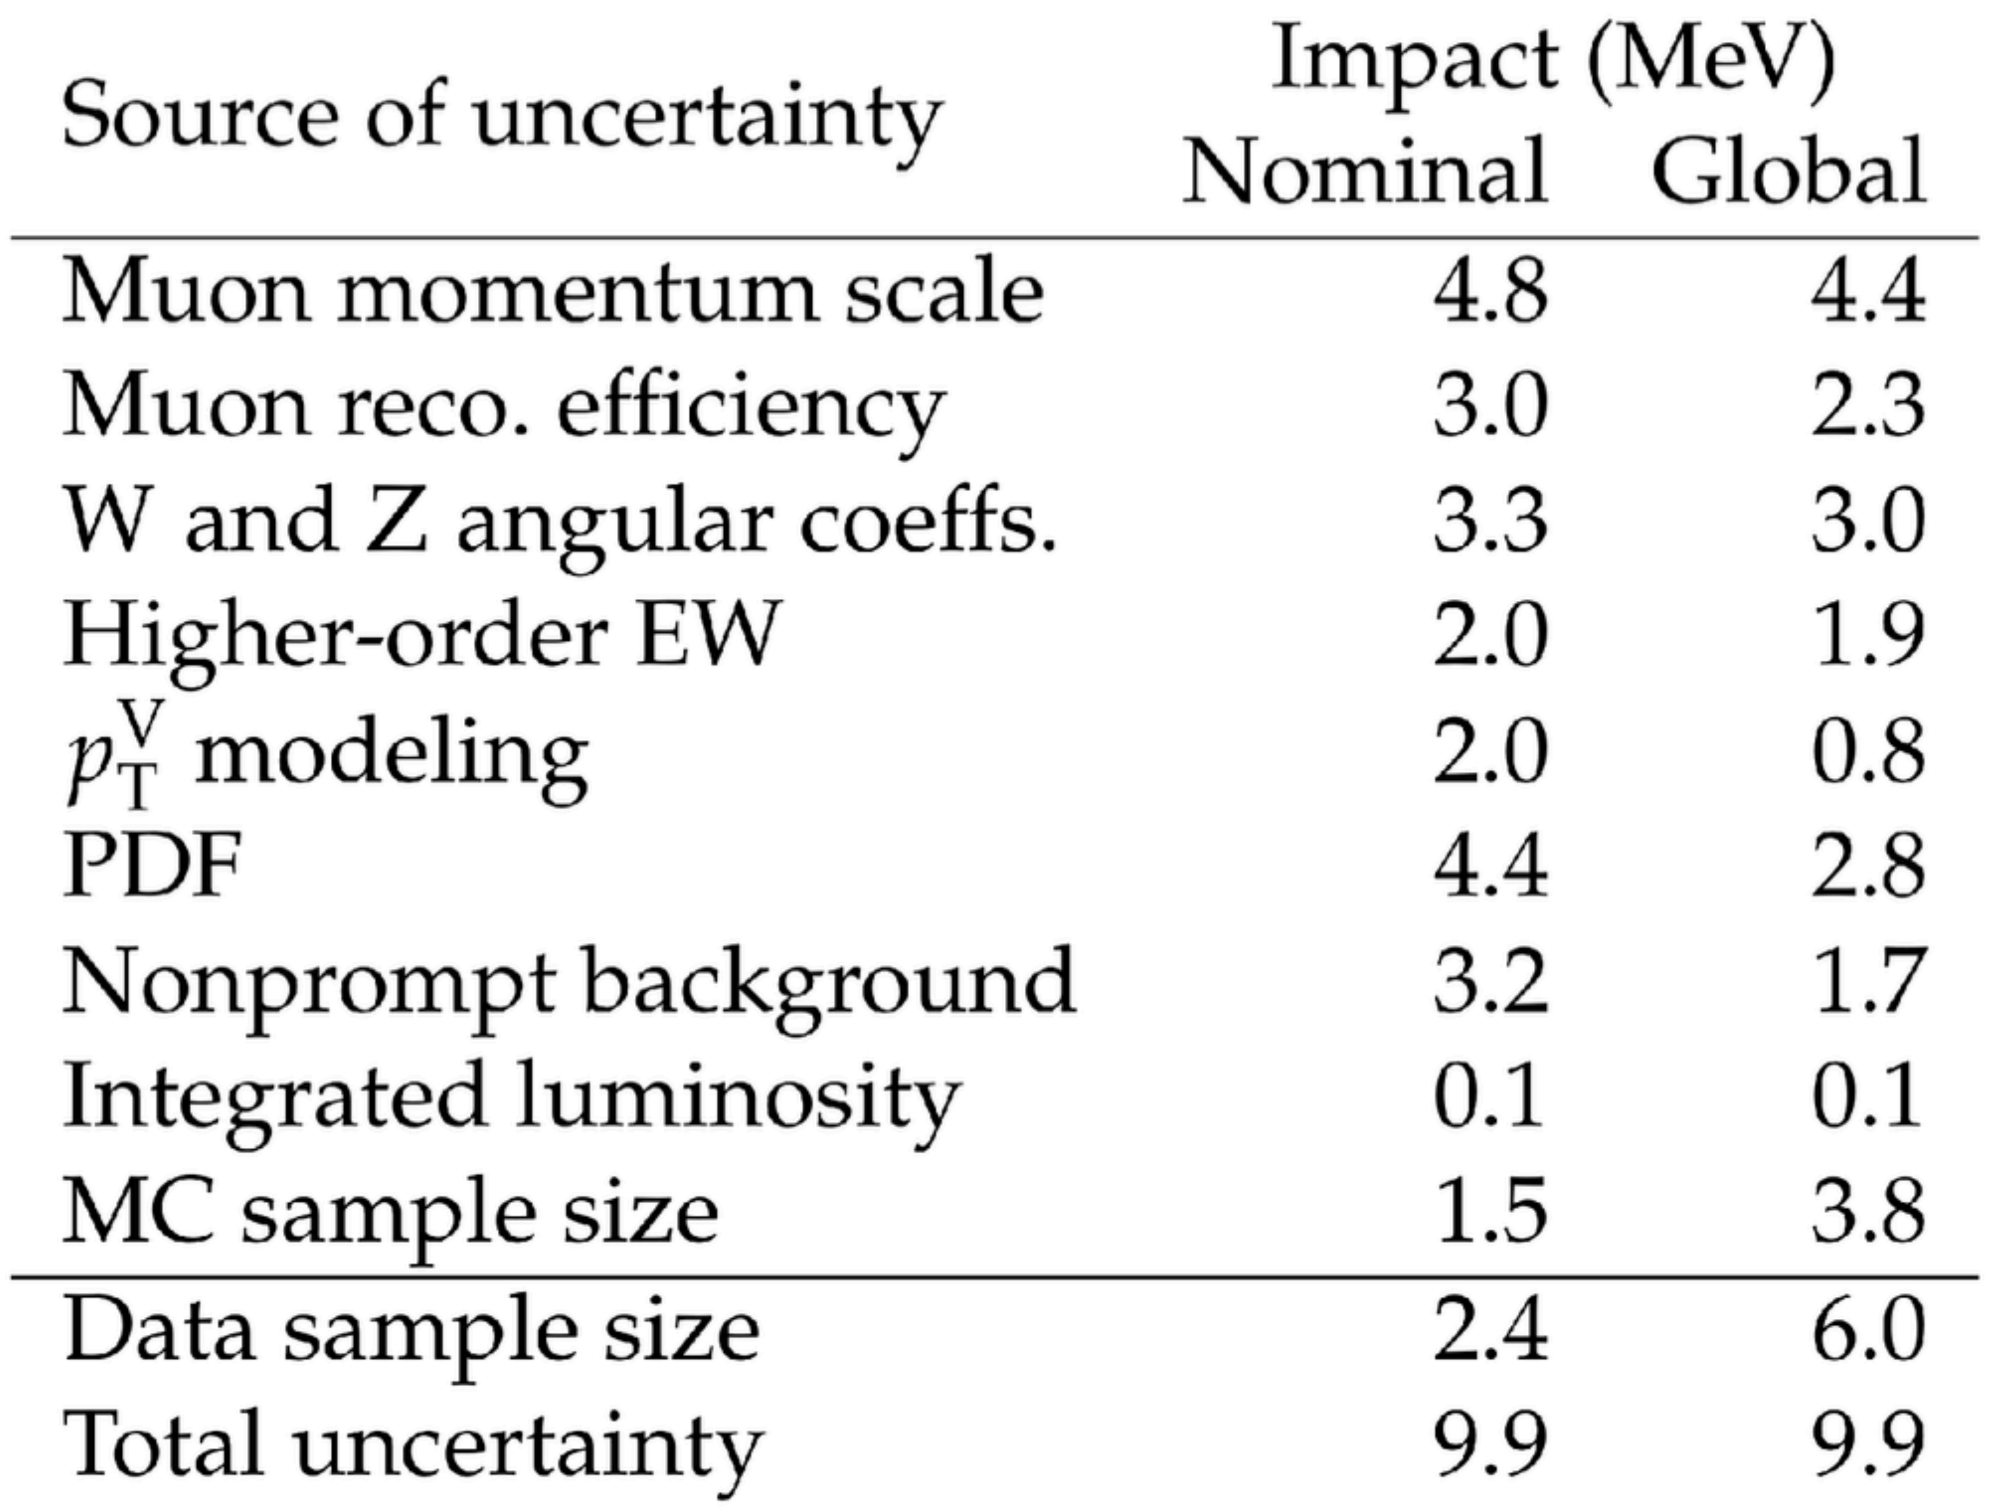


★ Extracting m_W from fit to (η^μ, p_T^μ)

- Total uncertainty of 9.9 MeV
  - Muon momentum scale and PDF dominant

$$\boxed{m_W = 80360.2 \pm 9.9\,\text{MeV}}$$





Source of uncertainty	Impact (MeV) Nominal	Impact (MeV) Global
Muon momentum scale	4.8	4.4
Muon reco. efficiency	3.0	2.3
W and Z angular coeffs.	3.3	3.0
Higher-order EW	2.0	1.9
p_T^V modeling	2.0	0.8
PDF	4.4	2.8
Nonprompt background	3.2	1.7
Integrated luminosity	0.1	0.1
MC sample size	1.5	3.8
Data sample size	2.4	6.0
Total uncertainty	9.9	9.9

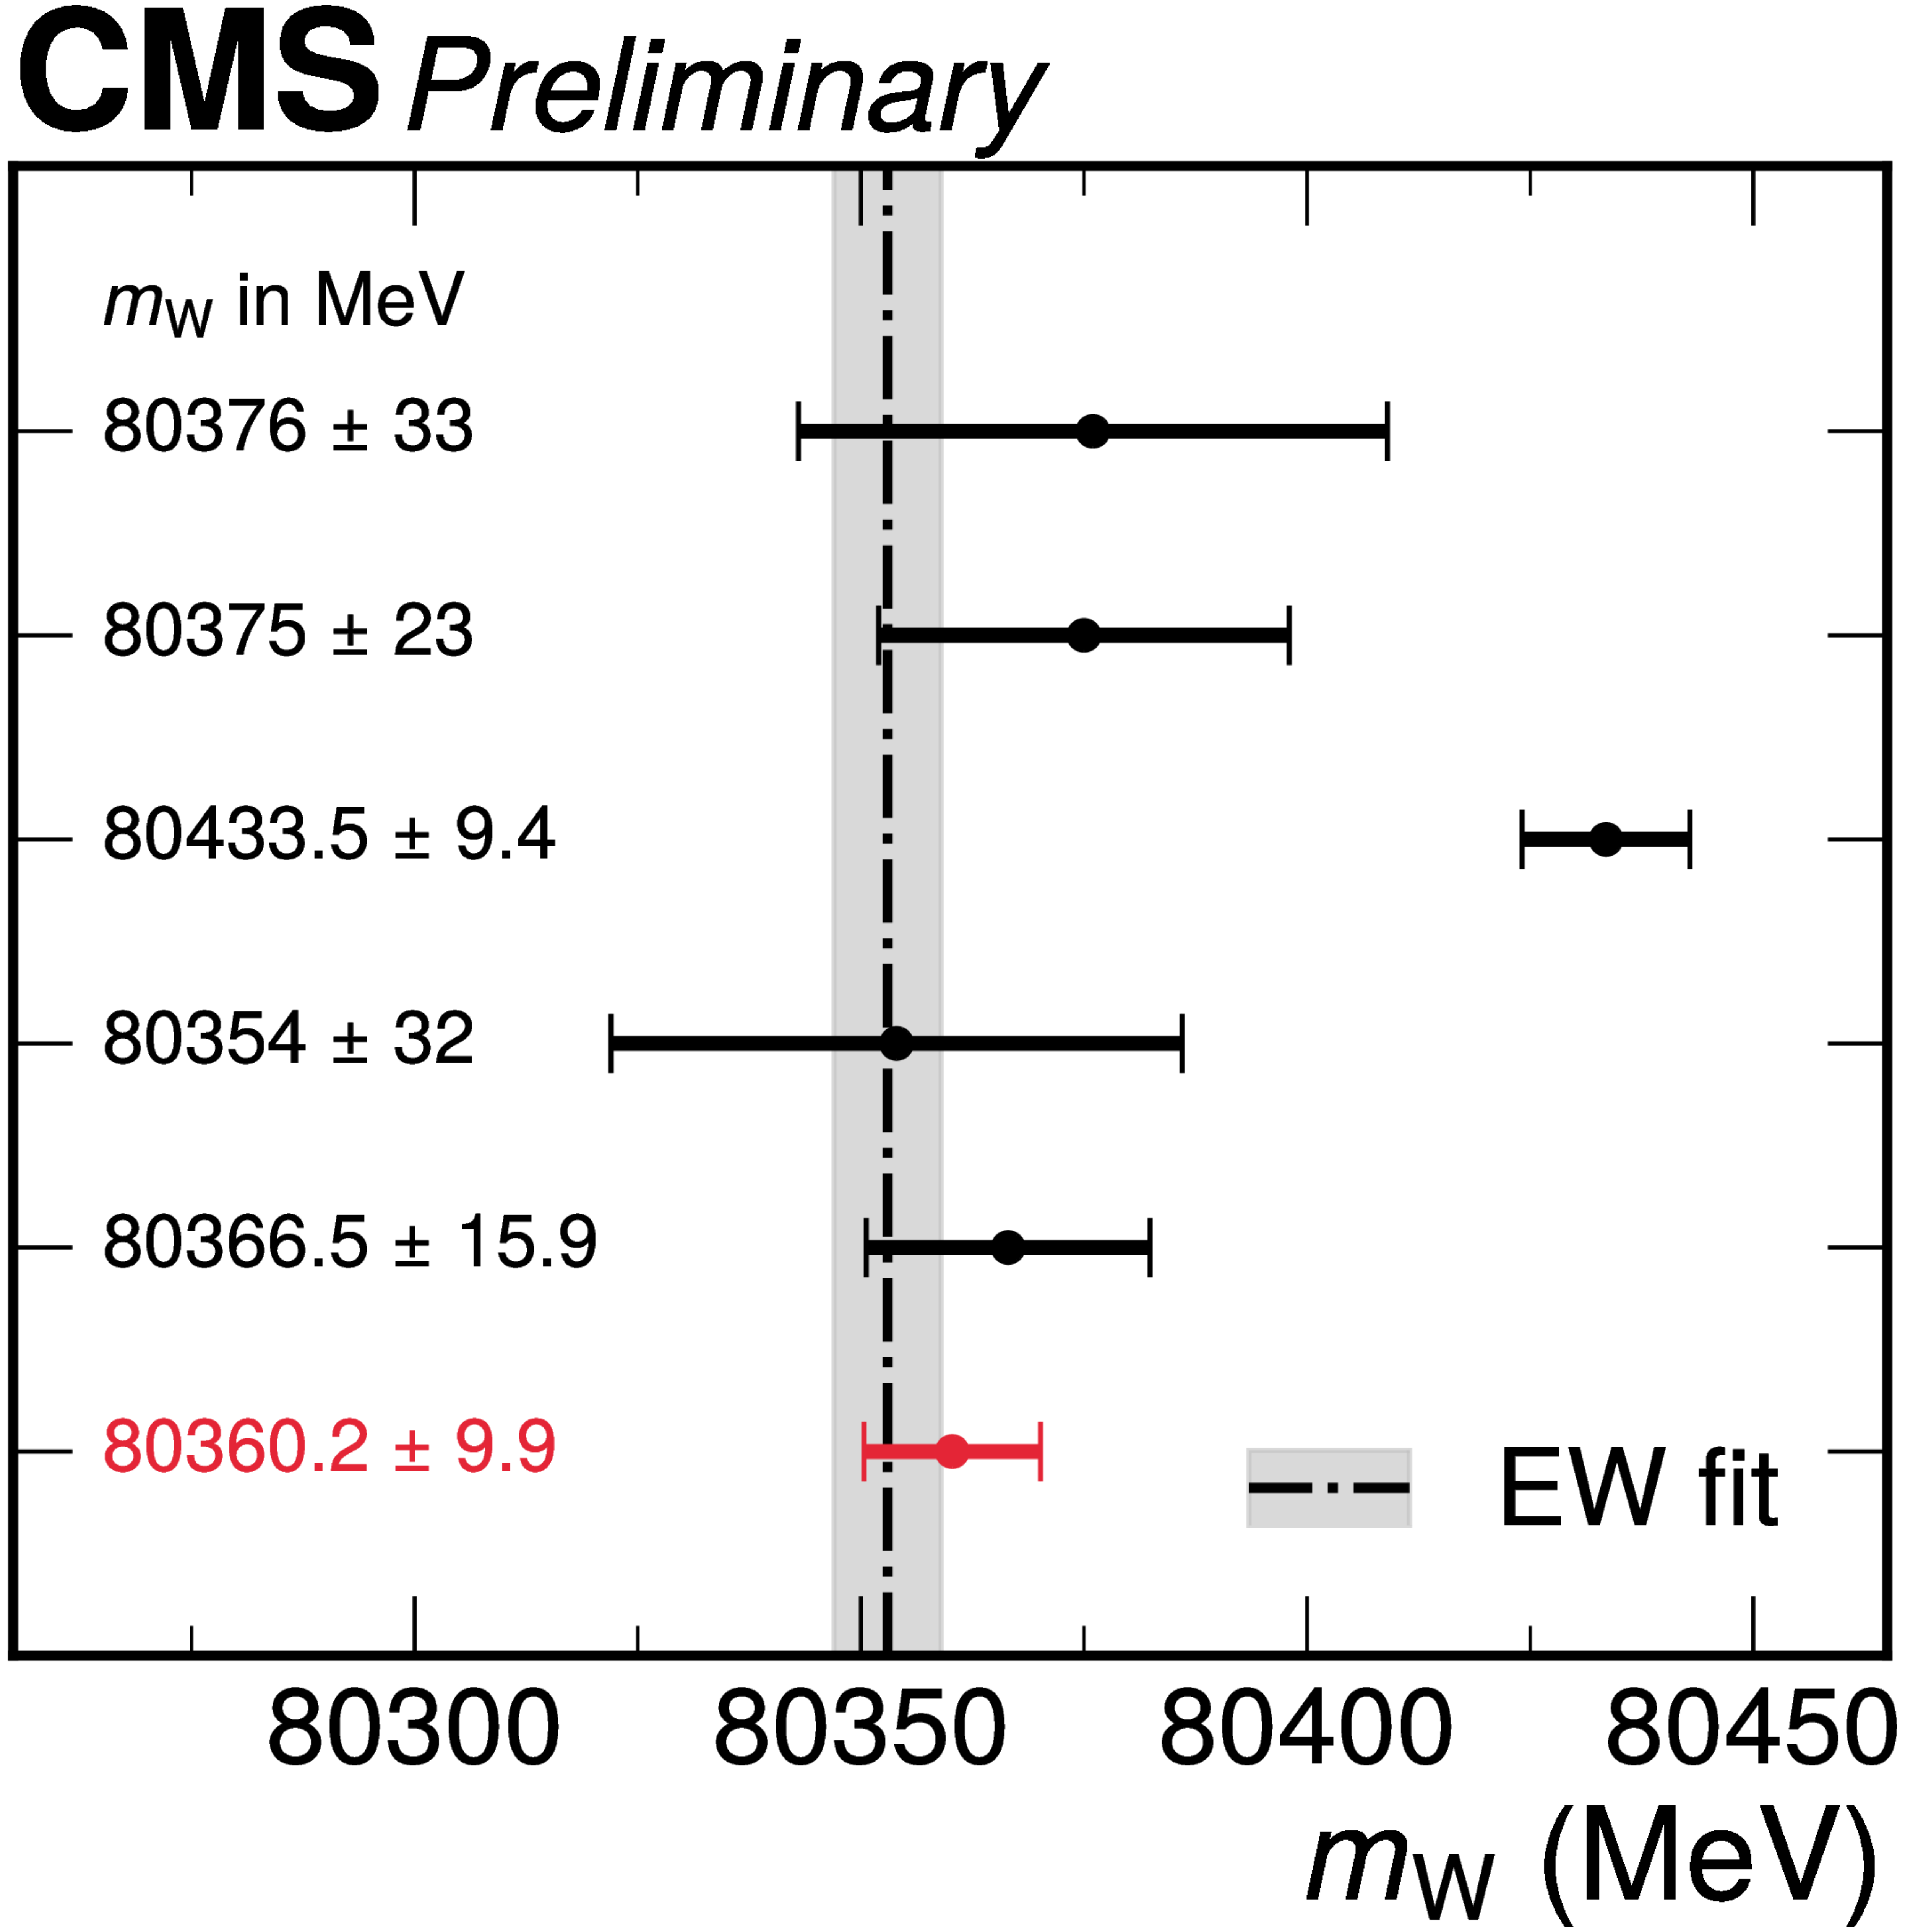
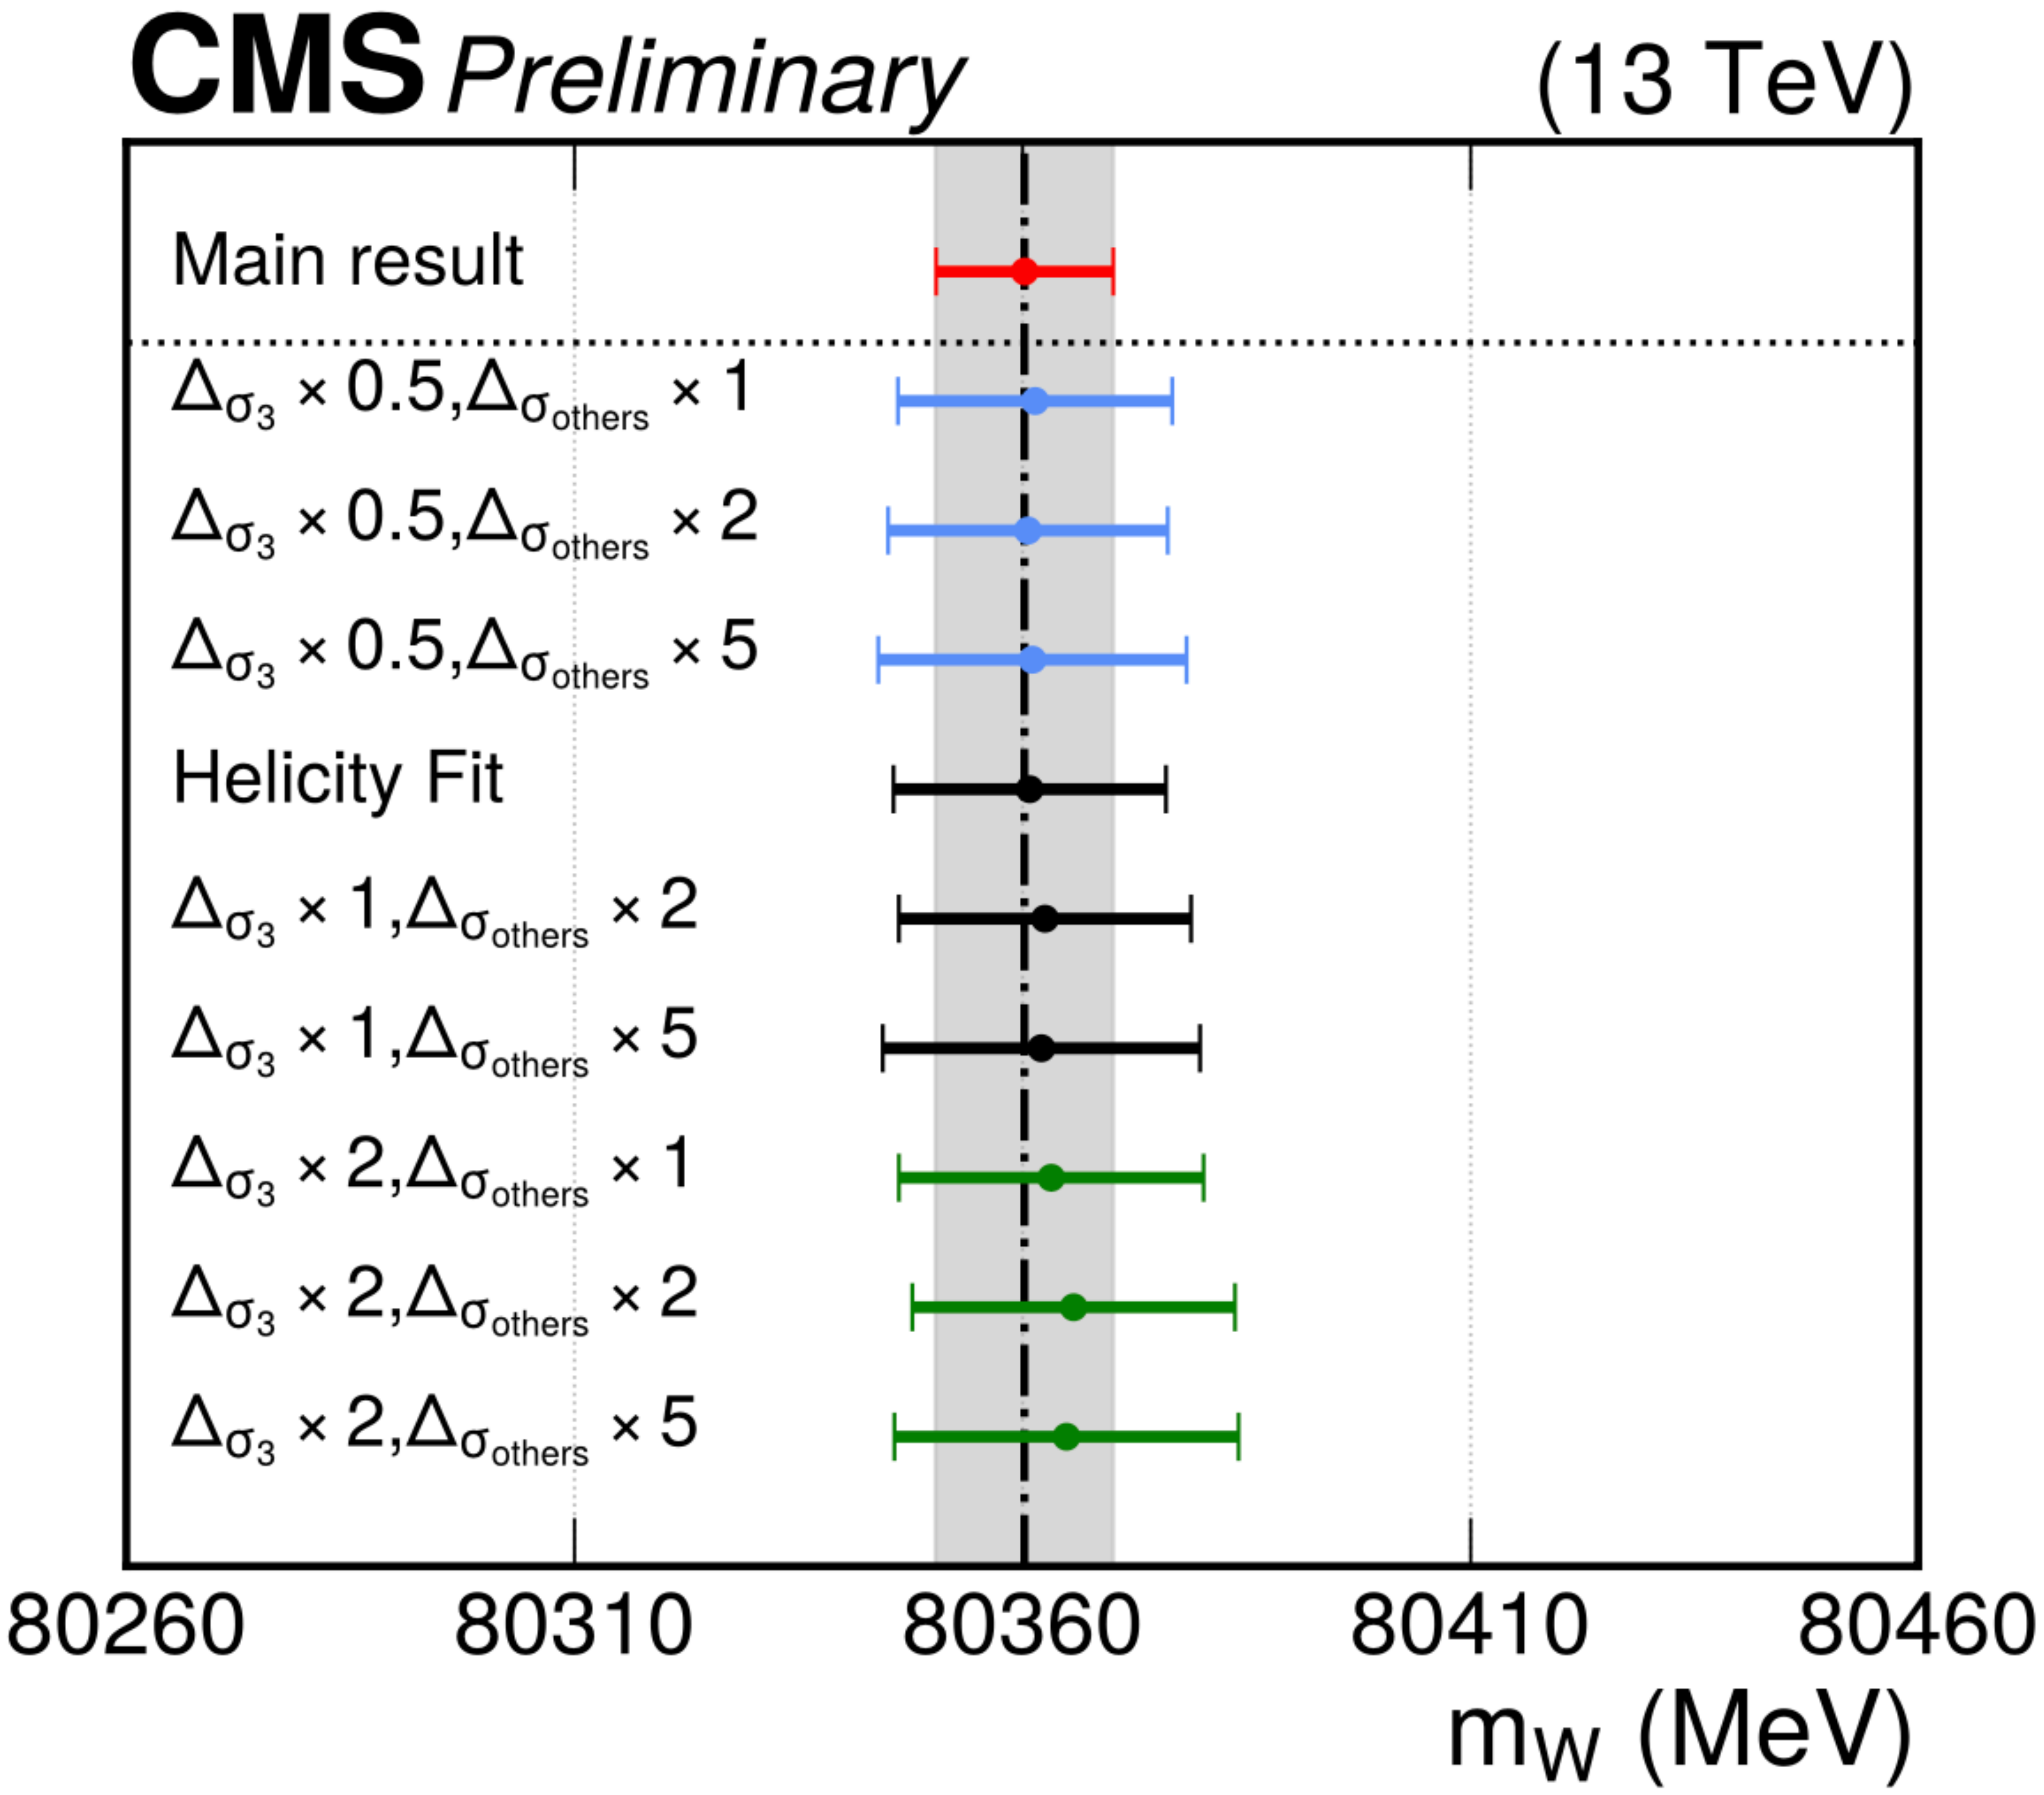
This Work



Helicity cross section fit result

$$\boxed{m_W = 80360.8 \pm 15.2\mathrm{MeV}}$$

- Helicity cross section fit result very compatible with the nominal
  - Larger uncertainties by design
- Result istable wrt looser or tighter initial constraints on the helicity cross sections

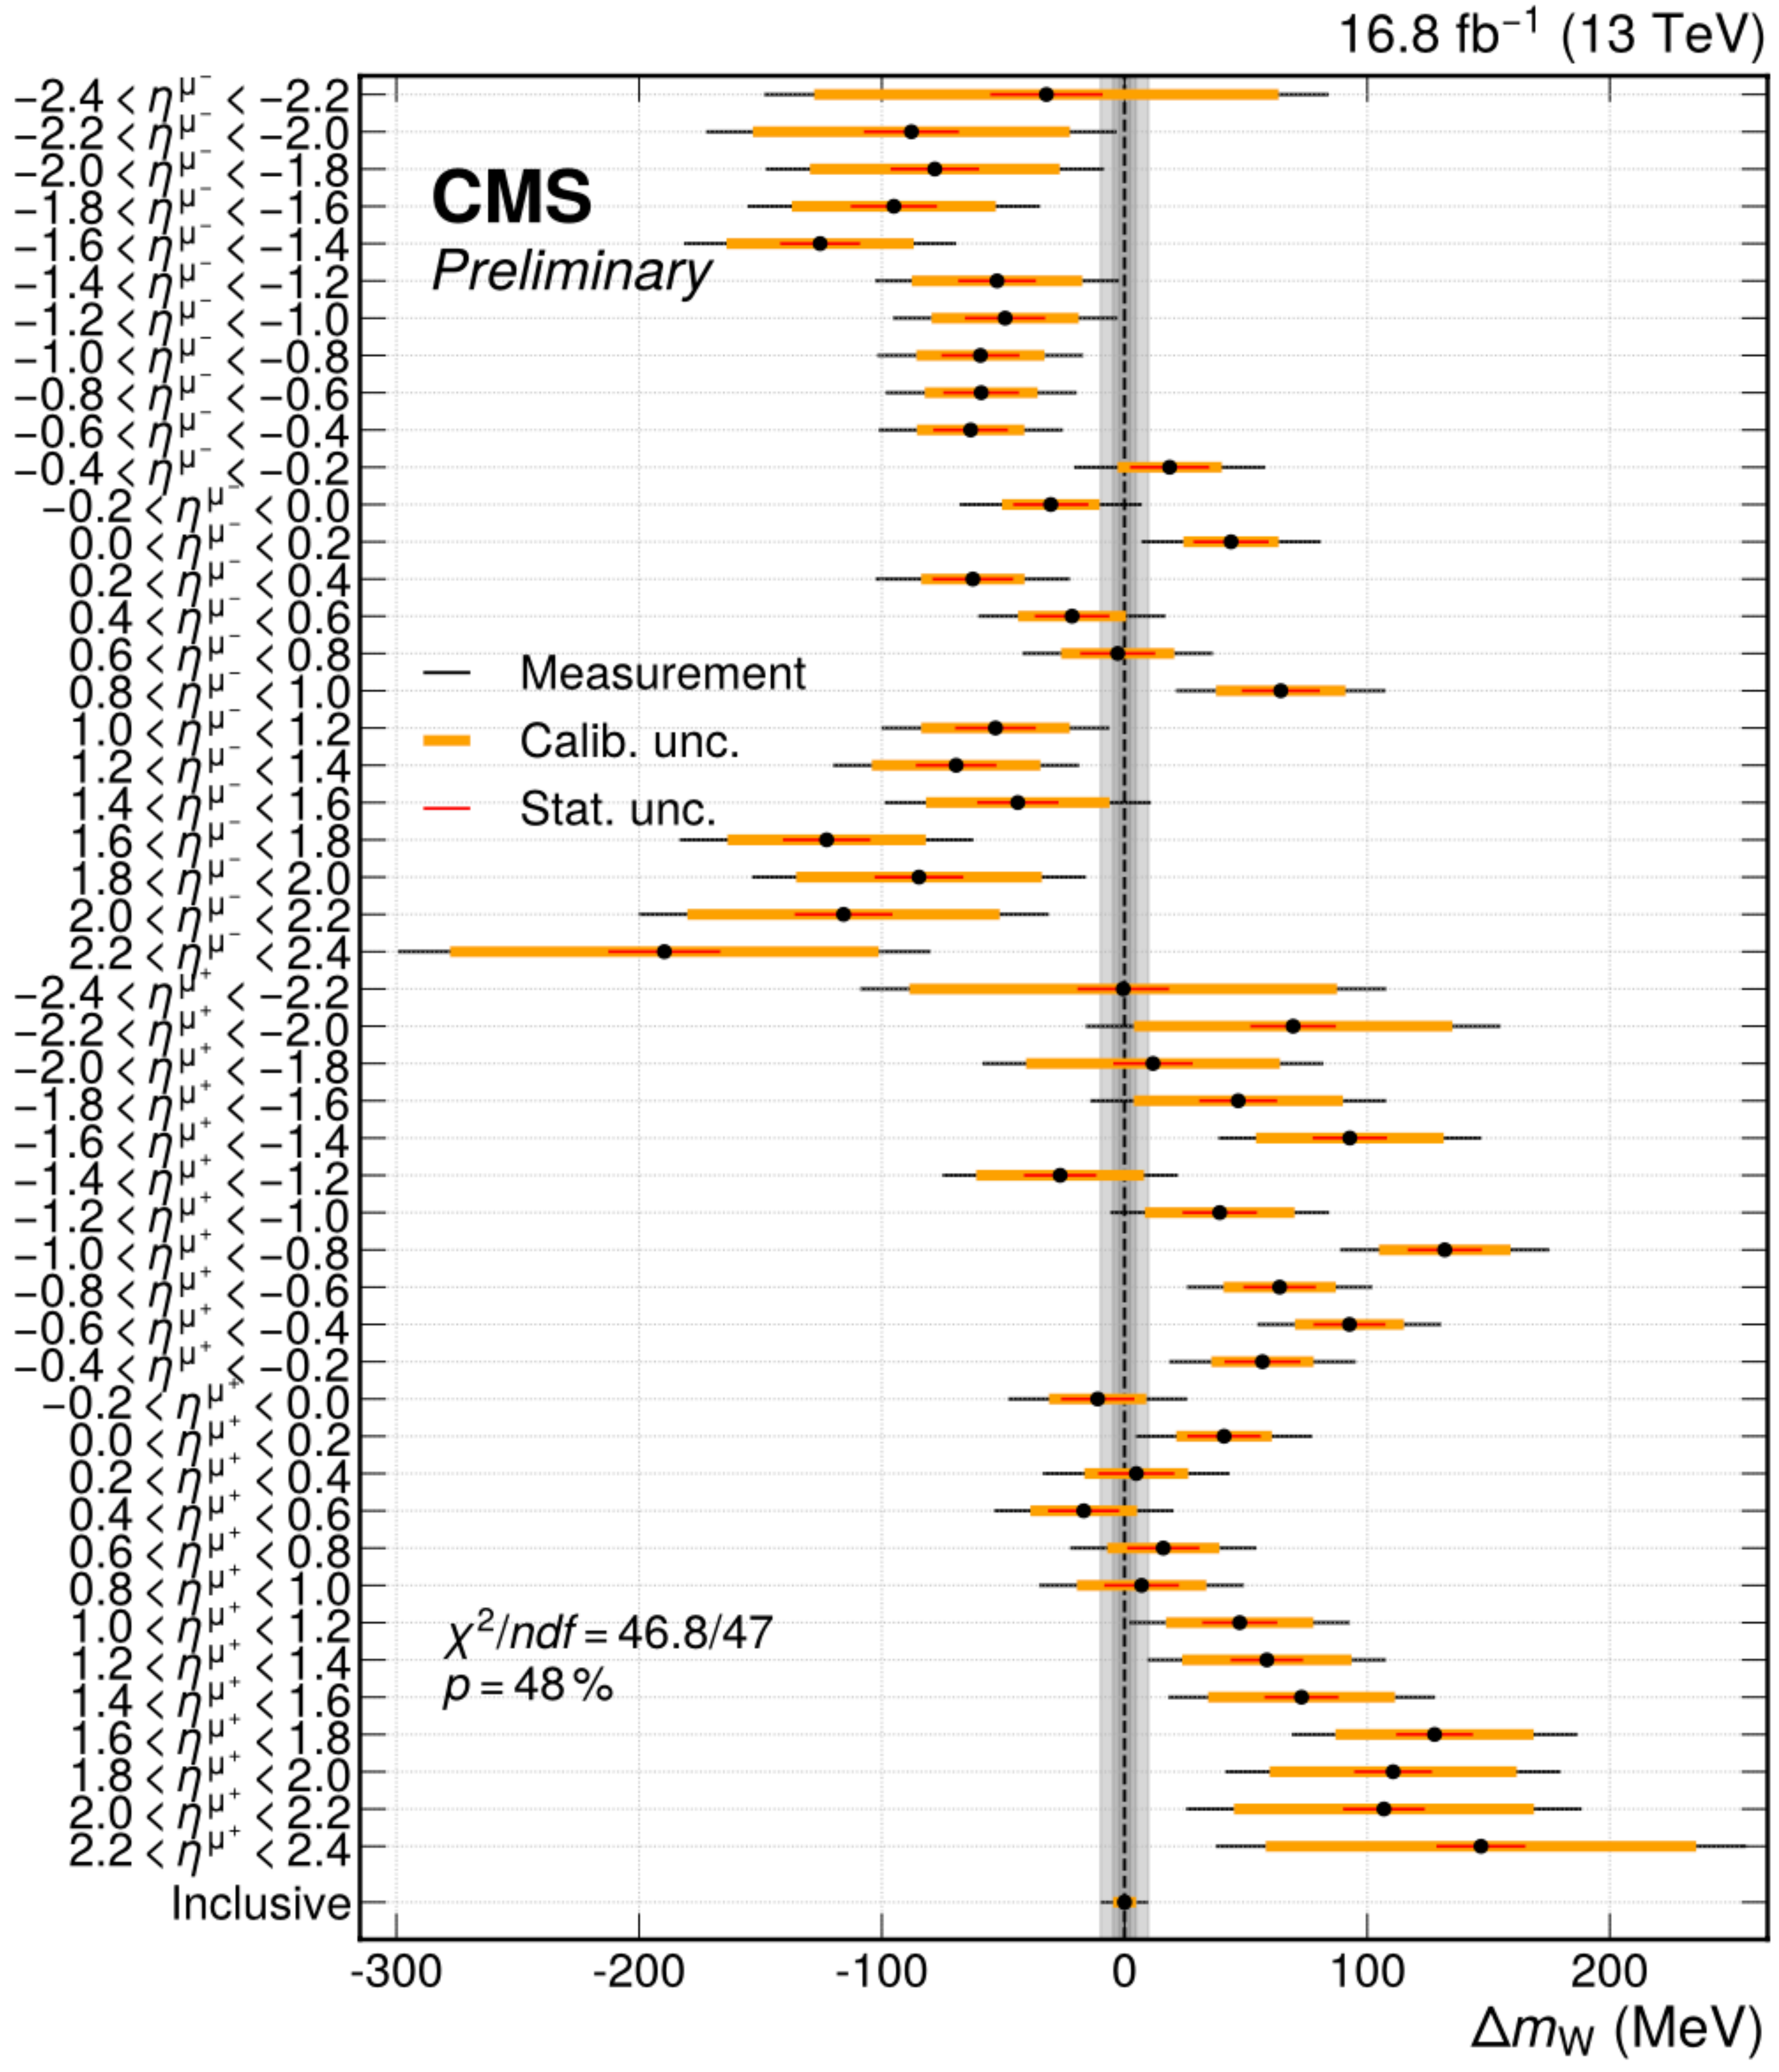


Experimental validation

- Compatibility tested when allowing different m_W parameters per η/charge regions
- Mass difference between
  - η < 0 and η > 0: 5.8 ± 12.4 MeV
  - Barrel vs. endcap: 15.3 ± 14.7 MeV
  - W+ vs. W- 57± 30 MeV

- Charge difference studied extensively, and no clear issues found.
  - m_{W^+} and m_{W^-} are highly anti-correlated (-40%)
  - Only 2% correlation betwee m_{W^+} and m_{W^-}

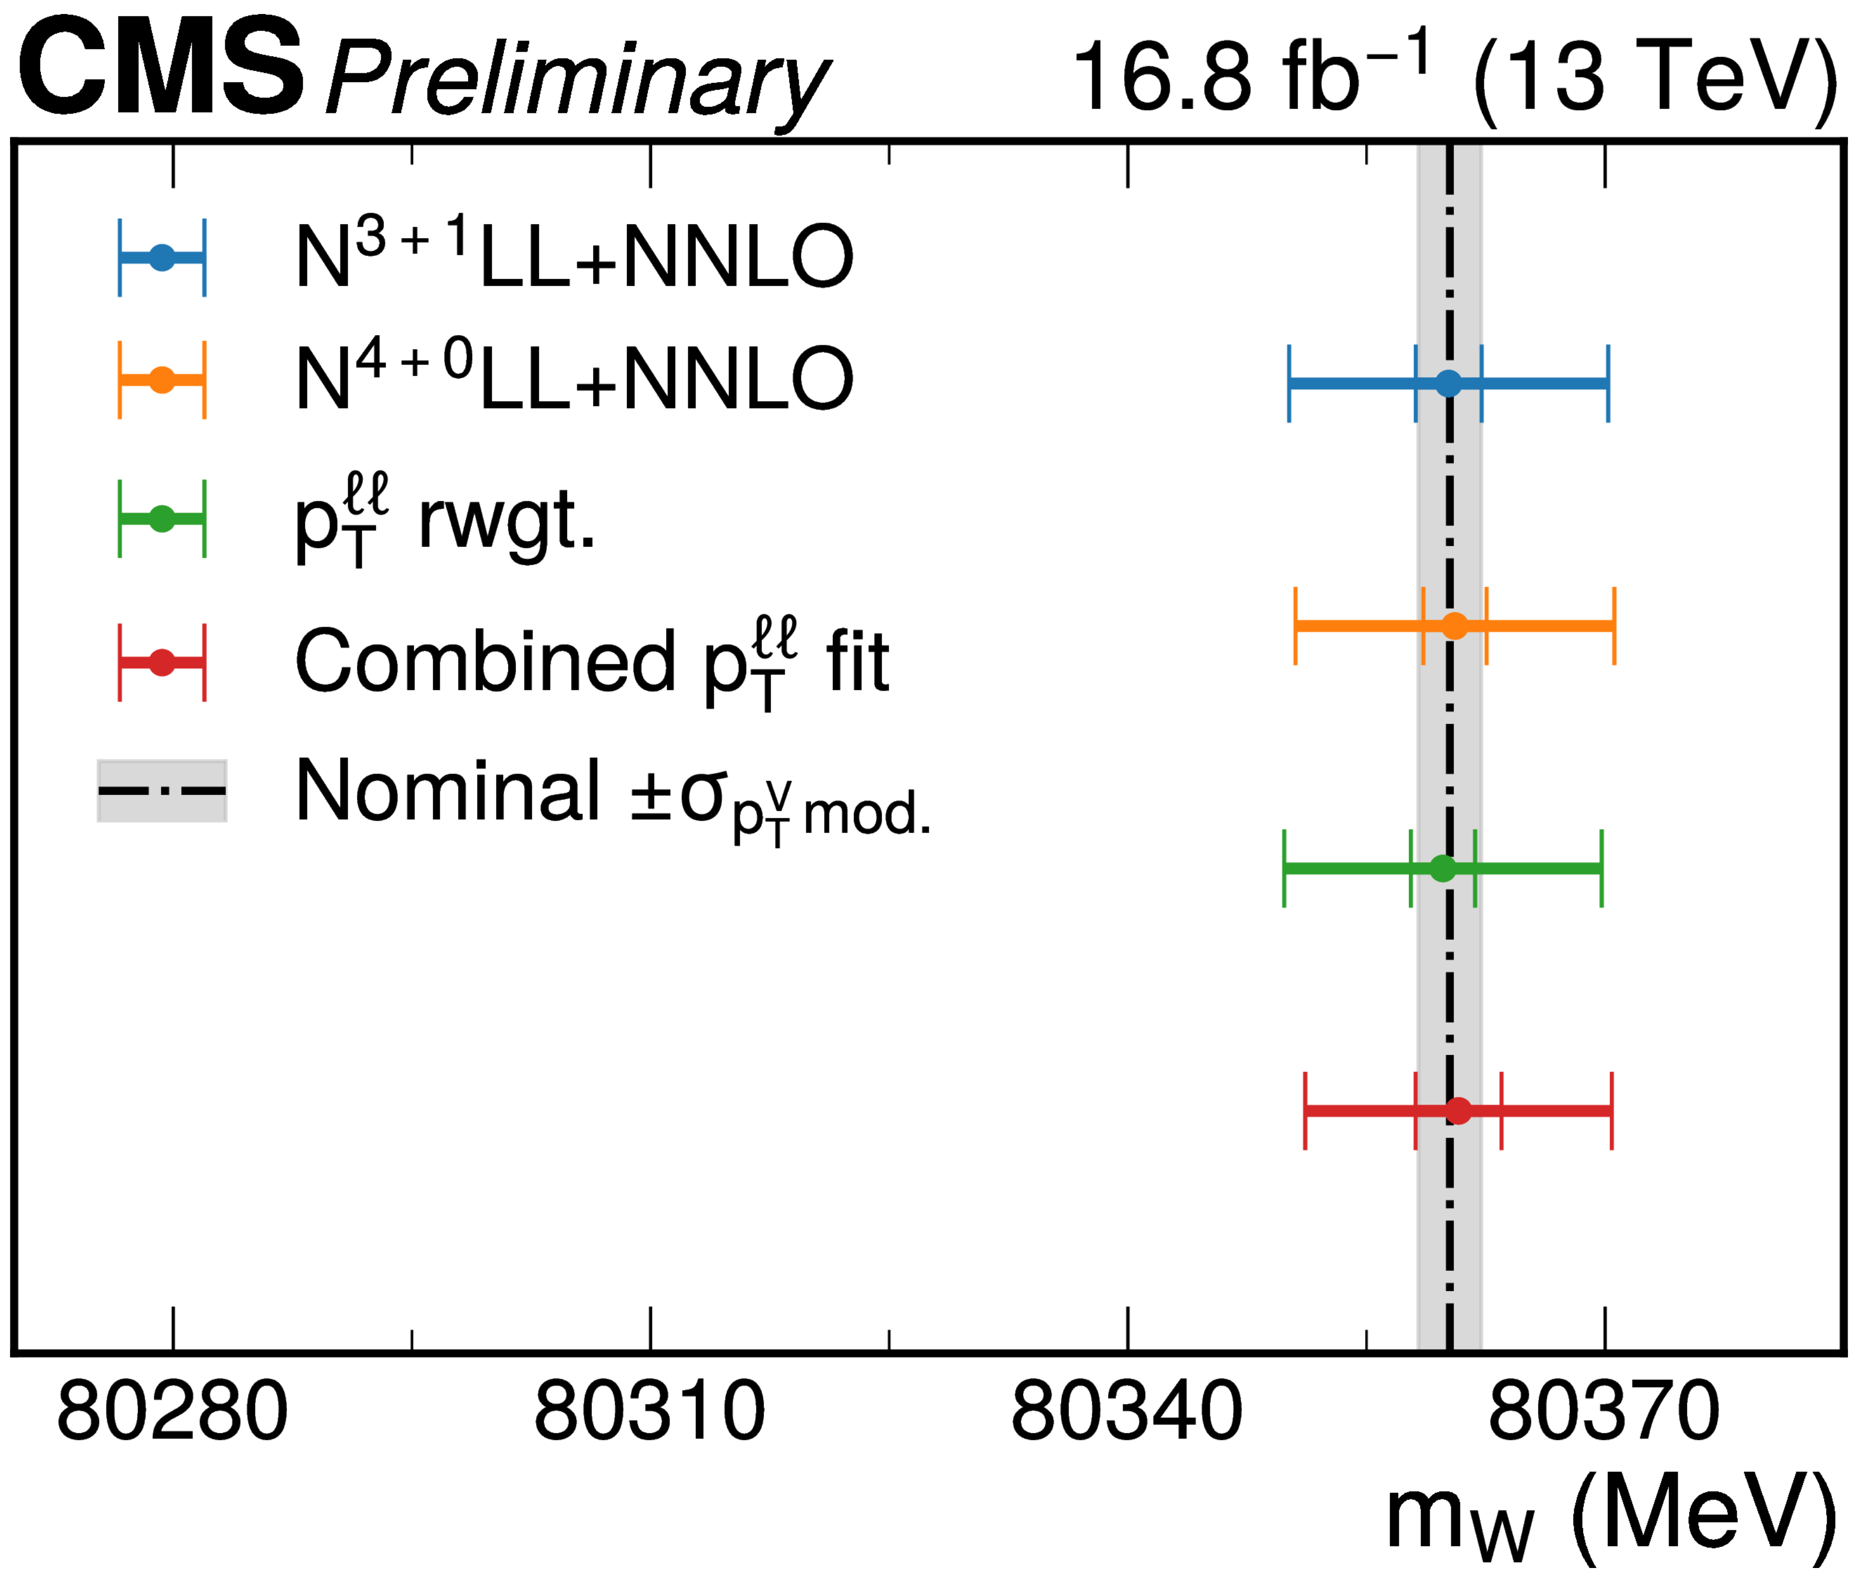
➡Even if some small charge-dependent correction is underestimated, impact in m_W is very small

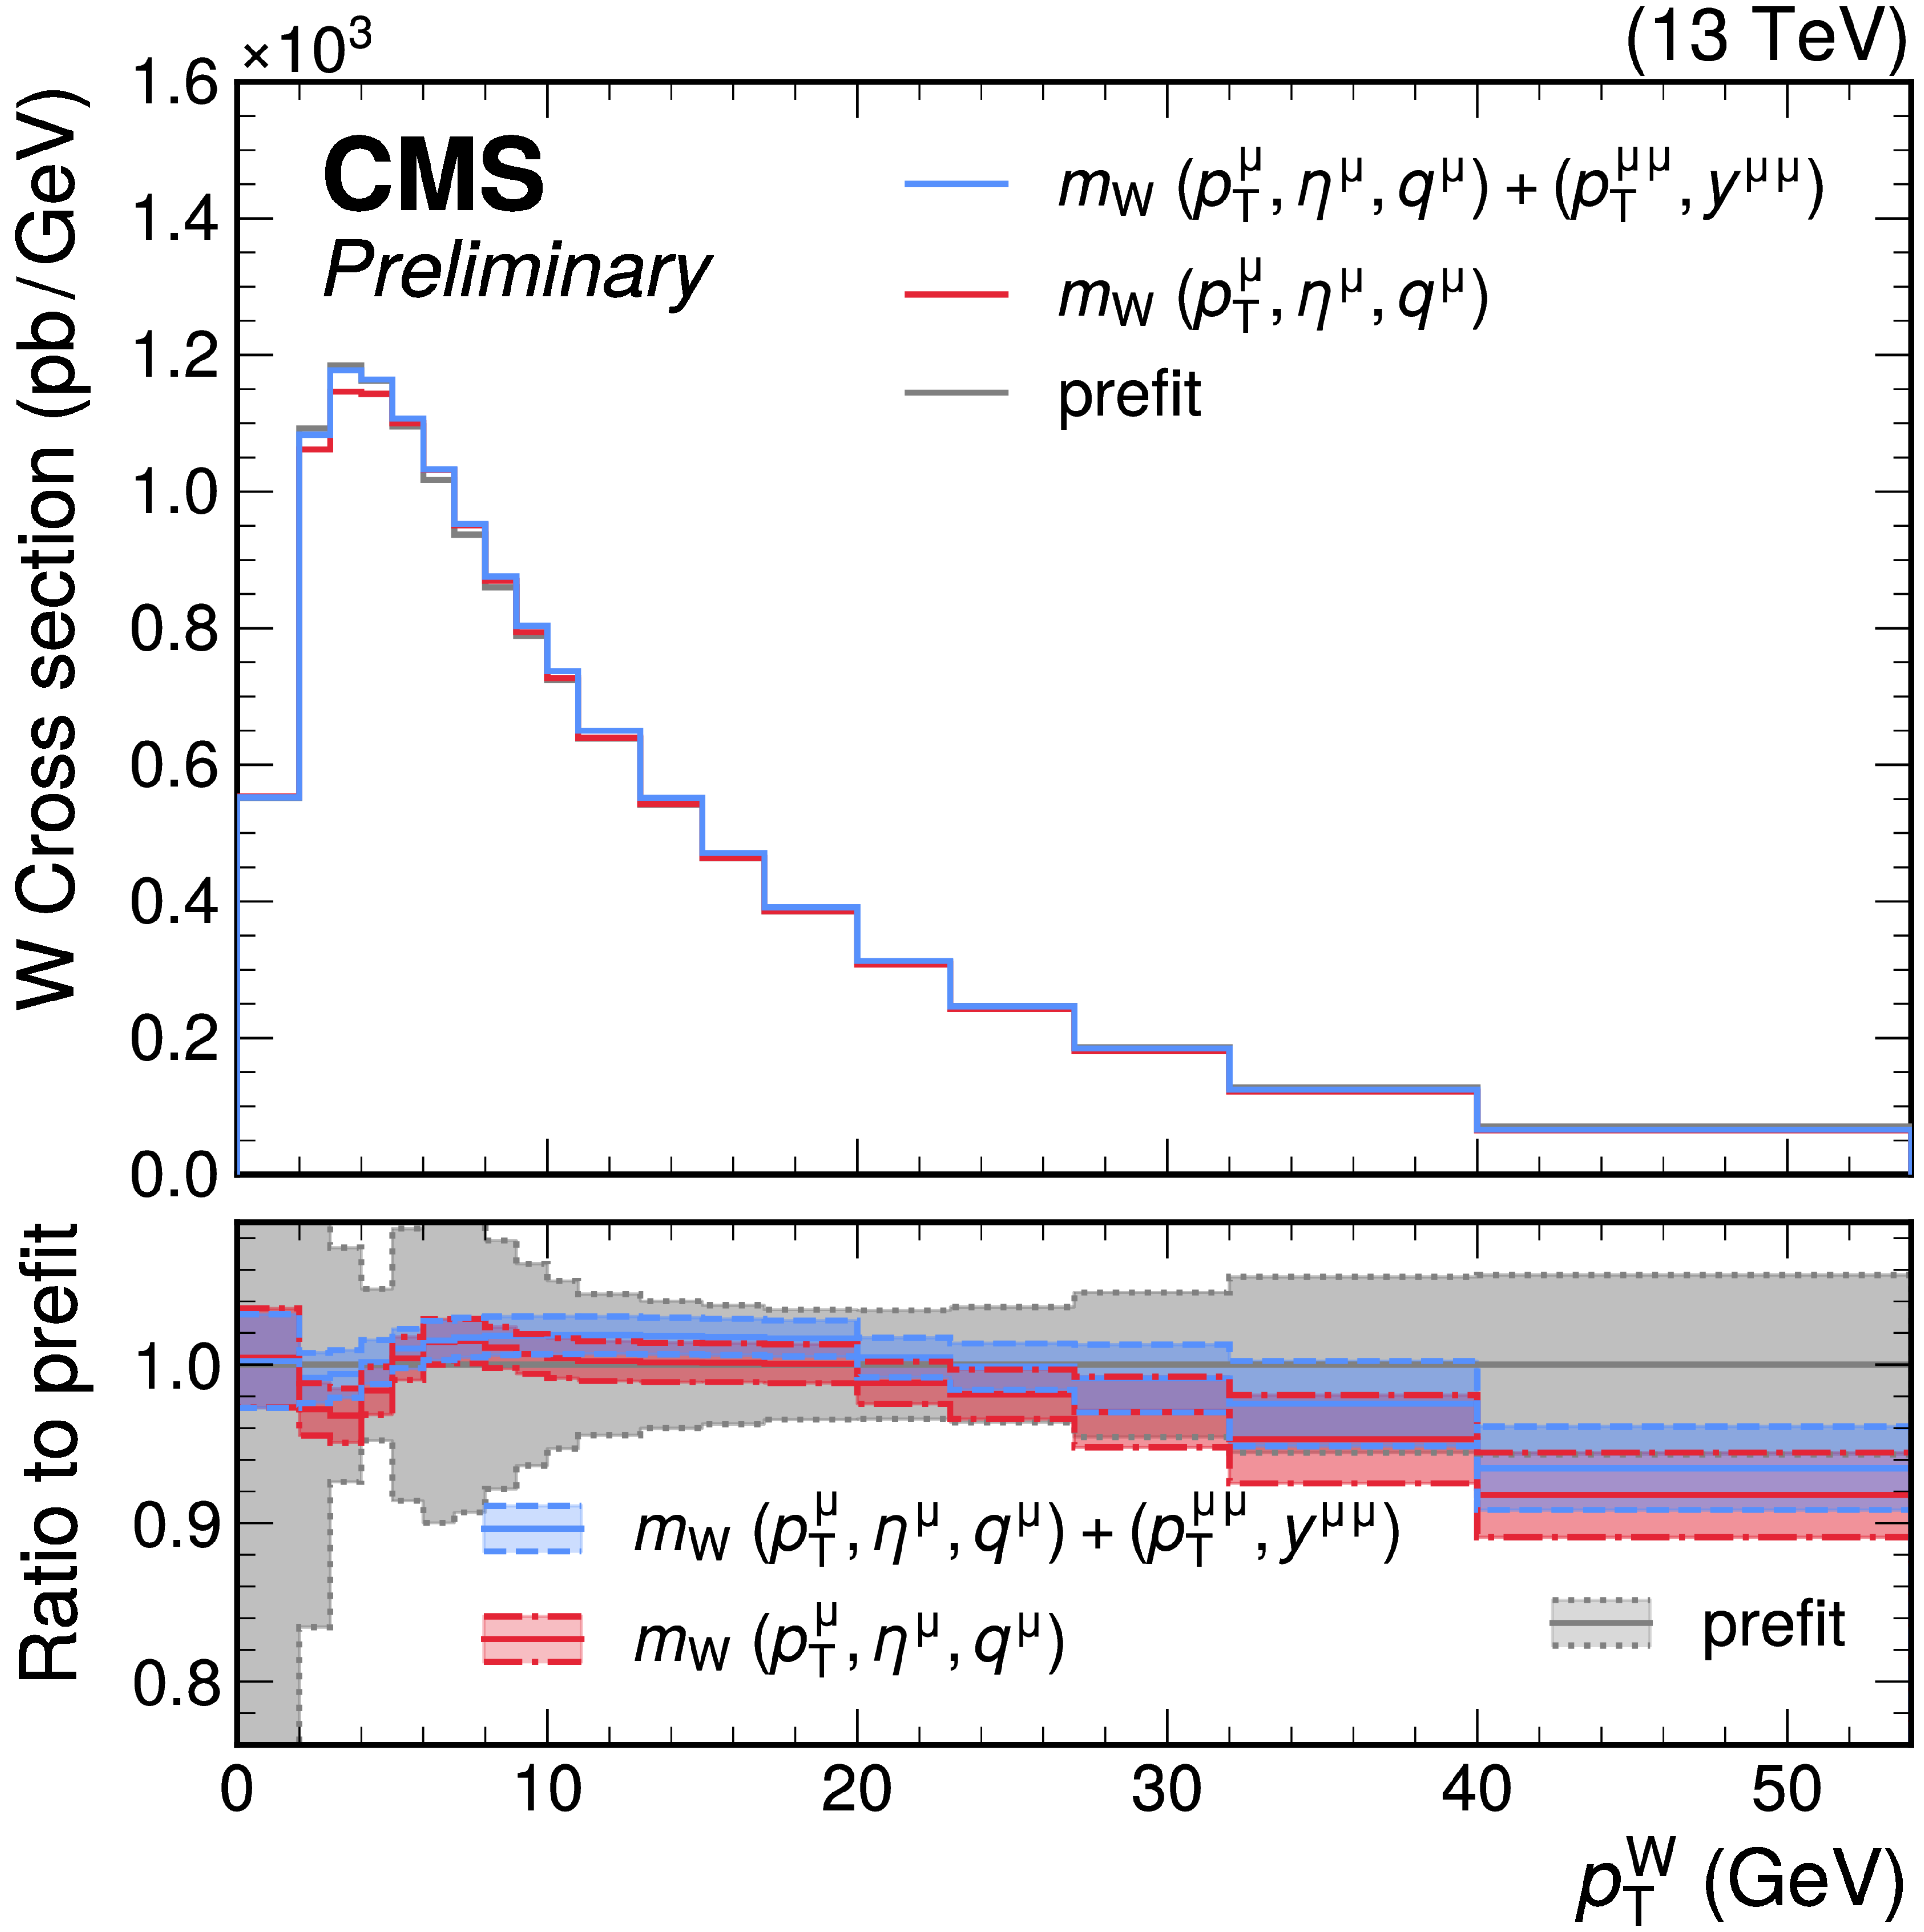


Impact of modeling and validation

- Tested effect of varying treatment of theoretical uncertainties
  - Partial high-order resummation + theory nuisance parameters
  - Explicit reweighing of p_T^W by measured p_T^Z correction
  - Combined m_W + $p_T^{\mu\mu}$ fit

➡All results consistent with nominal approach

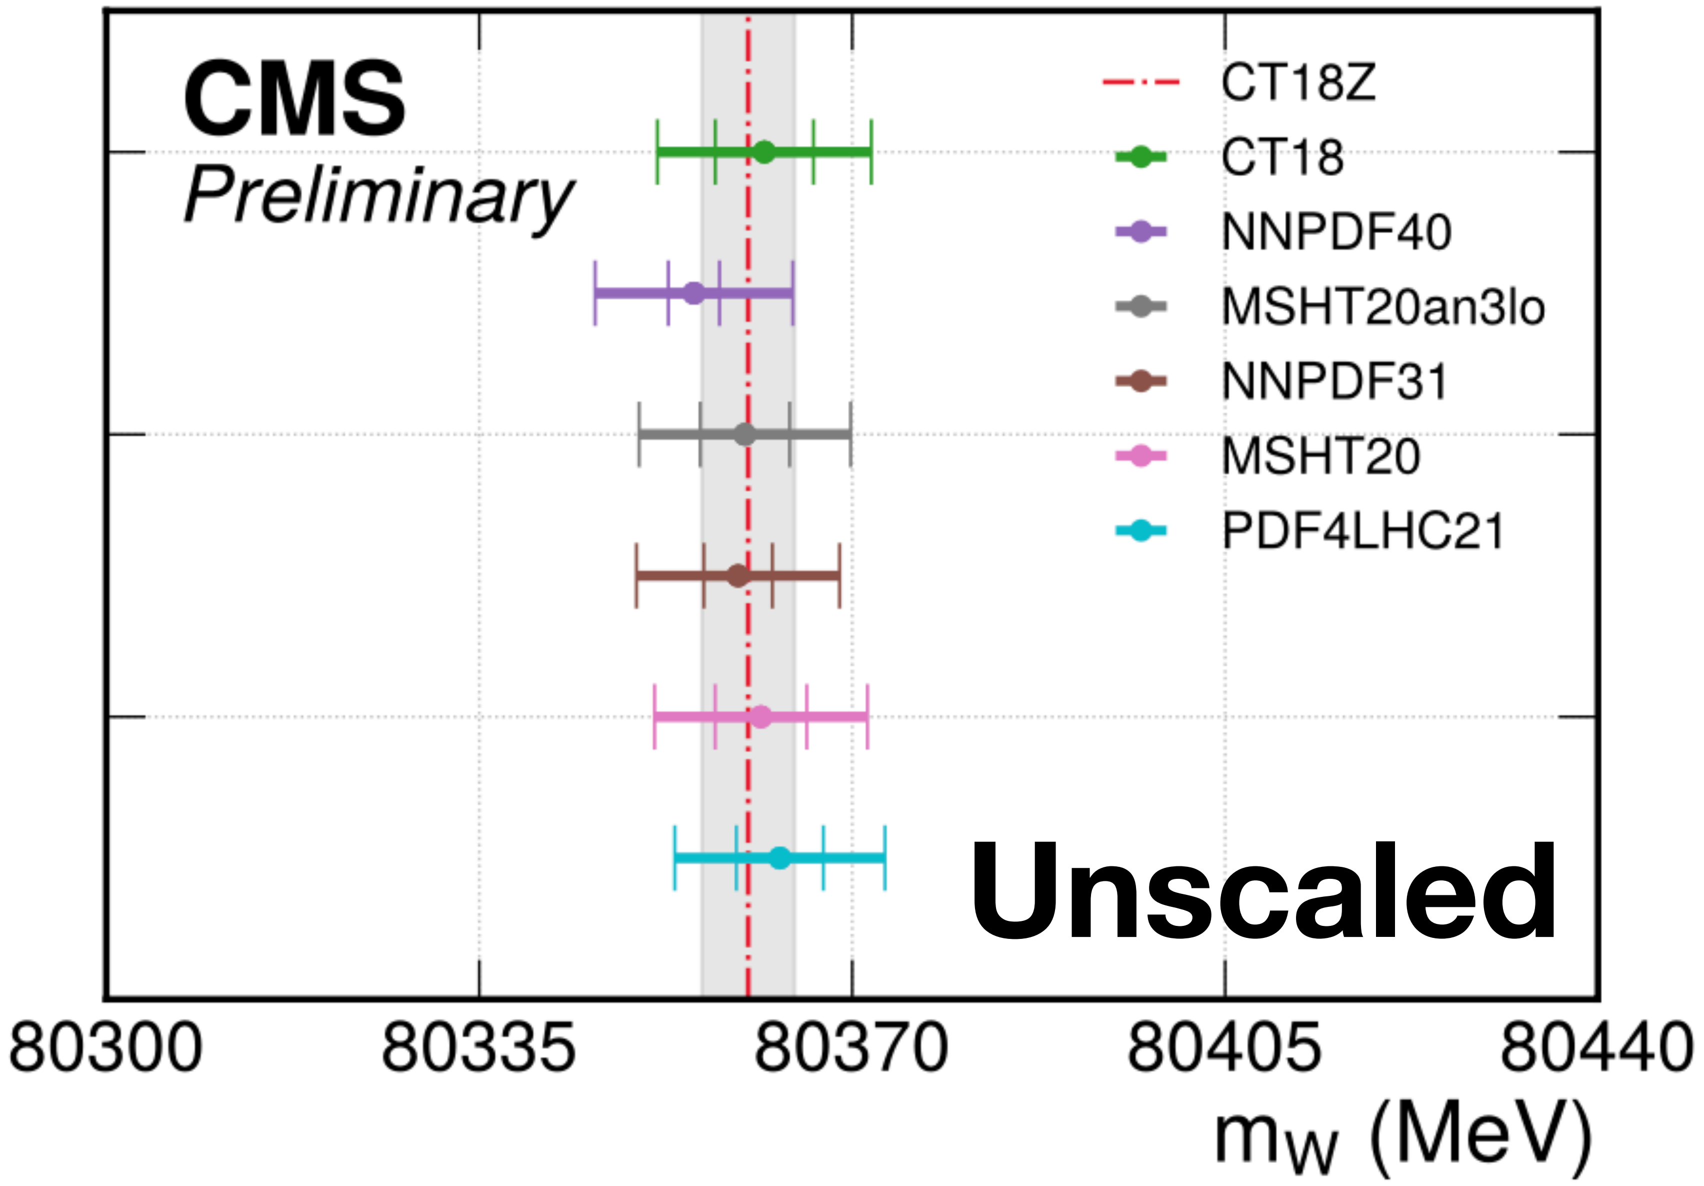


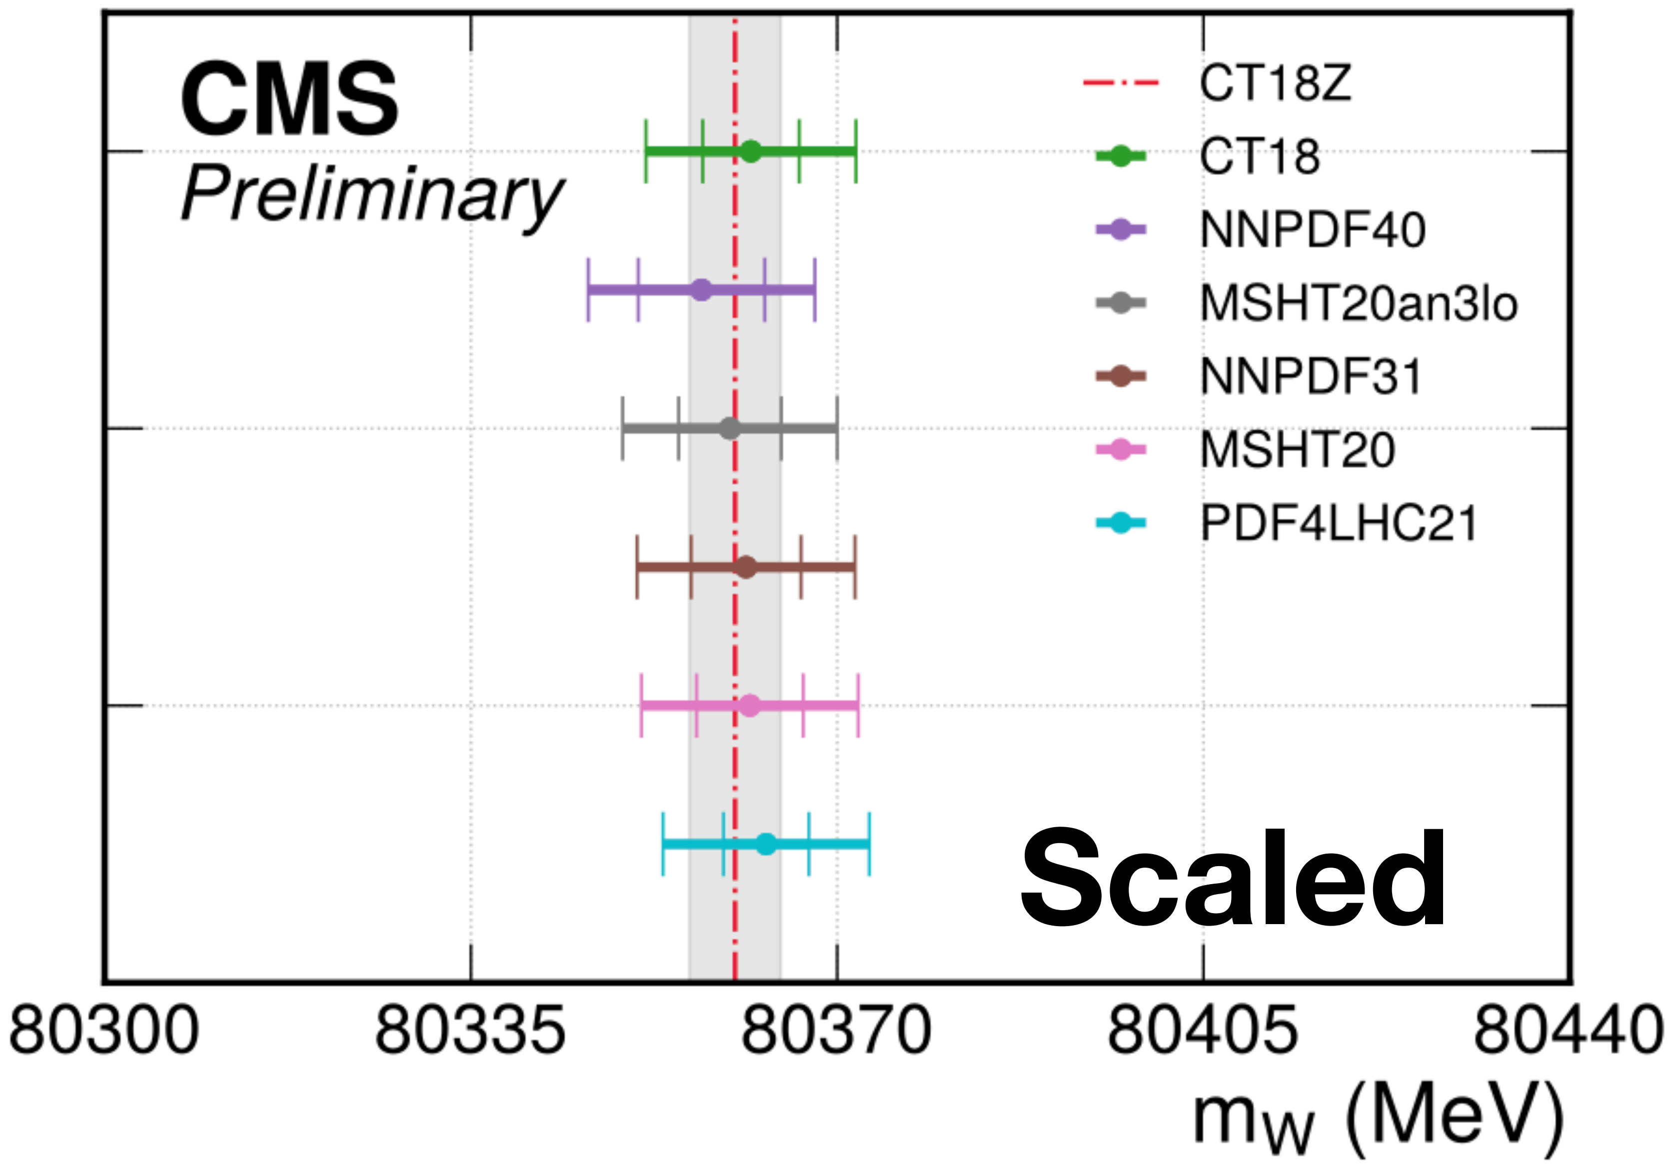


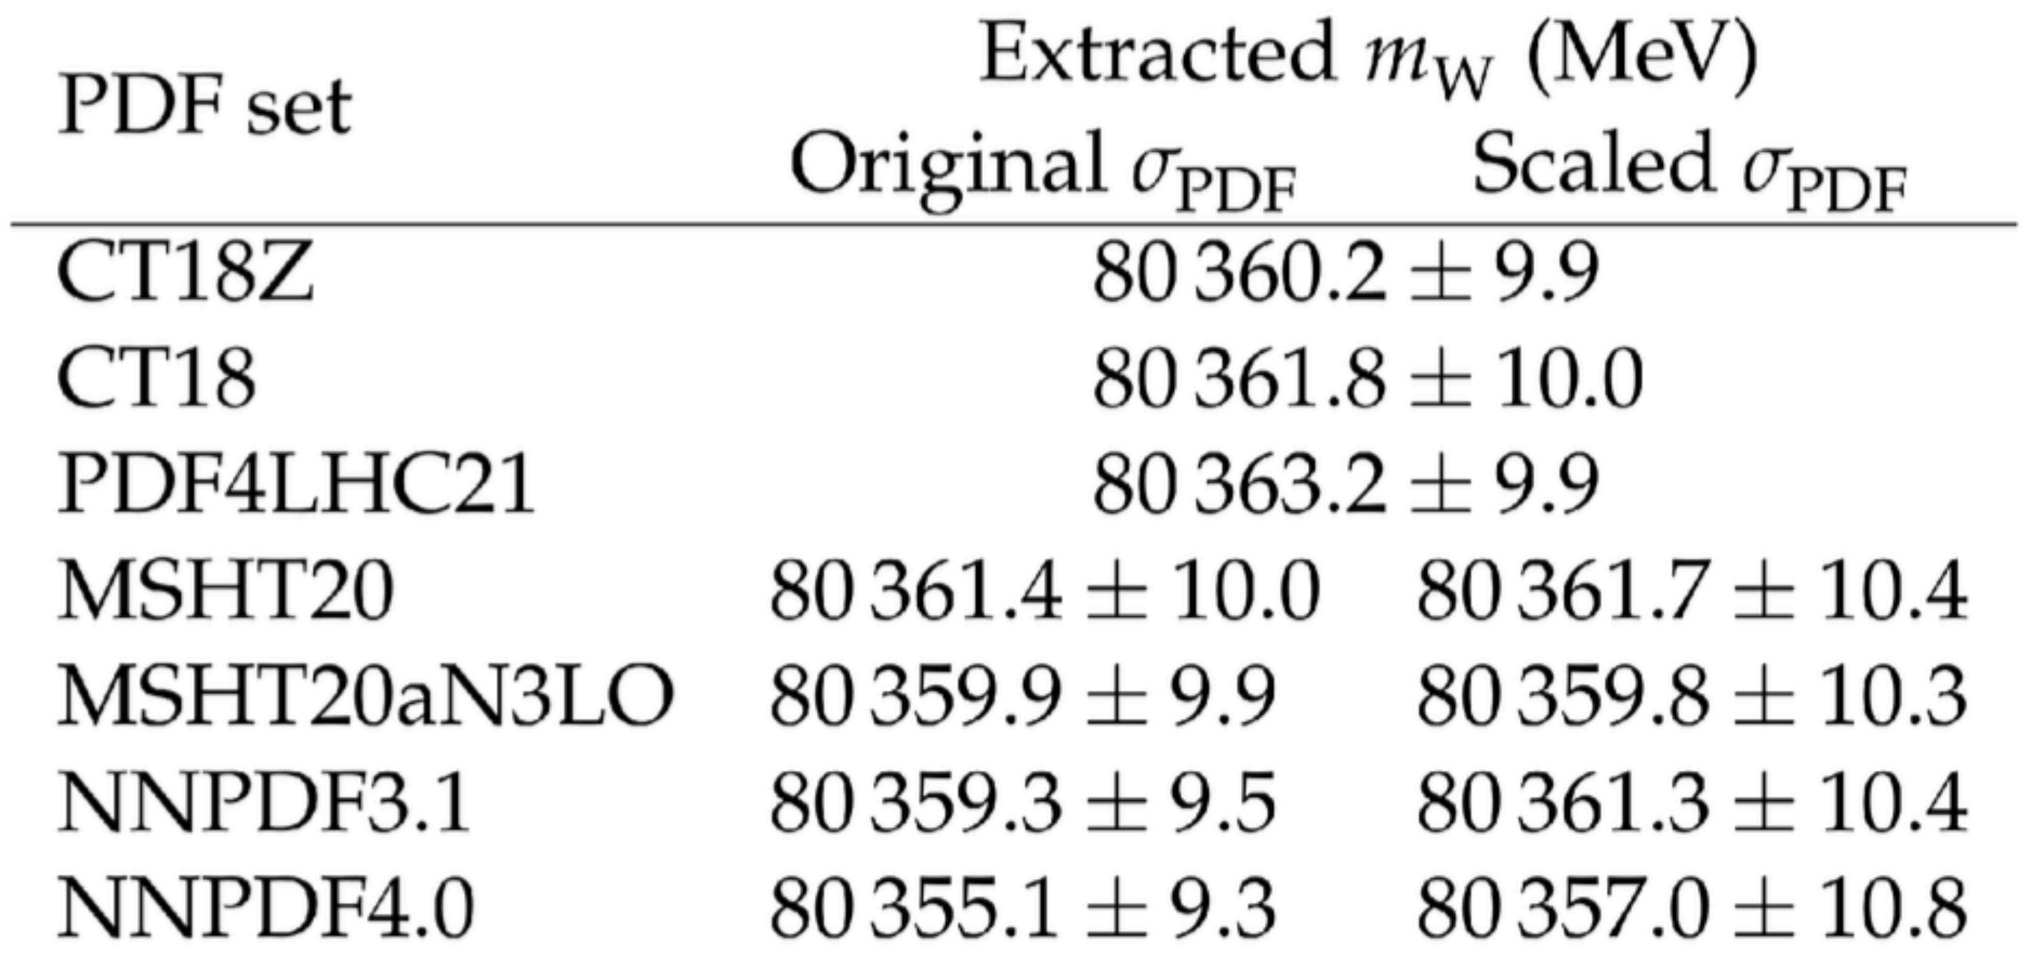
Comparison of generator-level postfit distributions from nominal and combined m_W + $p_T^{\mu\mu}$ fits

Results with alternative PDF sets

- Unc. scaling reduces spread of results, brings all within nominal uncertainty







PDF set	Extracted m_W (MeV)	
	Original σ_{PDF}	Scaled σ_{PDF}
CT18Z	$80\,360.2 \pm 9.9$	
CT18	$80\,361.8 \pm 10.0$	
PDF4LHC21	$80\,363.2 \pm 9.9$	
MSHT20	$80\,361.4 \pm 10.0$	$80\,361.7 \pm 10.4$

p_T^W/p_T^Z model	1.3
Parton distributions	3.9
QED radiation	2.7
W boson statistics	6.4
Total	9.4

CDF

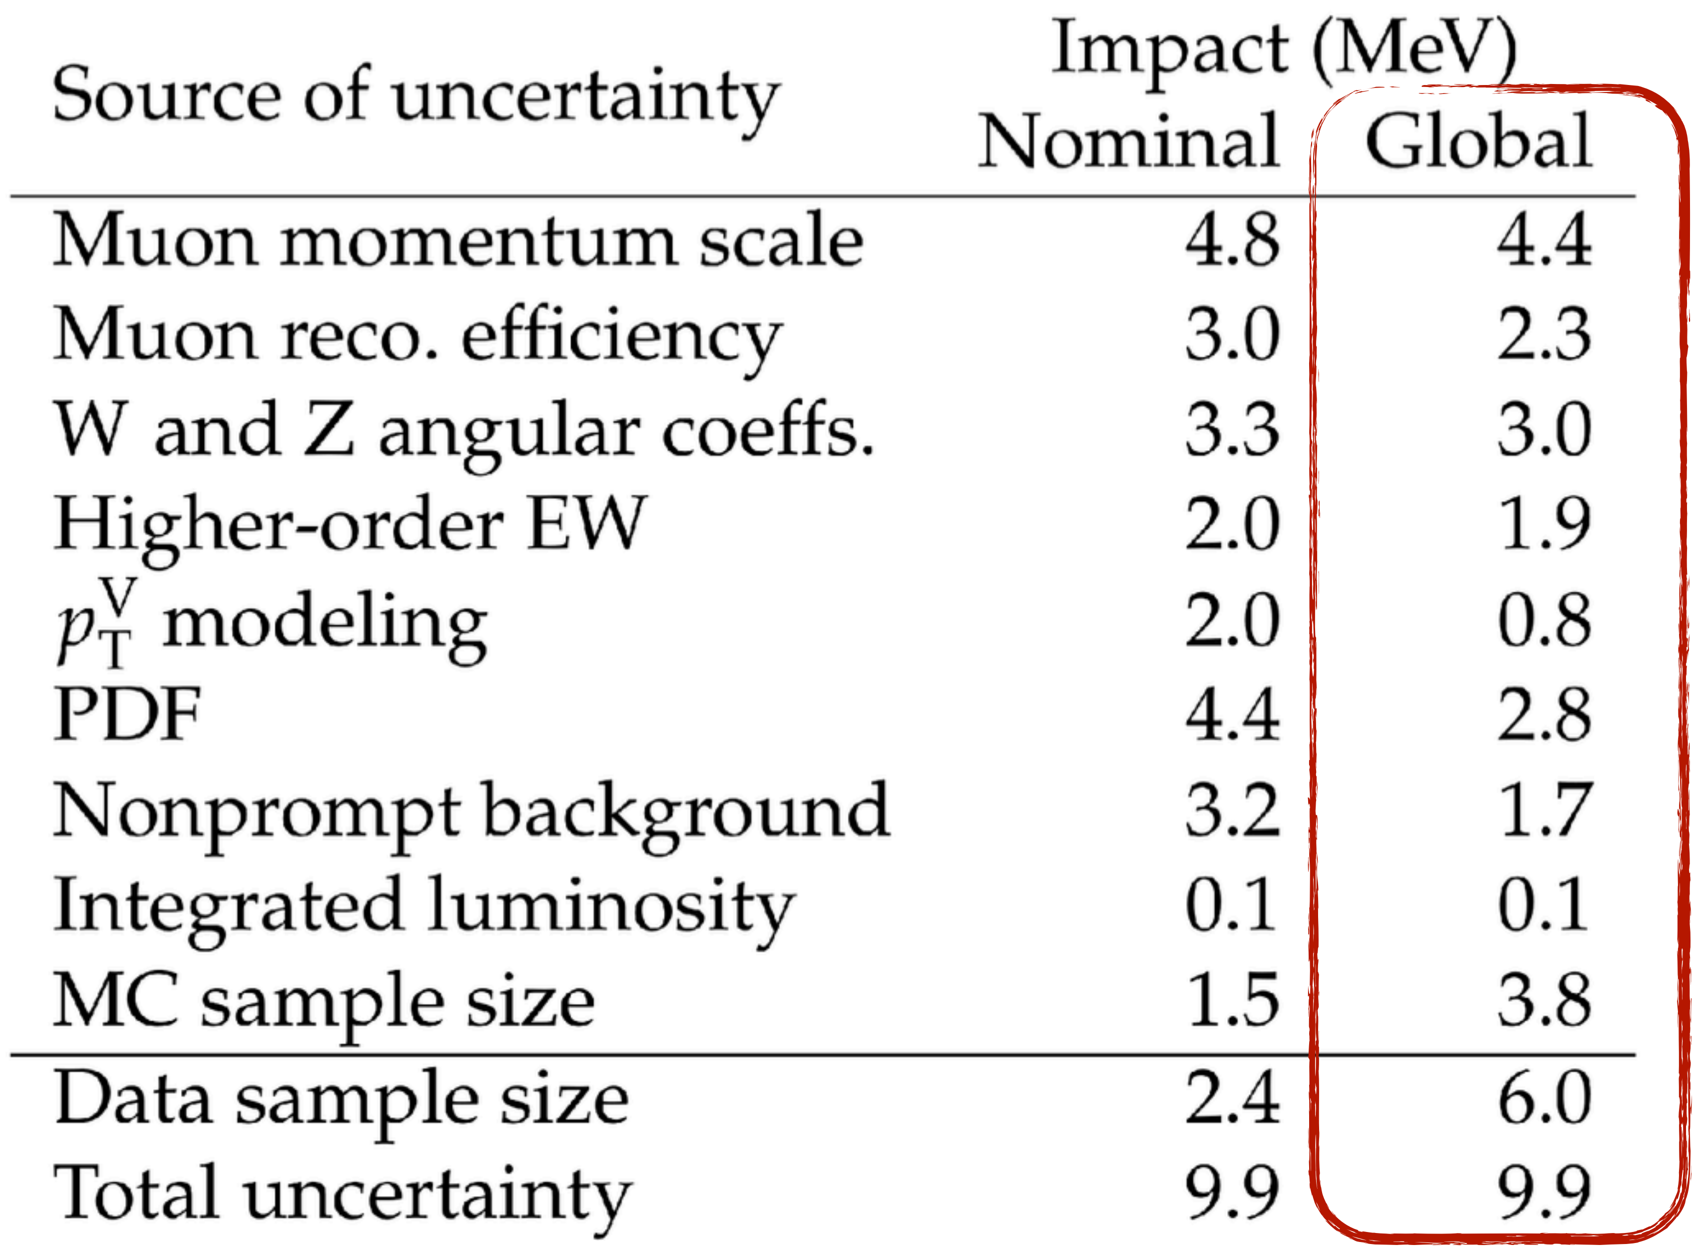
Compared to ATLAS

- Leverage larger data set while managing comparable exp. uncertainties in high PU
- Stronger constraints on PDFs
- Reduced impact of other theory
  - ATLAS EW unc. due to use of older Photos++
- Total calibration + muon eff. only 10% better
  - but Z-independent, model-based

CDF has advantages from pp, l̄ower E, PU

  - PDFs better understood (valence quarks)
  - Less hadronic activity (simpler recoil calibration)
  - Low tracking material aids lepton calibration

➡Much larger data set is the CMS saving grace



Source of uncertainty	Impact (MeV)	
	Nominal	Global

CMS

The CMS precision measurement program and the electroweak fit

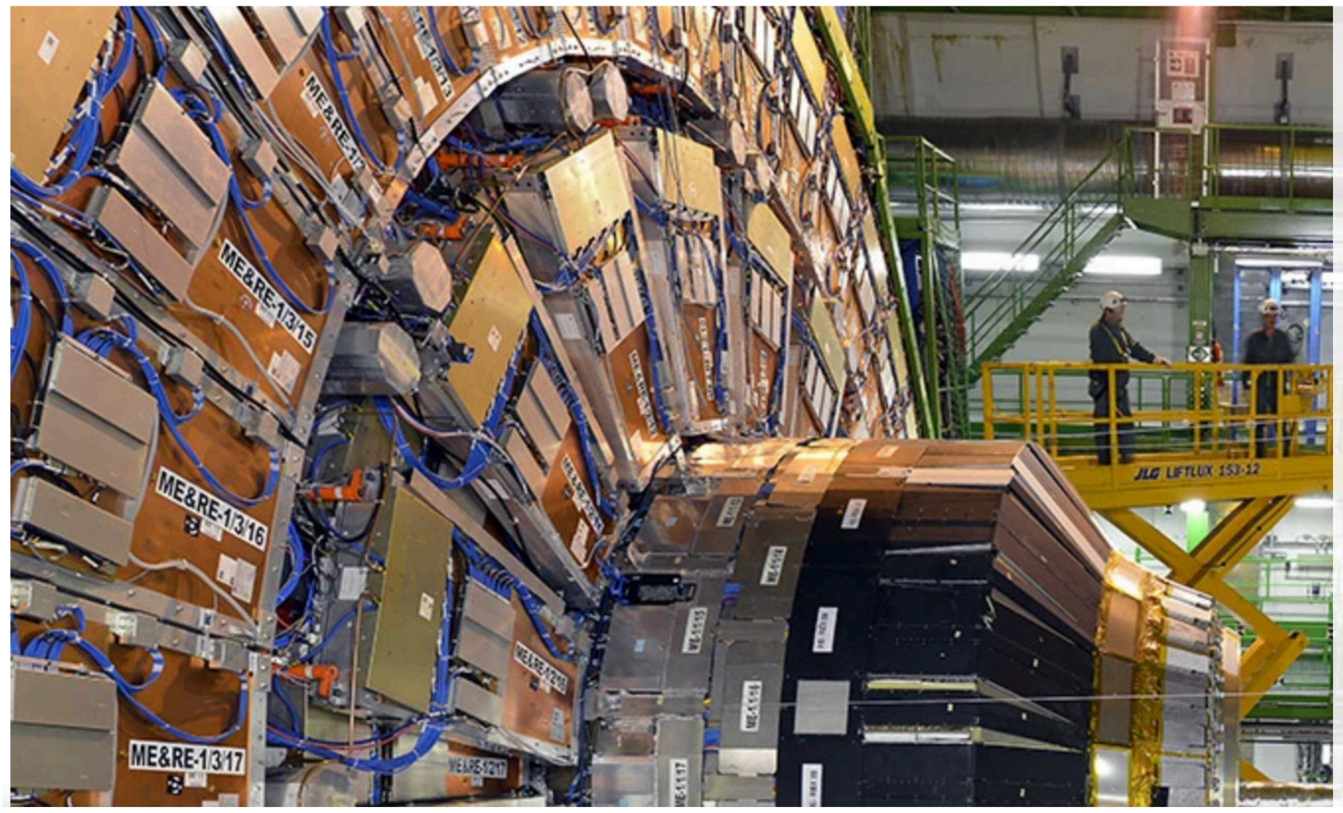
Summary and conclusions

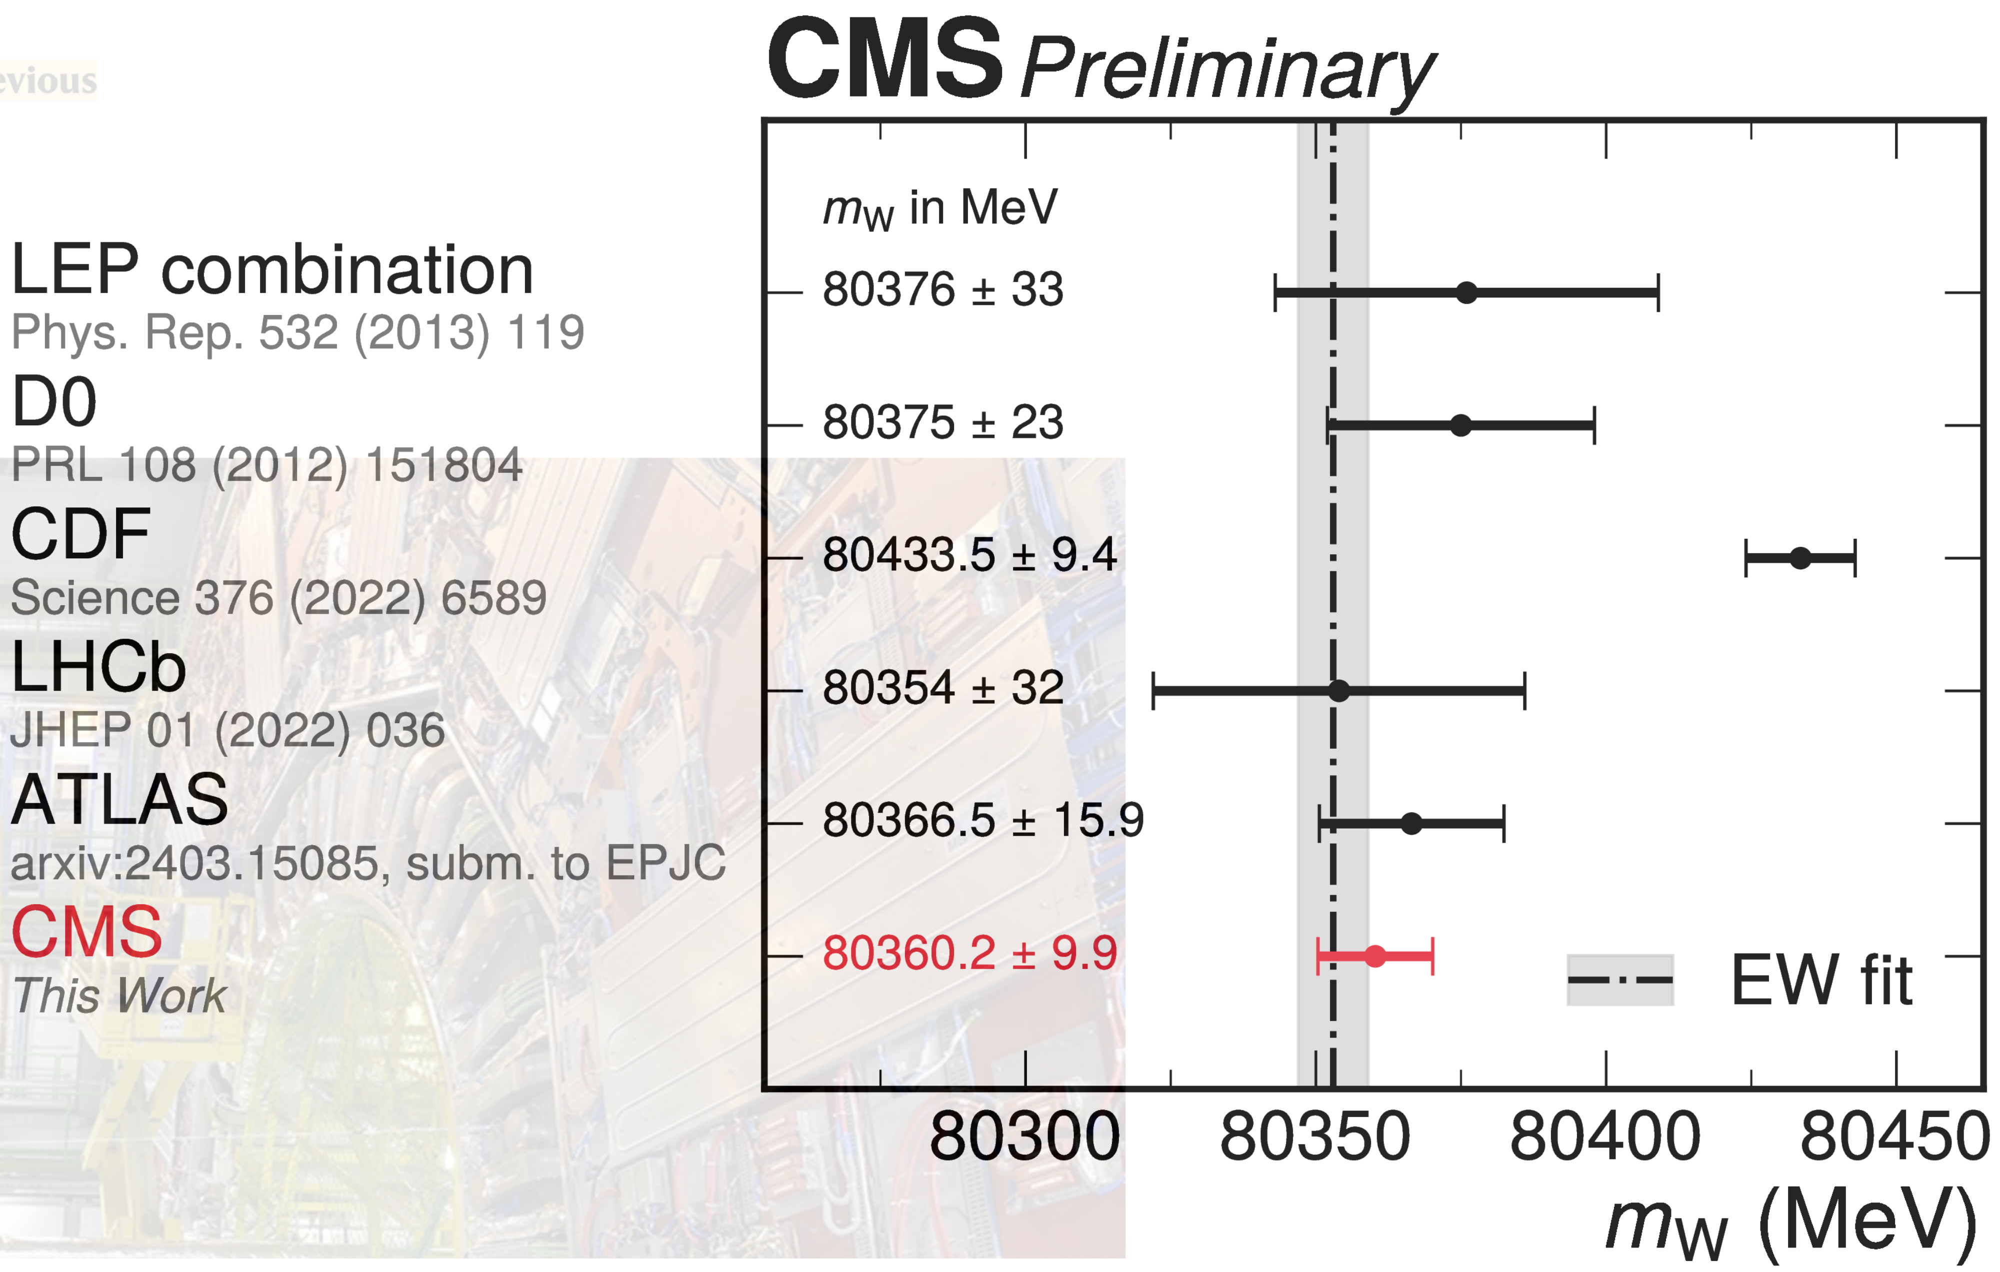
- The first m_W measurement at CMS is a long-awaited milestone for precision physics at the LHC
  - Documented in CMS-PAS-SMP-23-002, submission to journal very shortly
  - Most precise measurement at LHC
  - In tension with CDF measurement
- The CMS detector and the LHC are precision instruments, far exceeding expectations

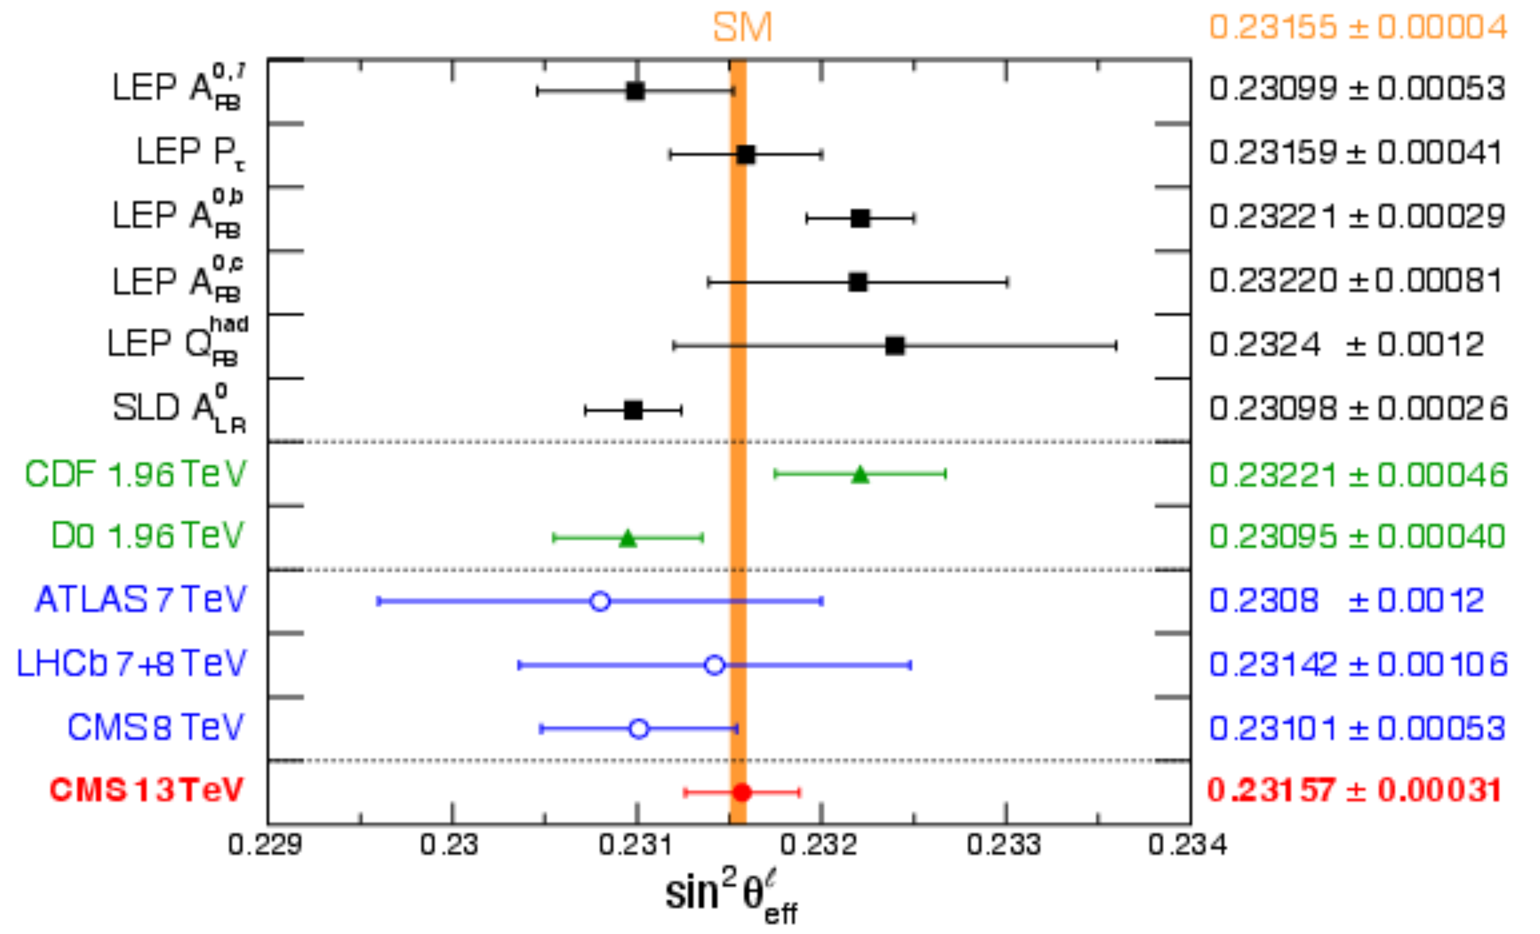
'The standard model is not dead': ultra-precise particle measurement thrills physicists

CERN's calculation of the *W* boson's mass agrees with theory, contradicting a previous anomaly that had raised the possibility of new physics.

By Elizabeth Gibney



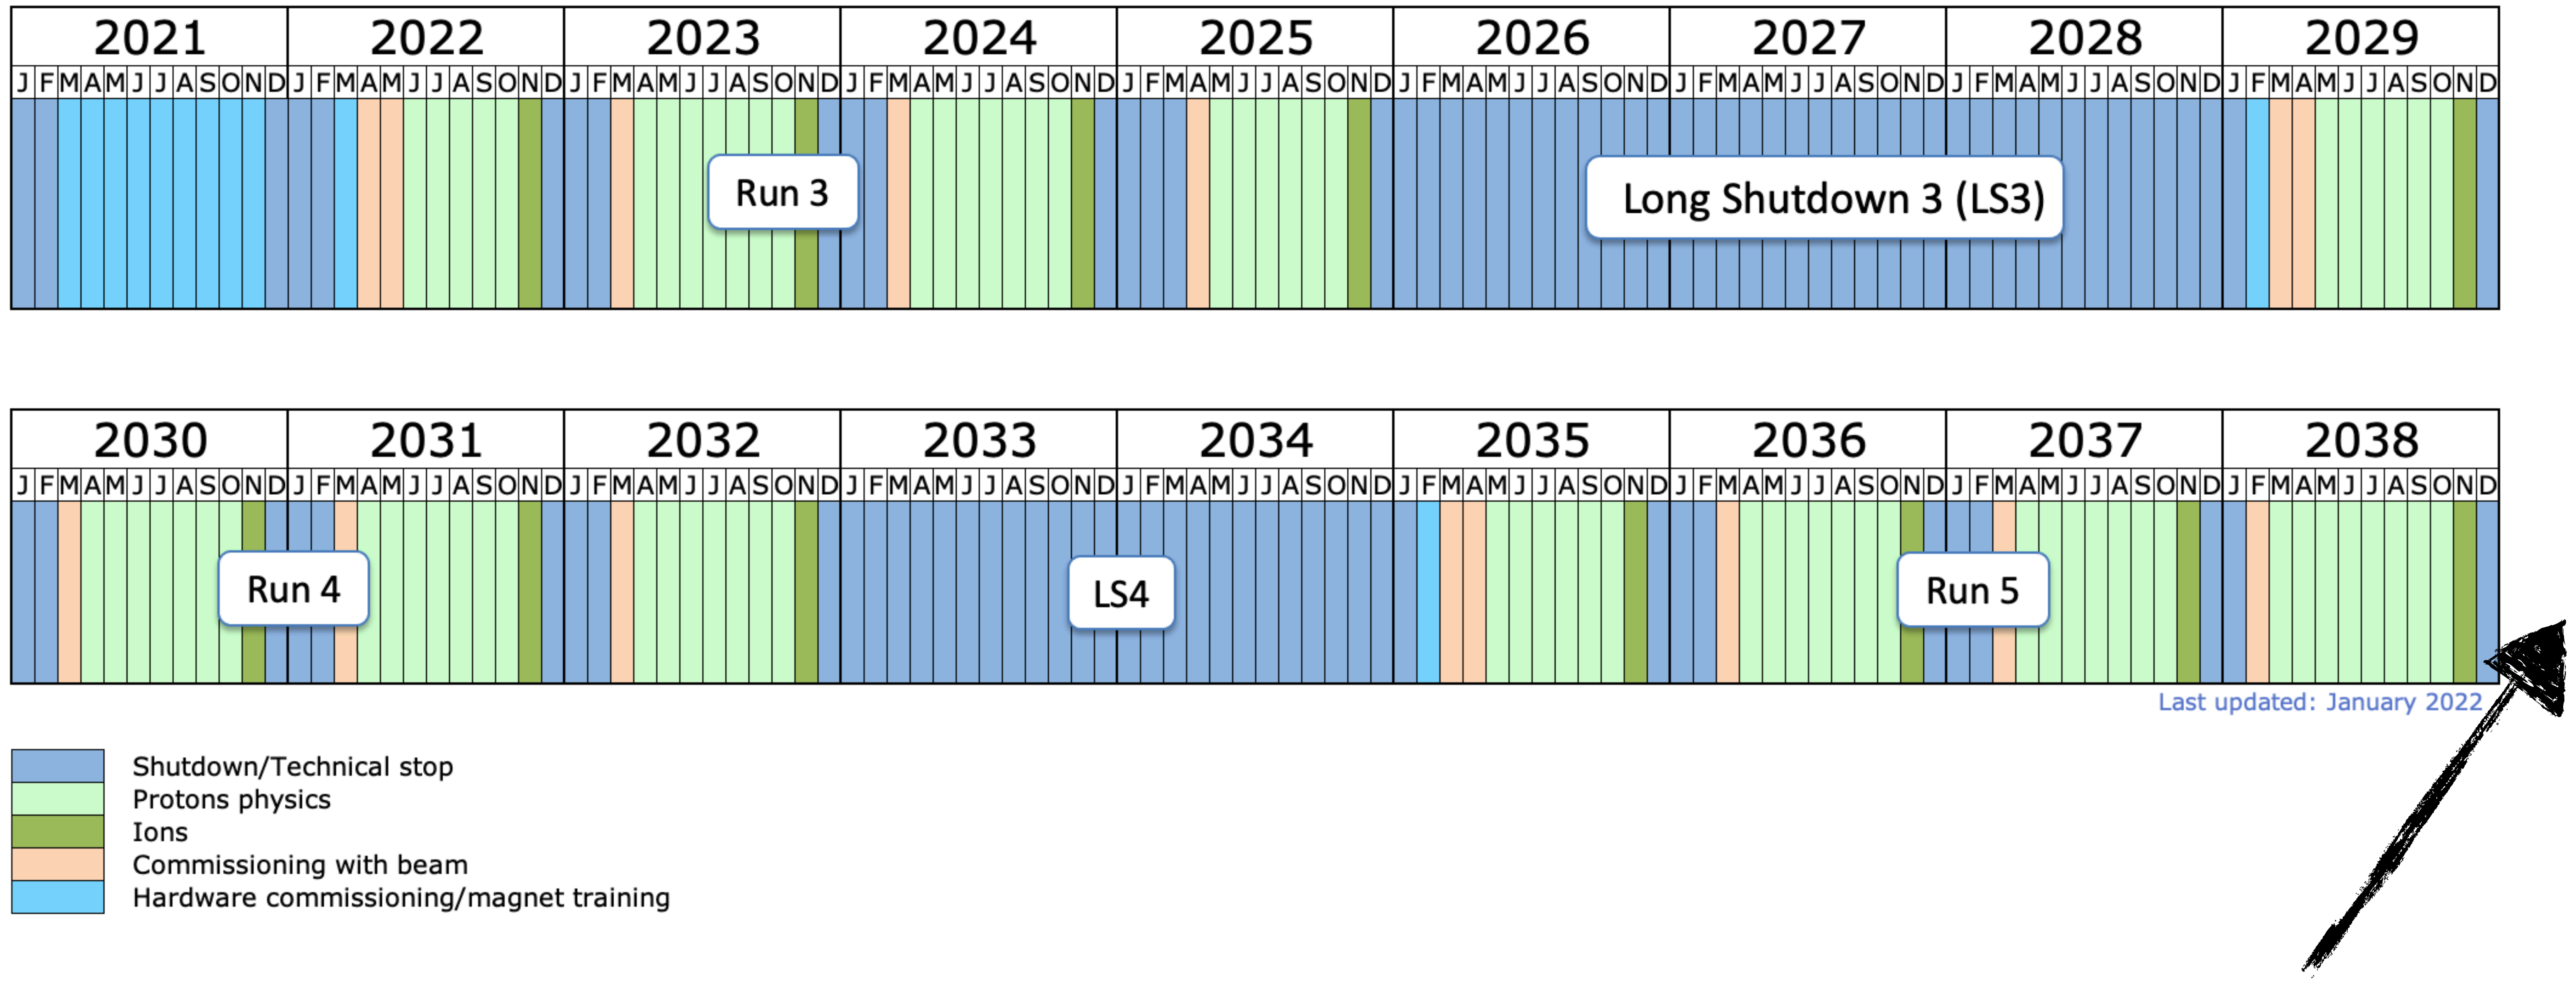




Backup

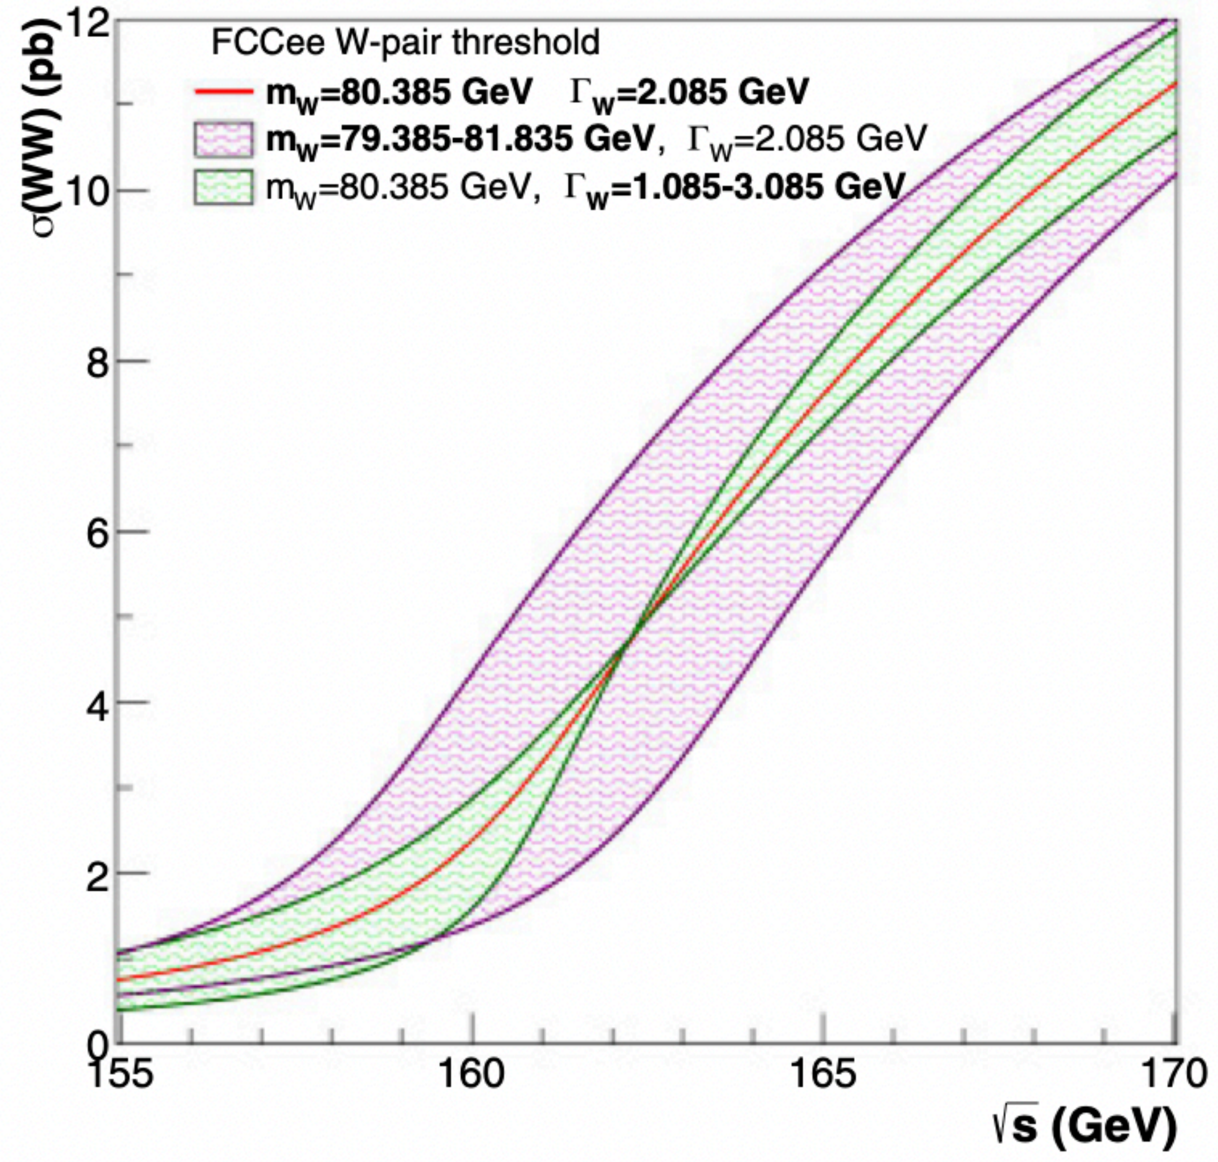
Looking forward

- In the near (and not so near) future, **hadron colliders are our main probe of m_W**
  - Can envision huge theoretical progress in next 20 years
  - Enormous data set will come with increased experimental challenges due to high-pileup and detector aging
  - Mitigate with special runs, detector upgrades, reconstruction advancements



- Future e^+e^- collider provides more direct, less theory-dependent measurement from threshold scans
  - FCC-ee anticipates < 1 MeV unc. in m_W

FCC-ee?

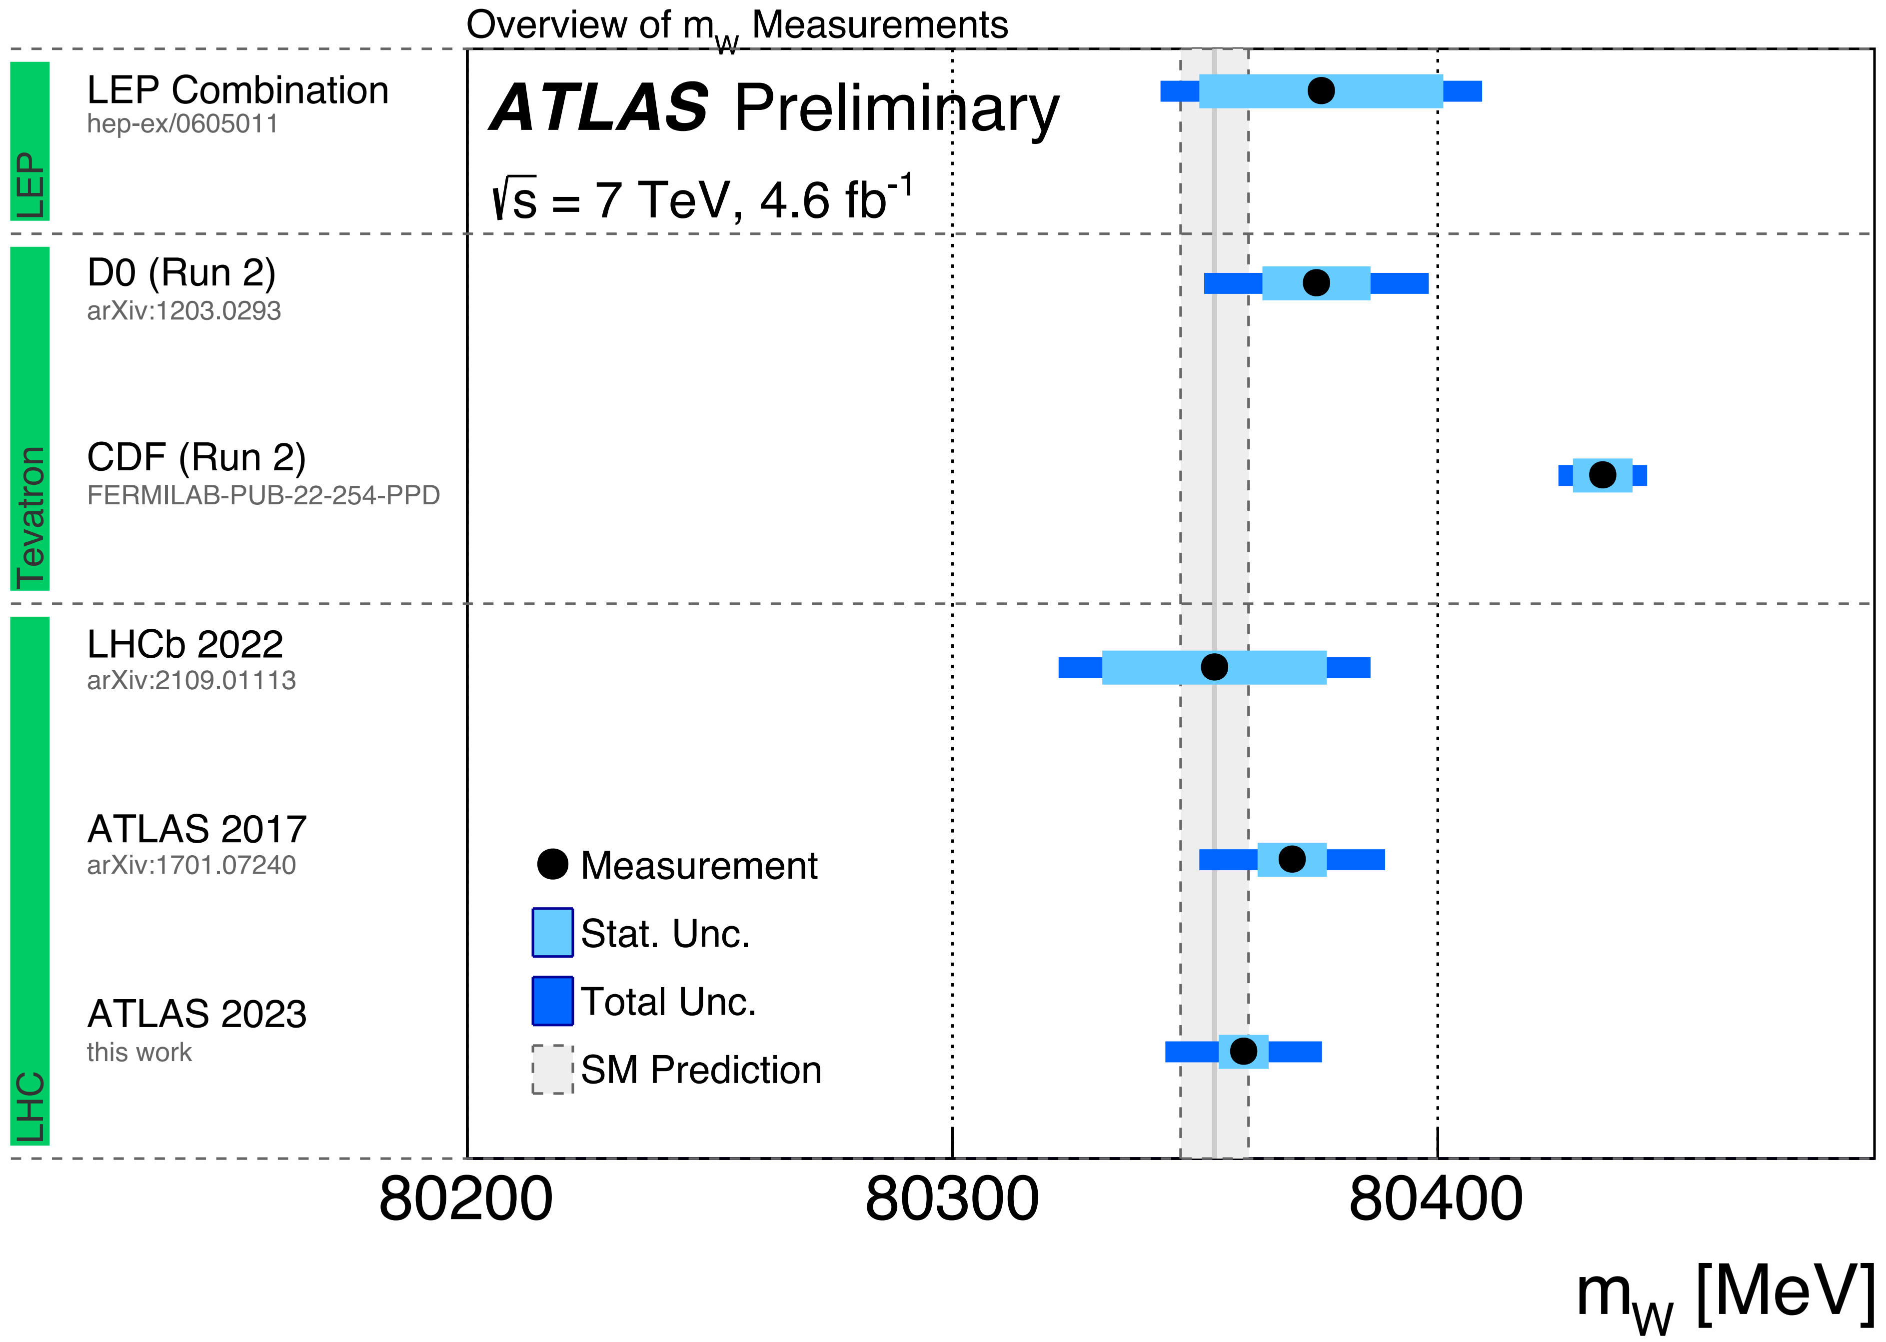


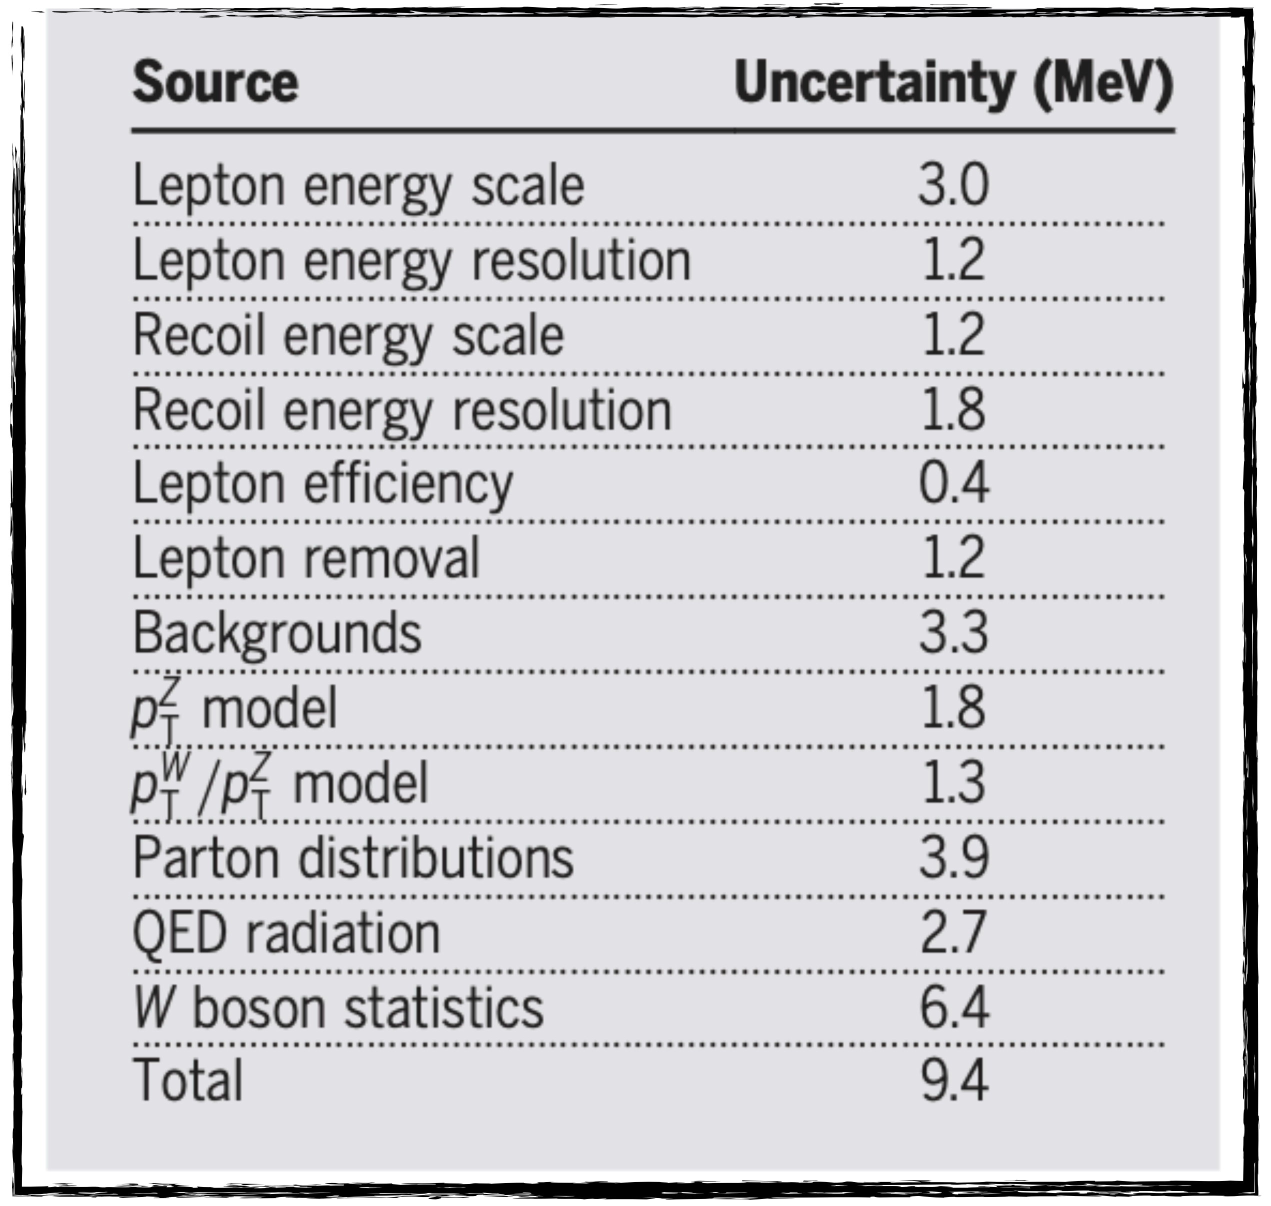
https://doi.org/10.1140/epjst/e2019-900045-4

- Experimental+theory hadron collider communities must meet the challenge of providing results that stand the test of time
- Publish/maintain analyses that can be reinterpreted with improved theory

m_W measurements: current landscape

- LEP combination (2013): 33 MeV unc.
  - Semi-leptonic and fully hadronic WW decays
- Tevatron (proton-antiproton):
  - wrt LHC: Smaller W production uncertainty, better estimation of neutrino momentum
  - D0 (2013): (23 MeV unc.)
  - CDF (2022): (9.4 MeV unc.)
    - $m_T + p_T^\ell$ (e+μ); very precise ℓ calibration; 4.2 M events
- LHCb (2021) (32 MeV unc.)
  - 13 TeV, p_T^μ channel only; 2.4 M events
- ATLAS (15.9 MeV unc.)
  - Published 2017, updated earlier this year
  - 7 TeV data, $m_T + p_T^\ell$ (e+μ, 3 η categories); 14 M events
  - Driven by p_T^ℓ channel (~90%)
- CMS (9.9 MeV unc.)
  - 13 TeV data, p_T^ℓ (μ only, 48 η categories); 100 M events





Source	Uncertainty (MeV)
Lepton energy scale	3.0
Lepton energy resolution	1.2
Recoil energy scale	1.2
Recoil energy resolution	1.8
Lepton efficiency	0.4
Lepton removal	1.2
Backgrounds	3.3

CDF uncertainty breakdown

Comparison of measurements (previous ATLAS)

	ATLAS	LHCb	CDF
Collider	pp	pp	$p\bar{p}$
$\sqrt{s}$	7	13	1.96
$\mathcal{L}$	4.1–4.6	1.7	8.8
$N_{pileup} \sim$	9	2	3
Final states	e/μ	μ	e/μ
Fit variables	m_T, p_T^ℓ	q/p_T^ℓ, p_T^{miss}	m_T, p_T^ℓ, p_T^{miss}
$p_T^\ell >$ (GeV)	30	28	30
$p_T^\ell <$ (GeV)	50	52	55
$\eta^\ell >$	-2.5	2.2	-1.0
$\eta^\ell <$	2.5	4.4	1.0
$p_T^{miss} >$ (GeV)	30	N/A	30
$m_T >$ (GeV)	60	N/A	60
$m_T <$ (GeV)	100	N/A	100
$u_T <$ (GeV)	15	N/A	15
Selected events $\sim$	13.7M	2.4M	4.2M
MC generator	POWHEG-PYTHIA 8	POWHEG-PYTHIA 8	RESBOS
PDF set	NNPDF3.0	NNPDF3.1	NNPDF3.1

Comparison of uncertainties (previous ATLAS)

Source	ATLAS (MeV)	LHCb (MeV)	CDF (MeV)
Lepton uncertainties	9.2	10	3.5
Recoil energy scale & resolution	2.9	N/A	2.2
Backgrounds	4.5	2	3.3
Model theoretical uncertainties	9.9	17	3.5
PDFs	9.2	9	3.9
Statistical	6.8	23	6.4
Total	18.5	32	9.4

Theory nuisance parameters

- Level 1: At given order vary parameters around their known values

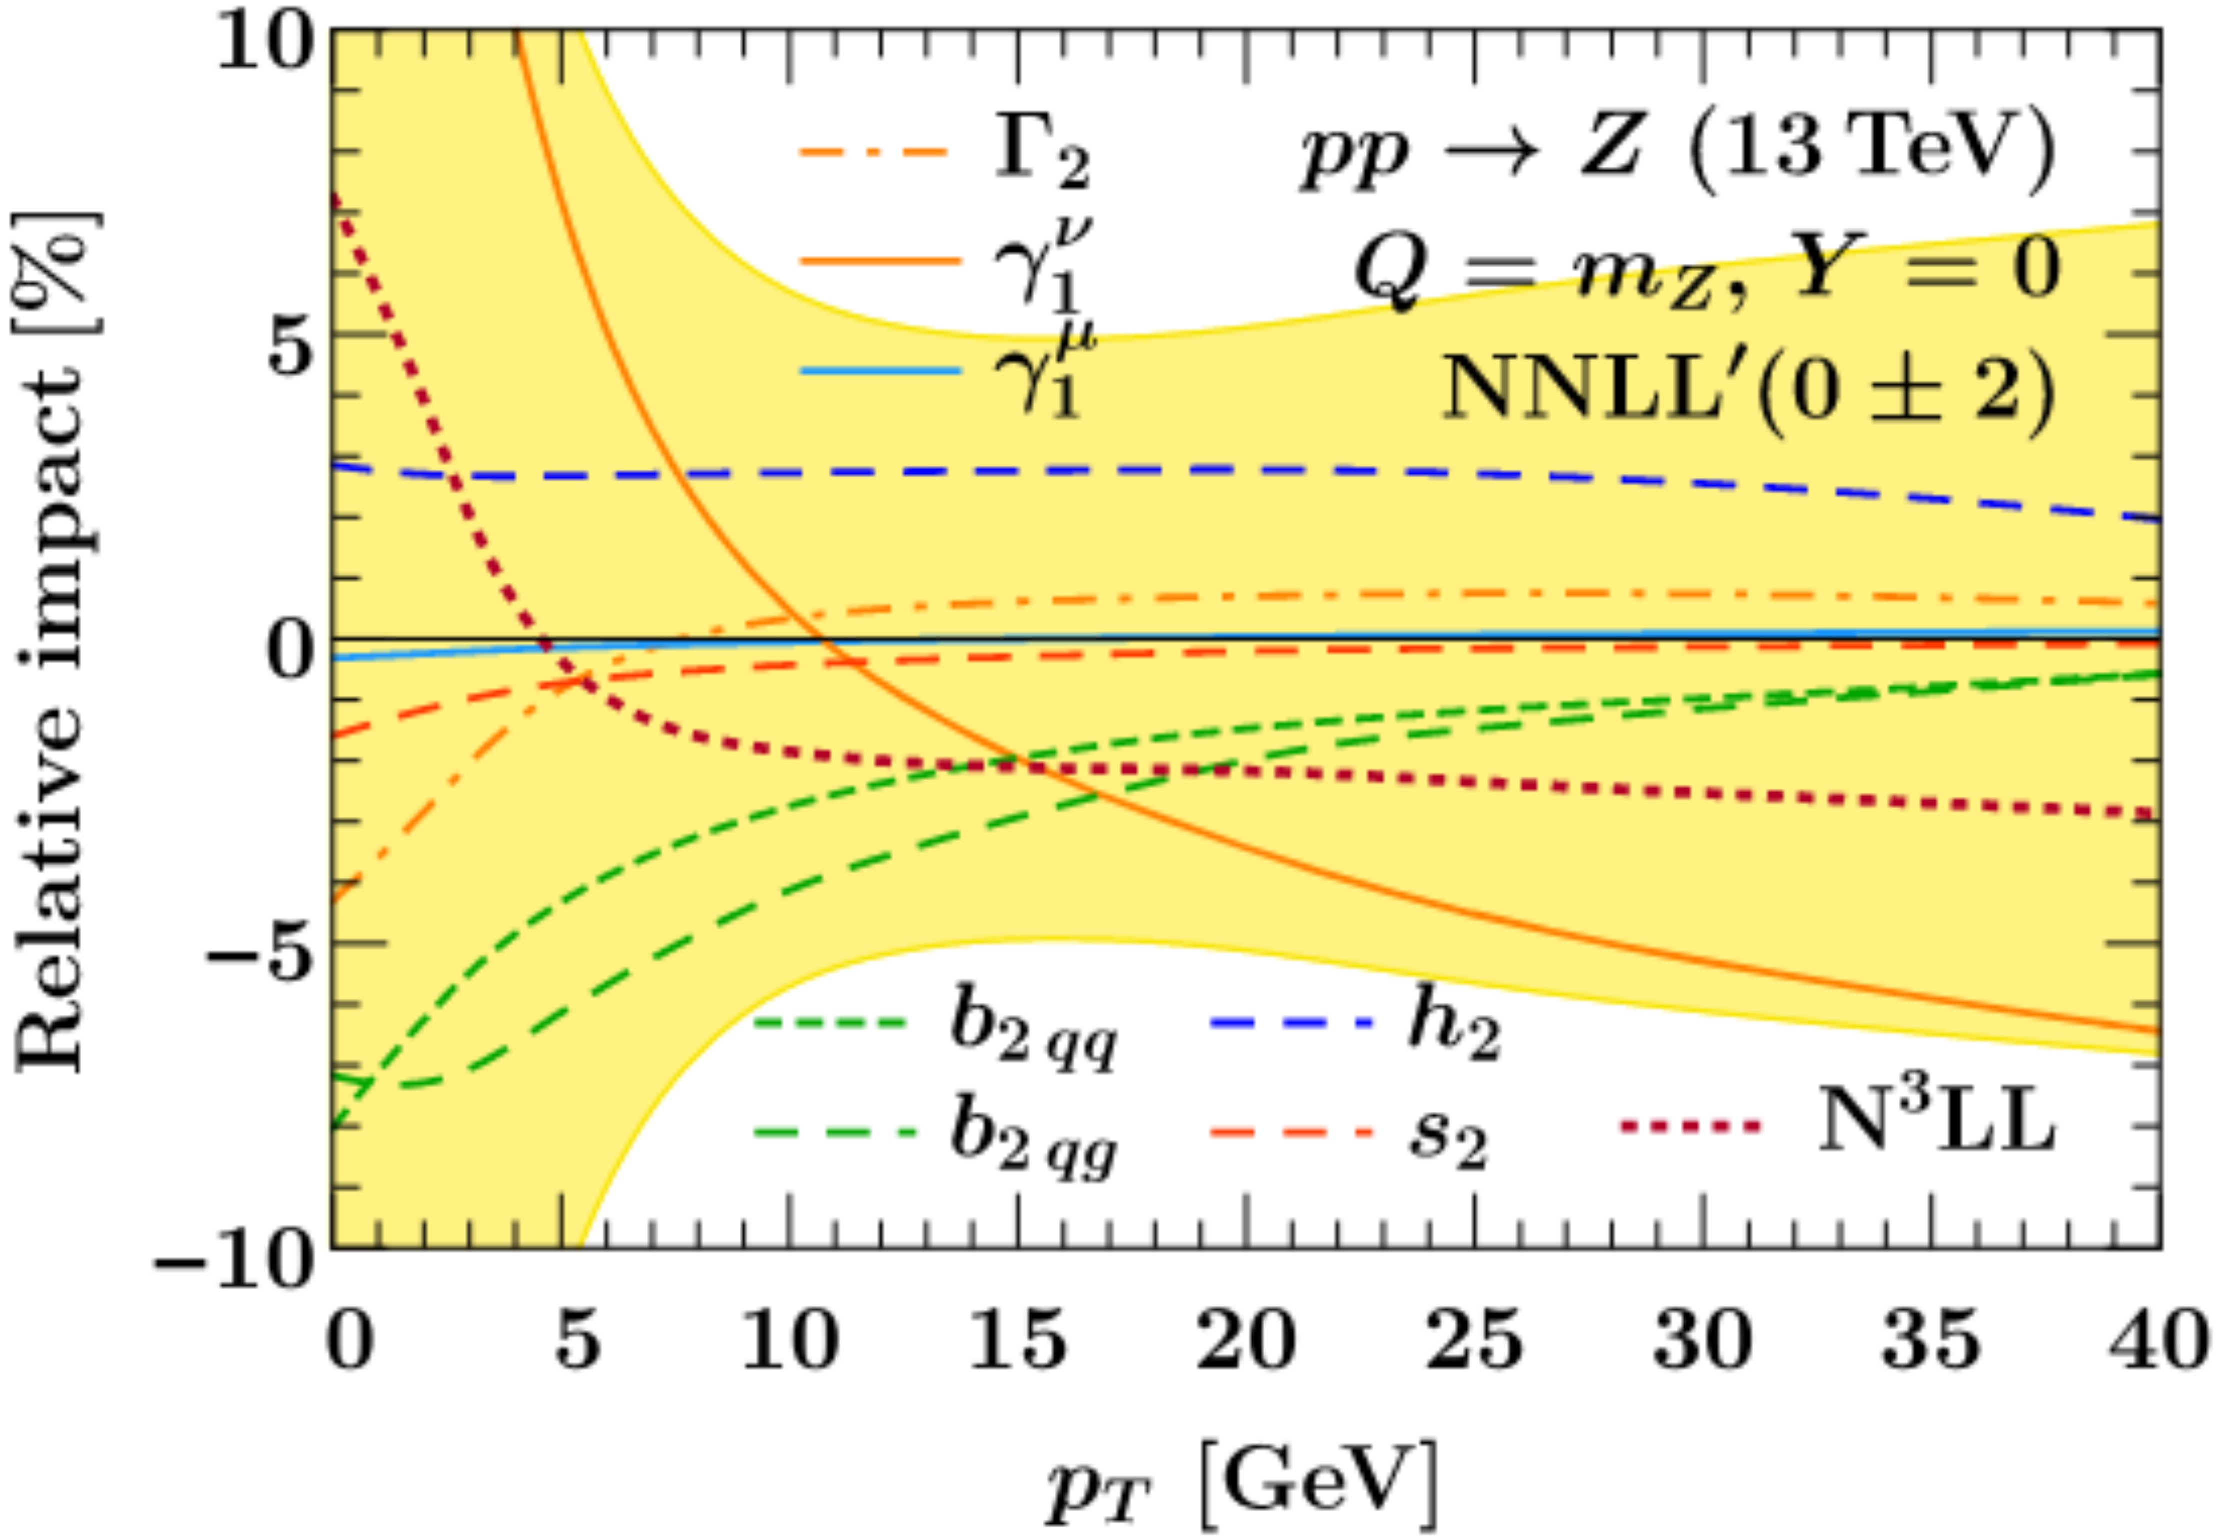
  $$c_0 + \alpha_s(\mu)\left[c_1 + \alpha_s(\mu)\, c_2 + \cdots\right] \to c_0 + \alpha_s(\mu)(c_1 + \tilde{\theta}_1)$$

  - Simpler but perhaps less robust

- Level 2: Implement the full next order in terms of unknown parameters

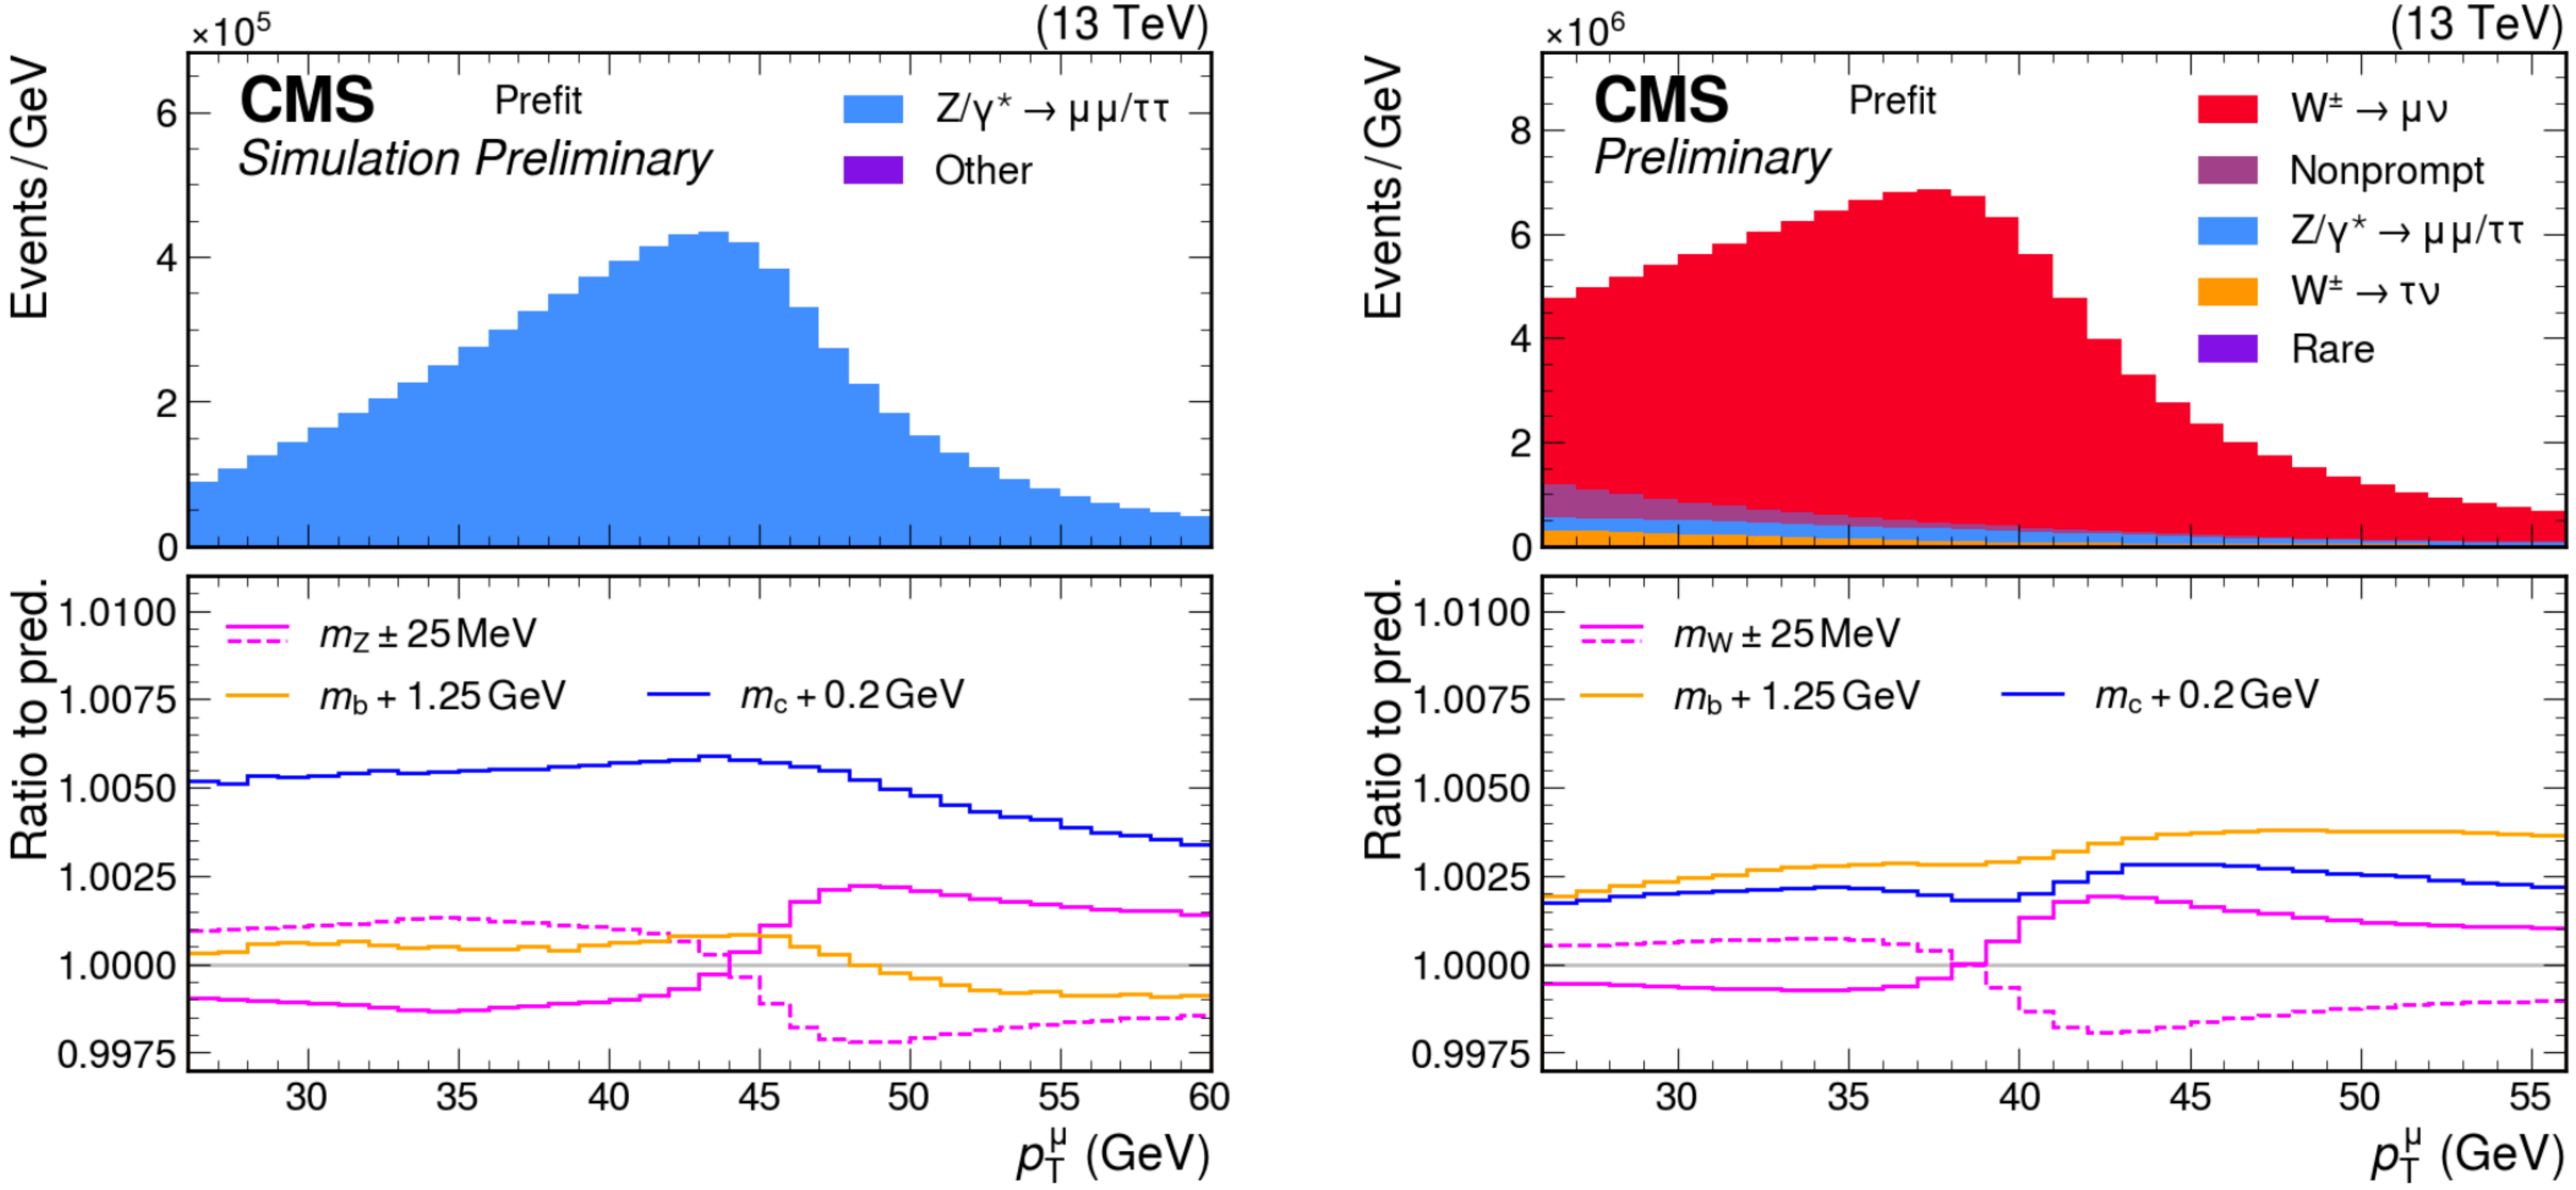
  $$c_0 + \alpha_s(\mu)\left[c_1 + \alpha_s(\mu)\, c_2 + \cdots\right] \to c_0 + \alpha_s(\mu)\left[c_1 + \alpha_s(\mu)\, \theta_2\right]$$

  - More involved, but also more robust, allowing for maximal precision



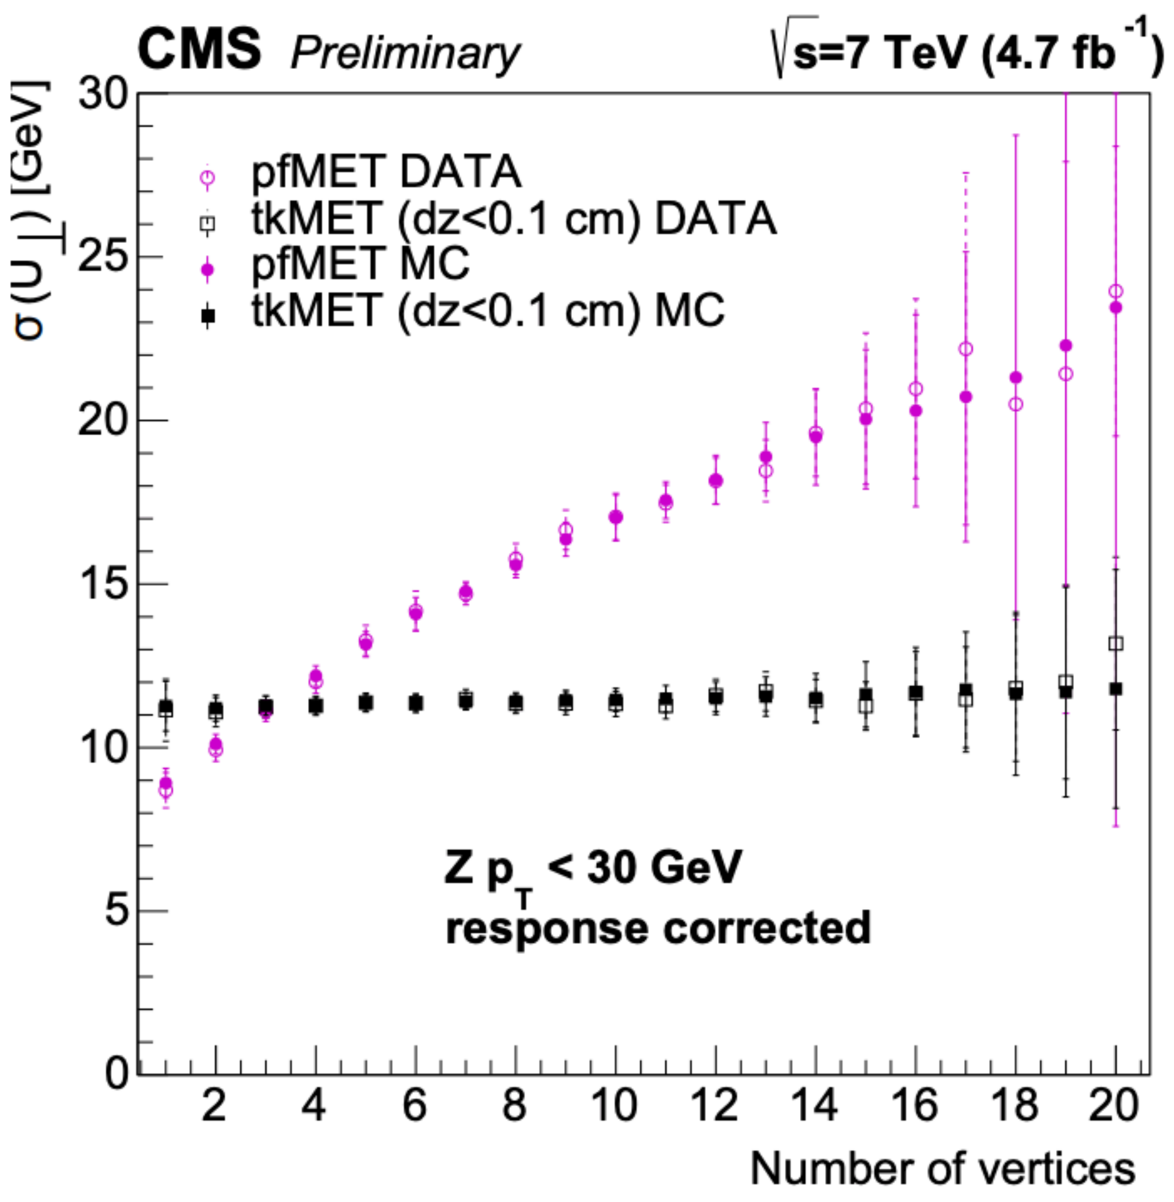
Heavy quark masses

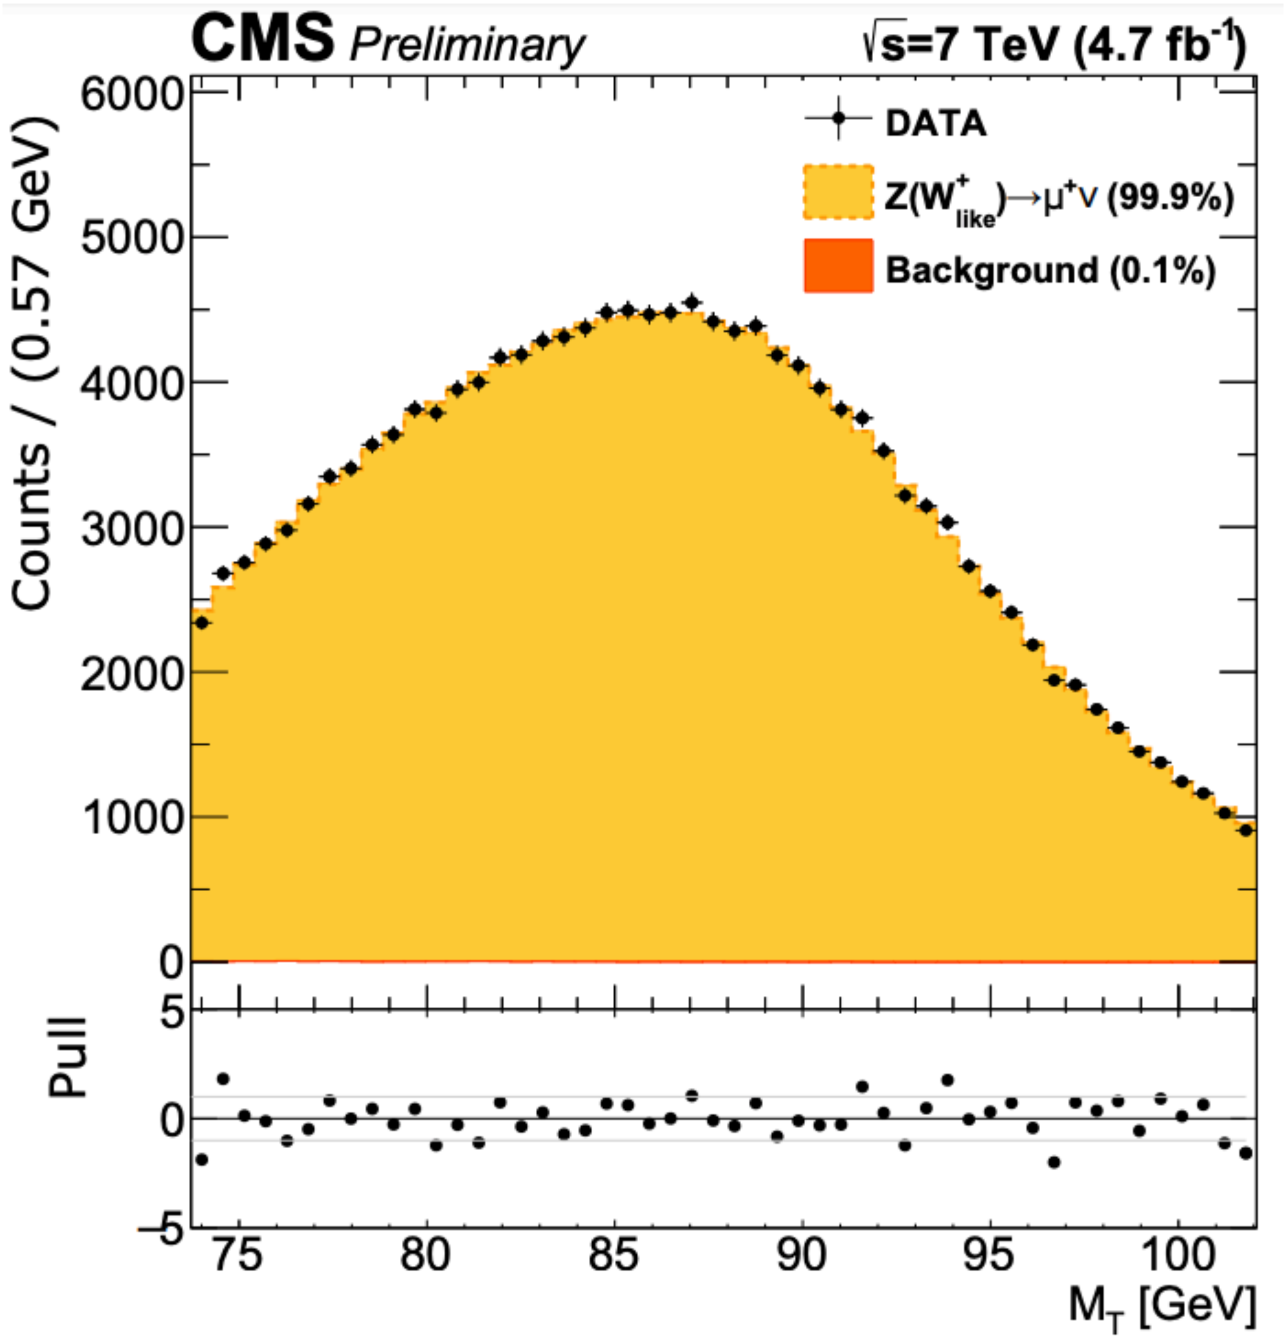
- Impact of quark mass thresholds estimated by varying quark mass thresholds in PDF (dedicated MSHT20 PDF sets)
  - **Impact ~0.7 MeV**

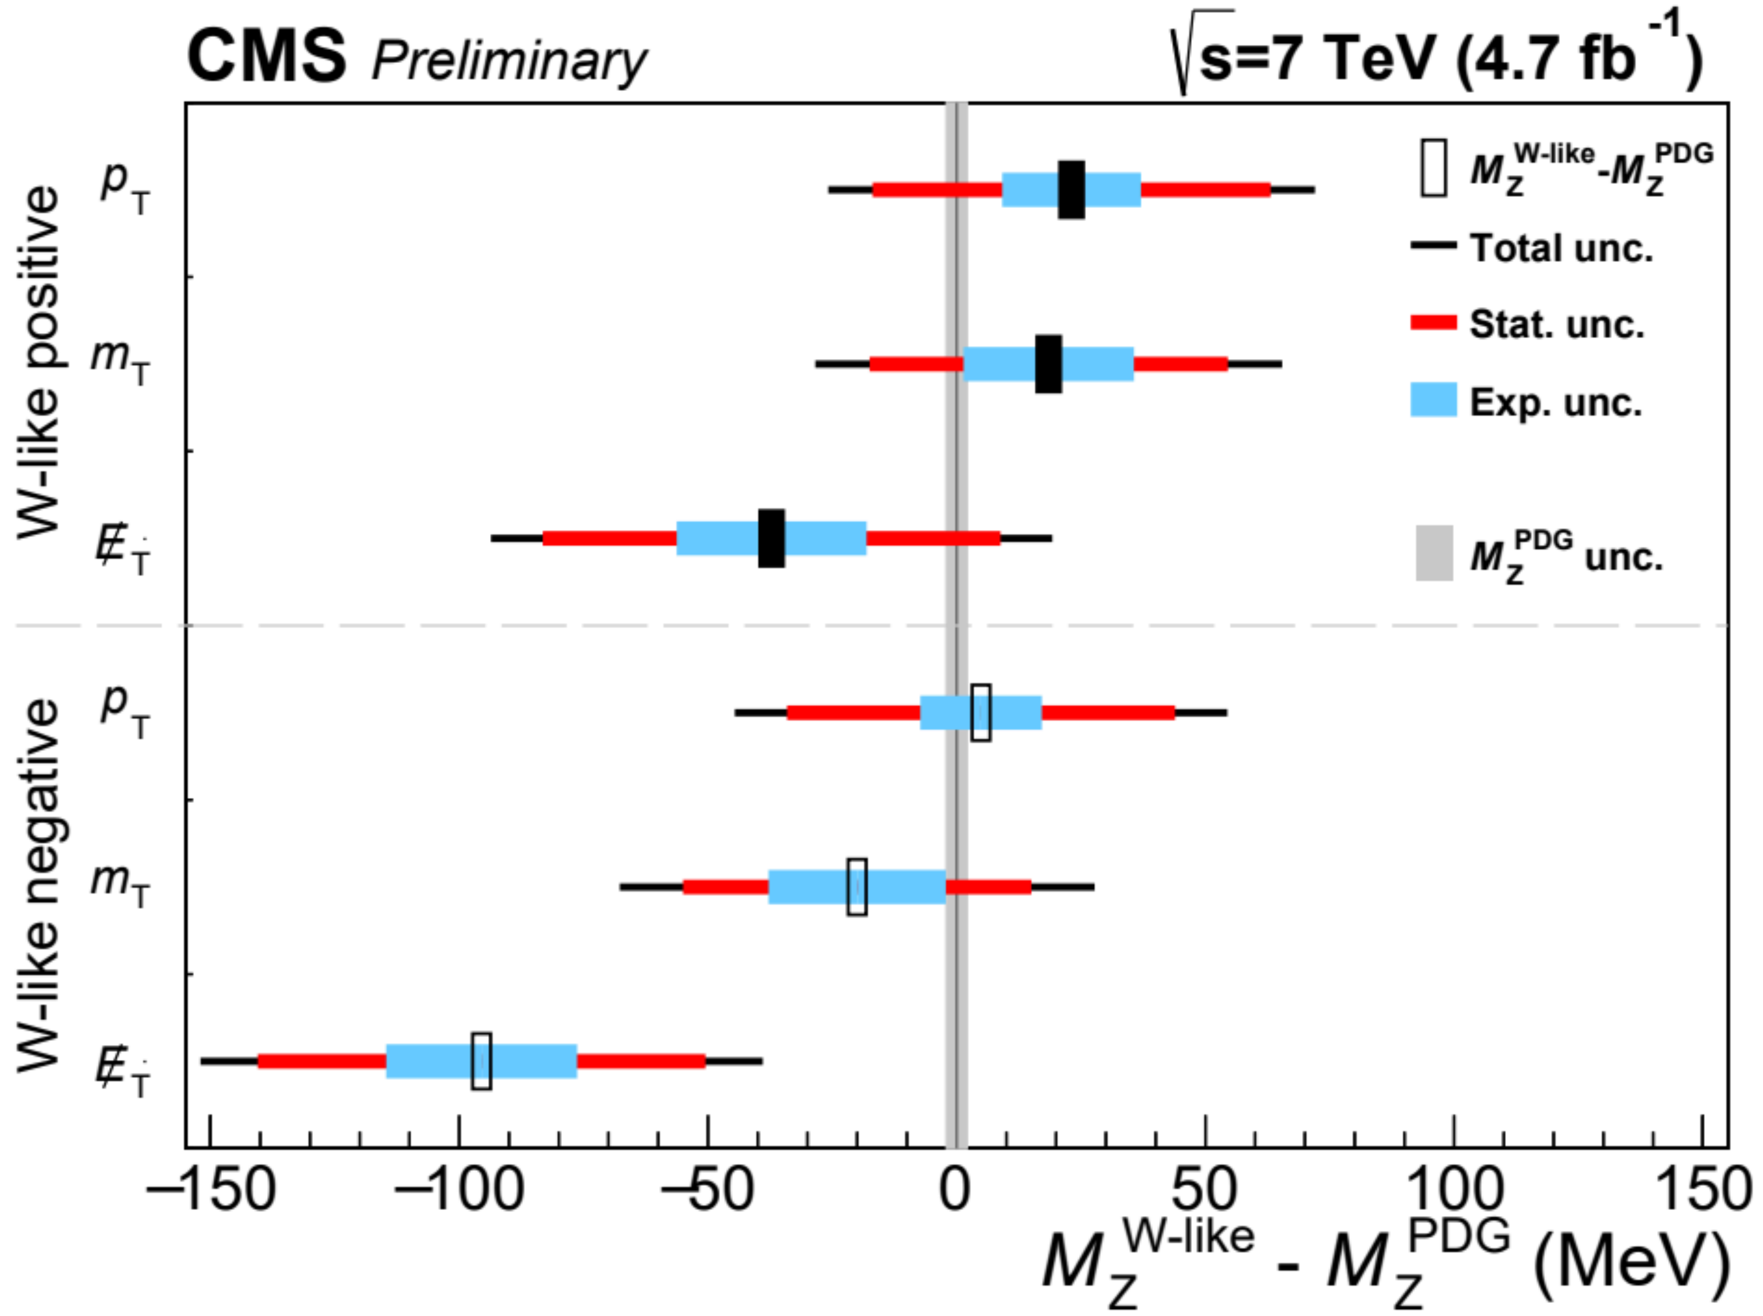


CMS W-like Z measurement

- Measurement of the Z mass in a “W-like” way: add one lepton to the p_T^{miss}
- First effort towards a W mass measurement
- Focued on calibration of muon momentum scale and recoil
  - **Limited to central muons**
- In principle, a demonstration that this is possible at CMS
- Combination of technical issues (MC production) and sociological ones (loss of person power) meant the effort stopped here



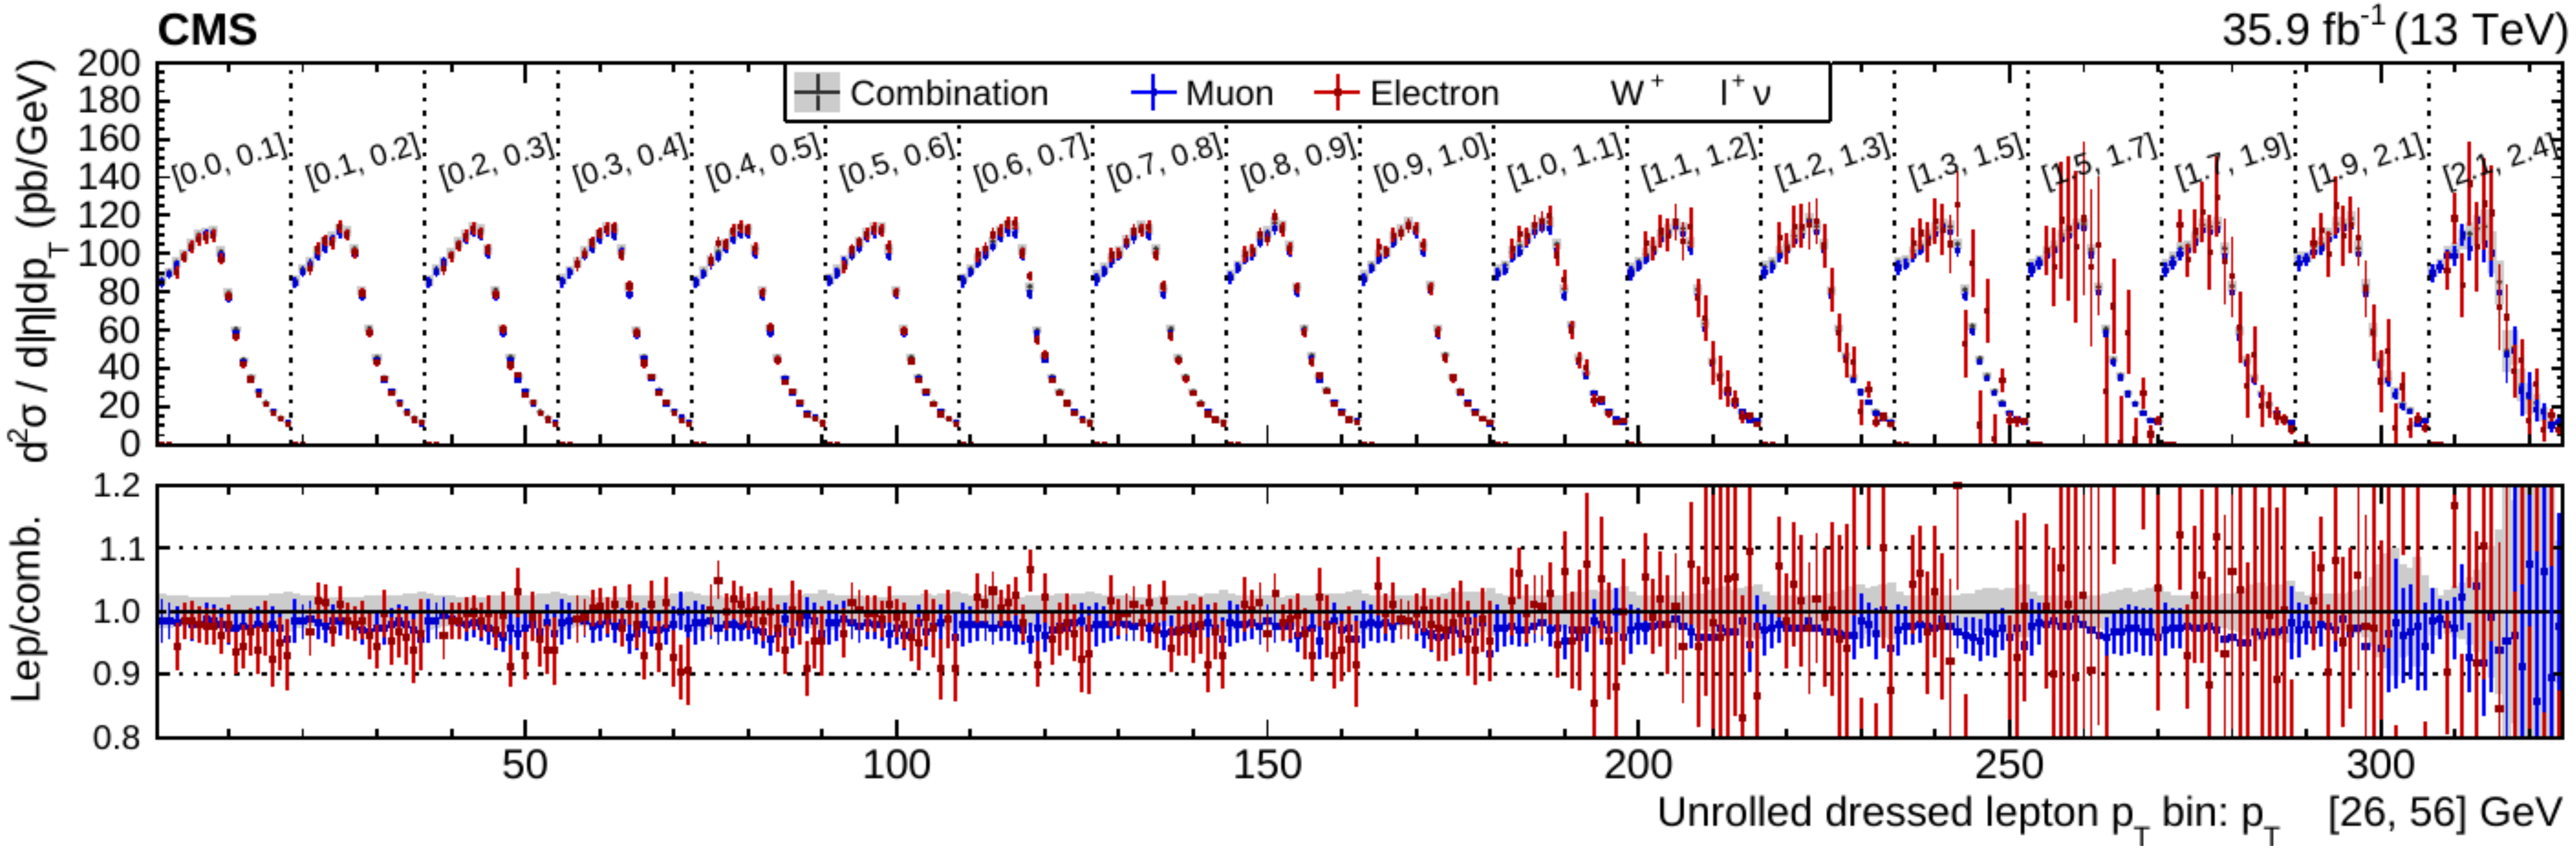




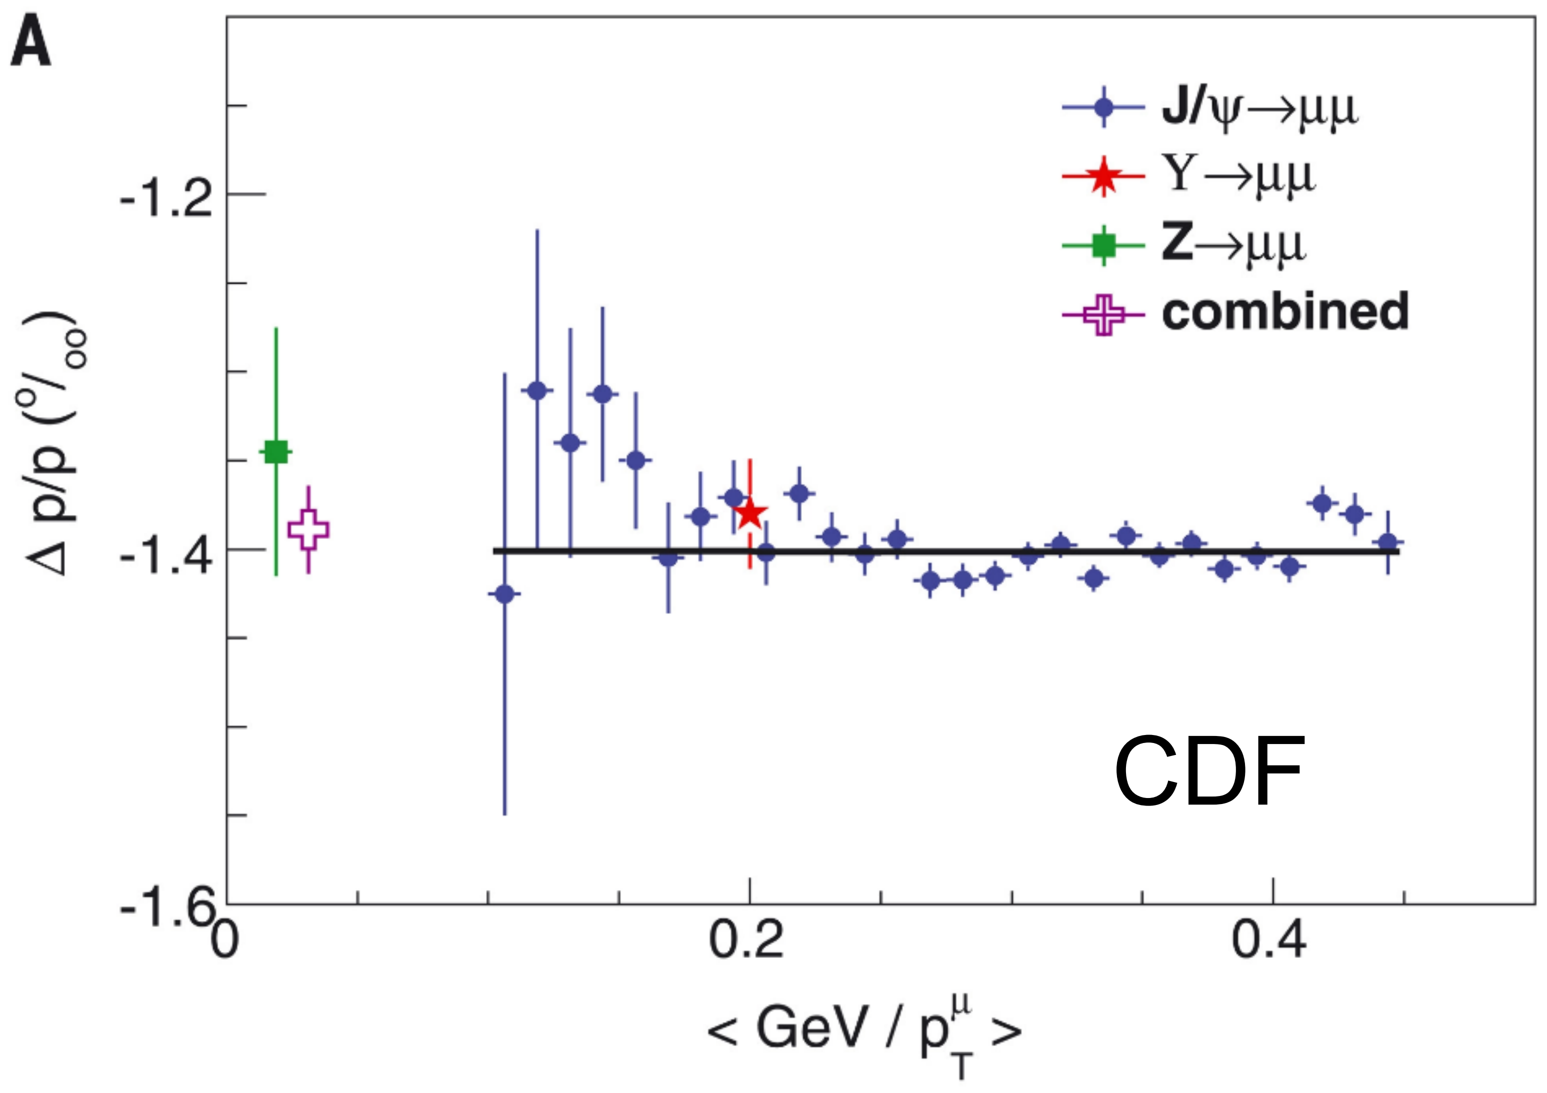
Electrons vs Muons

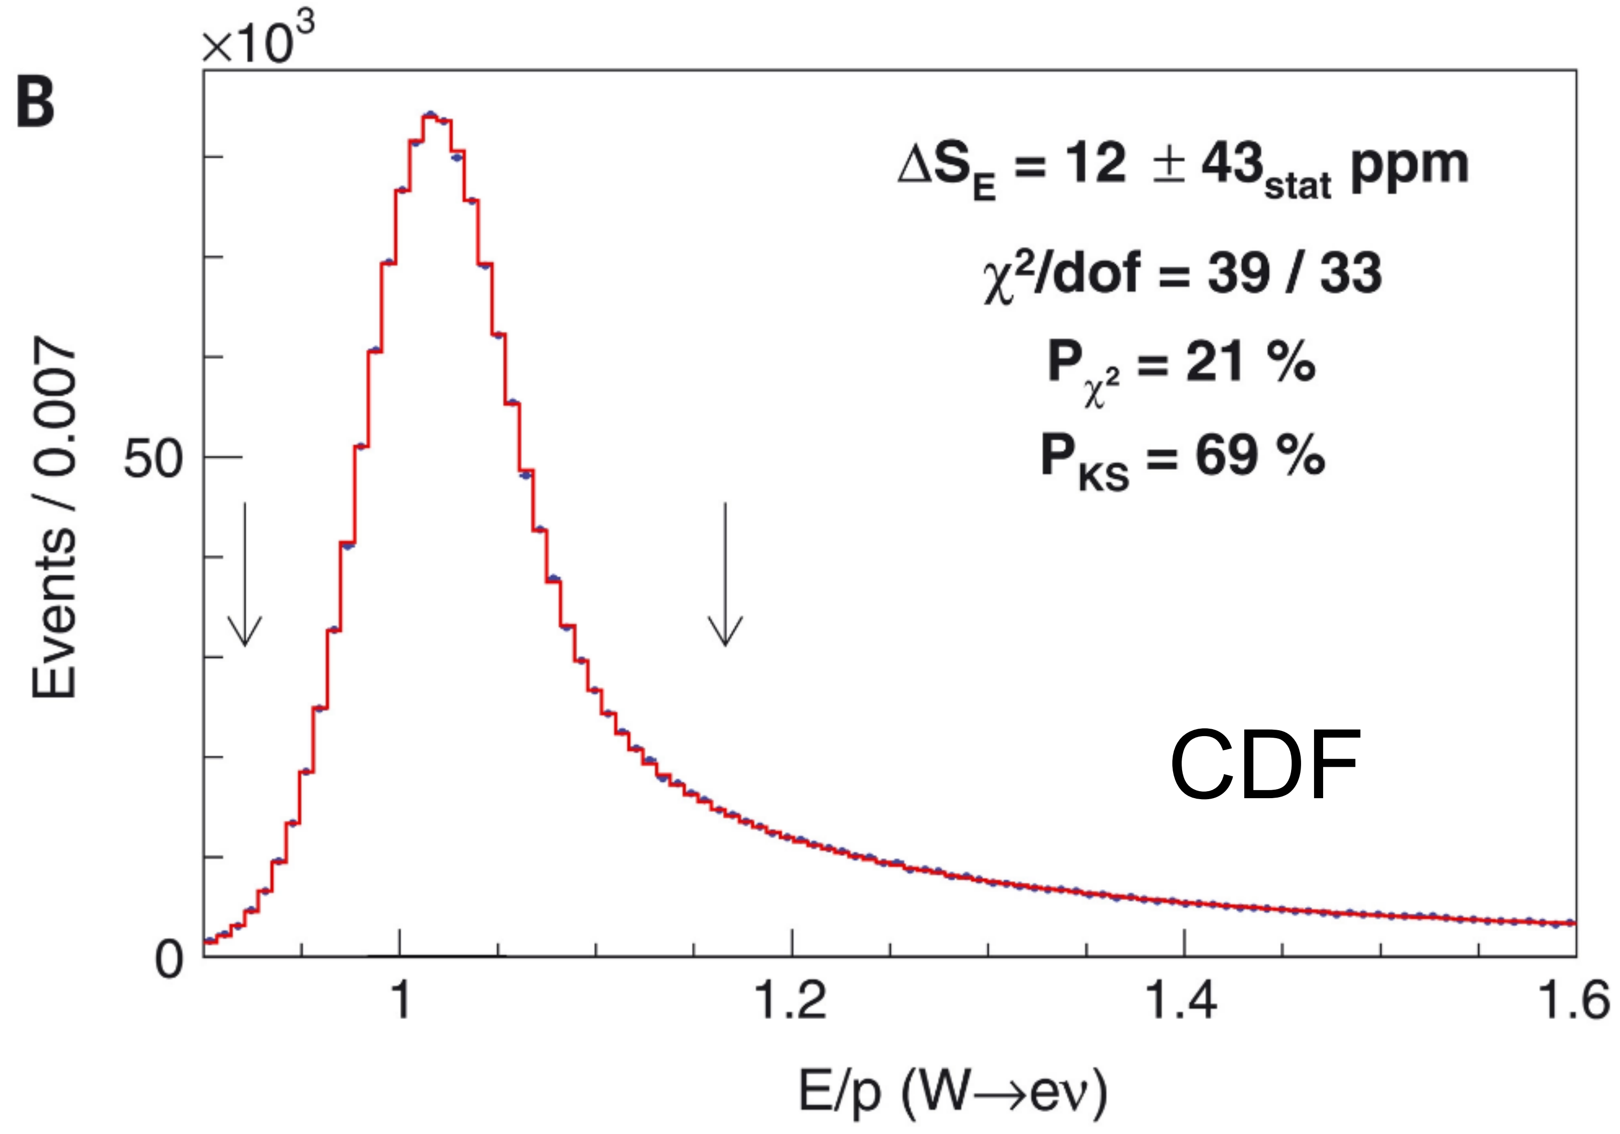
Phys. Rev. D 102 (2020) 092012

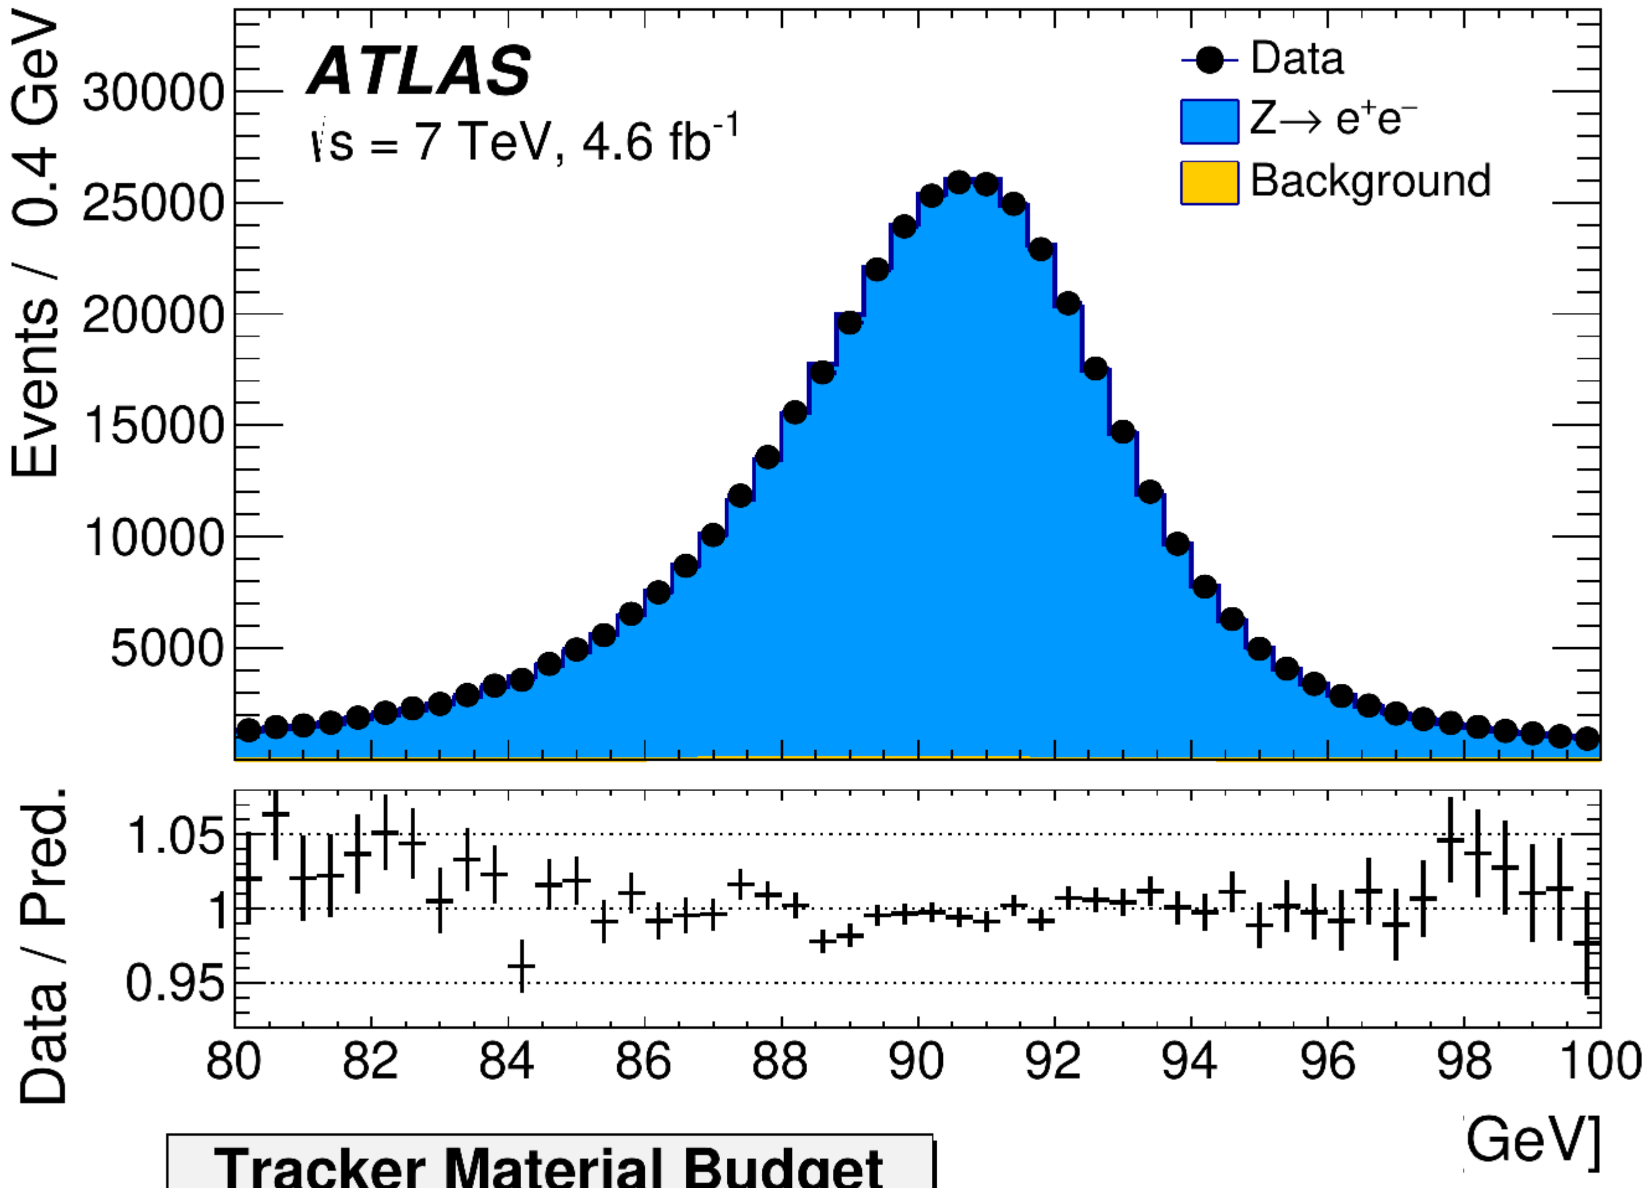
- Significantly larger statistical+experimental uncertainties for electrons already in W helicity measurement
- Energy calibration is also more challenging
- Will be difficult to be competitive with muons for mW measurements



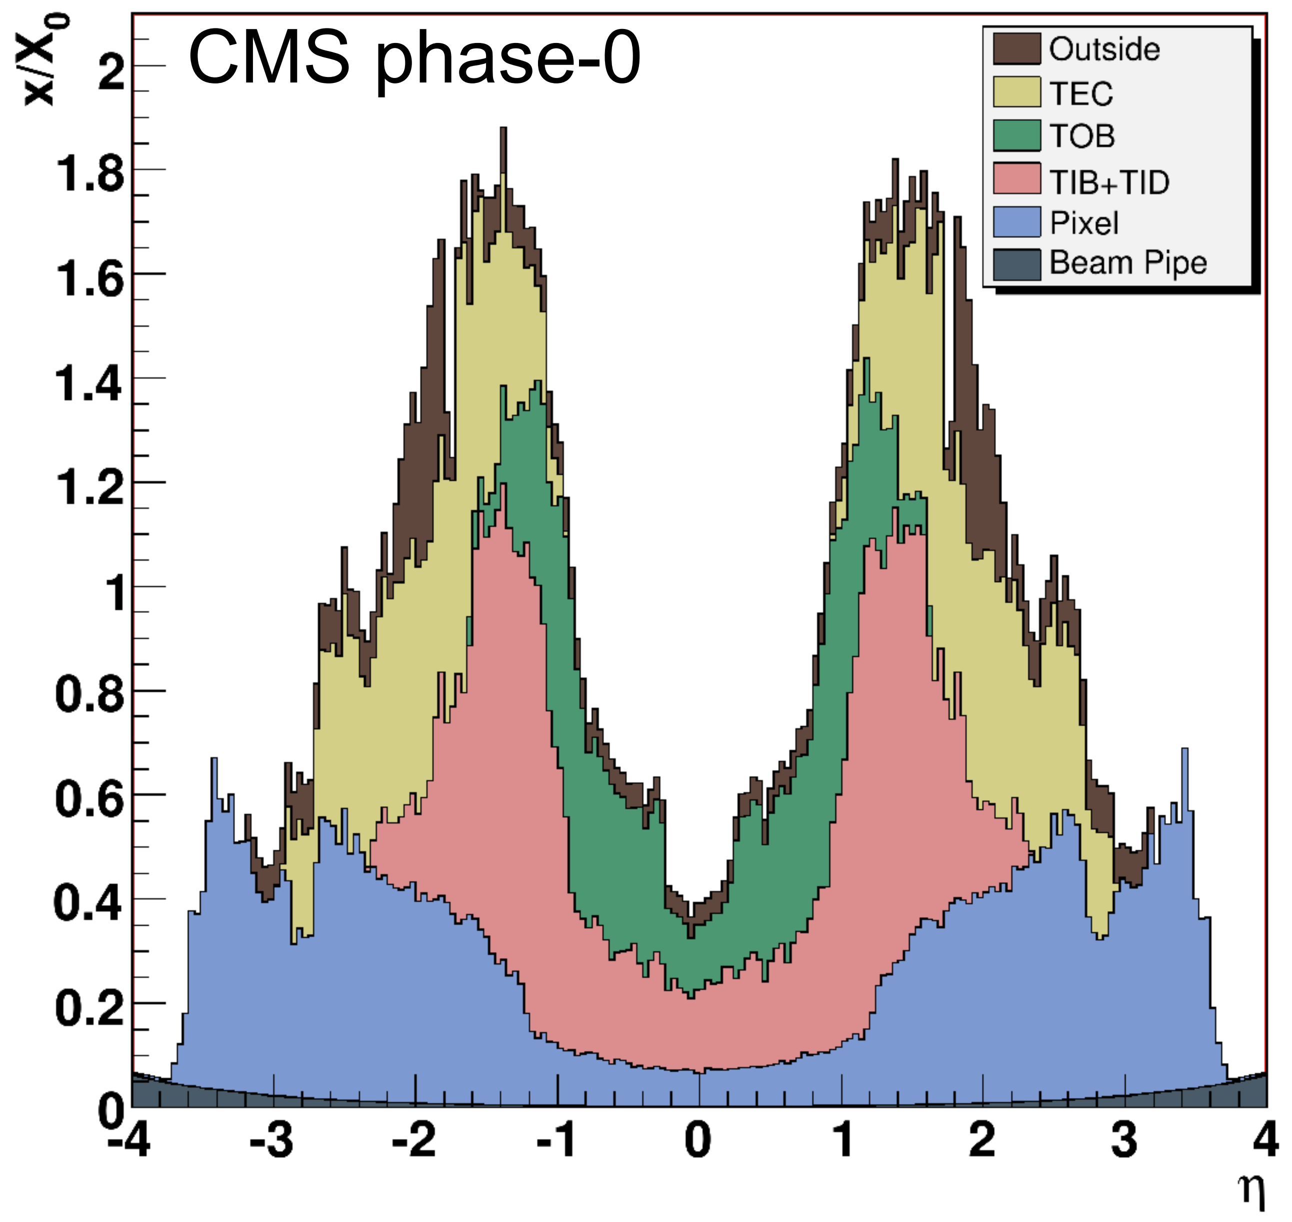
Electron Energy scale calibration in CDF and ATLAS







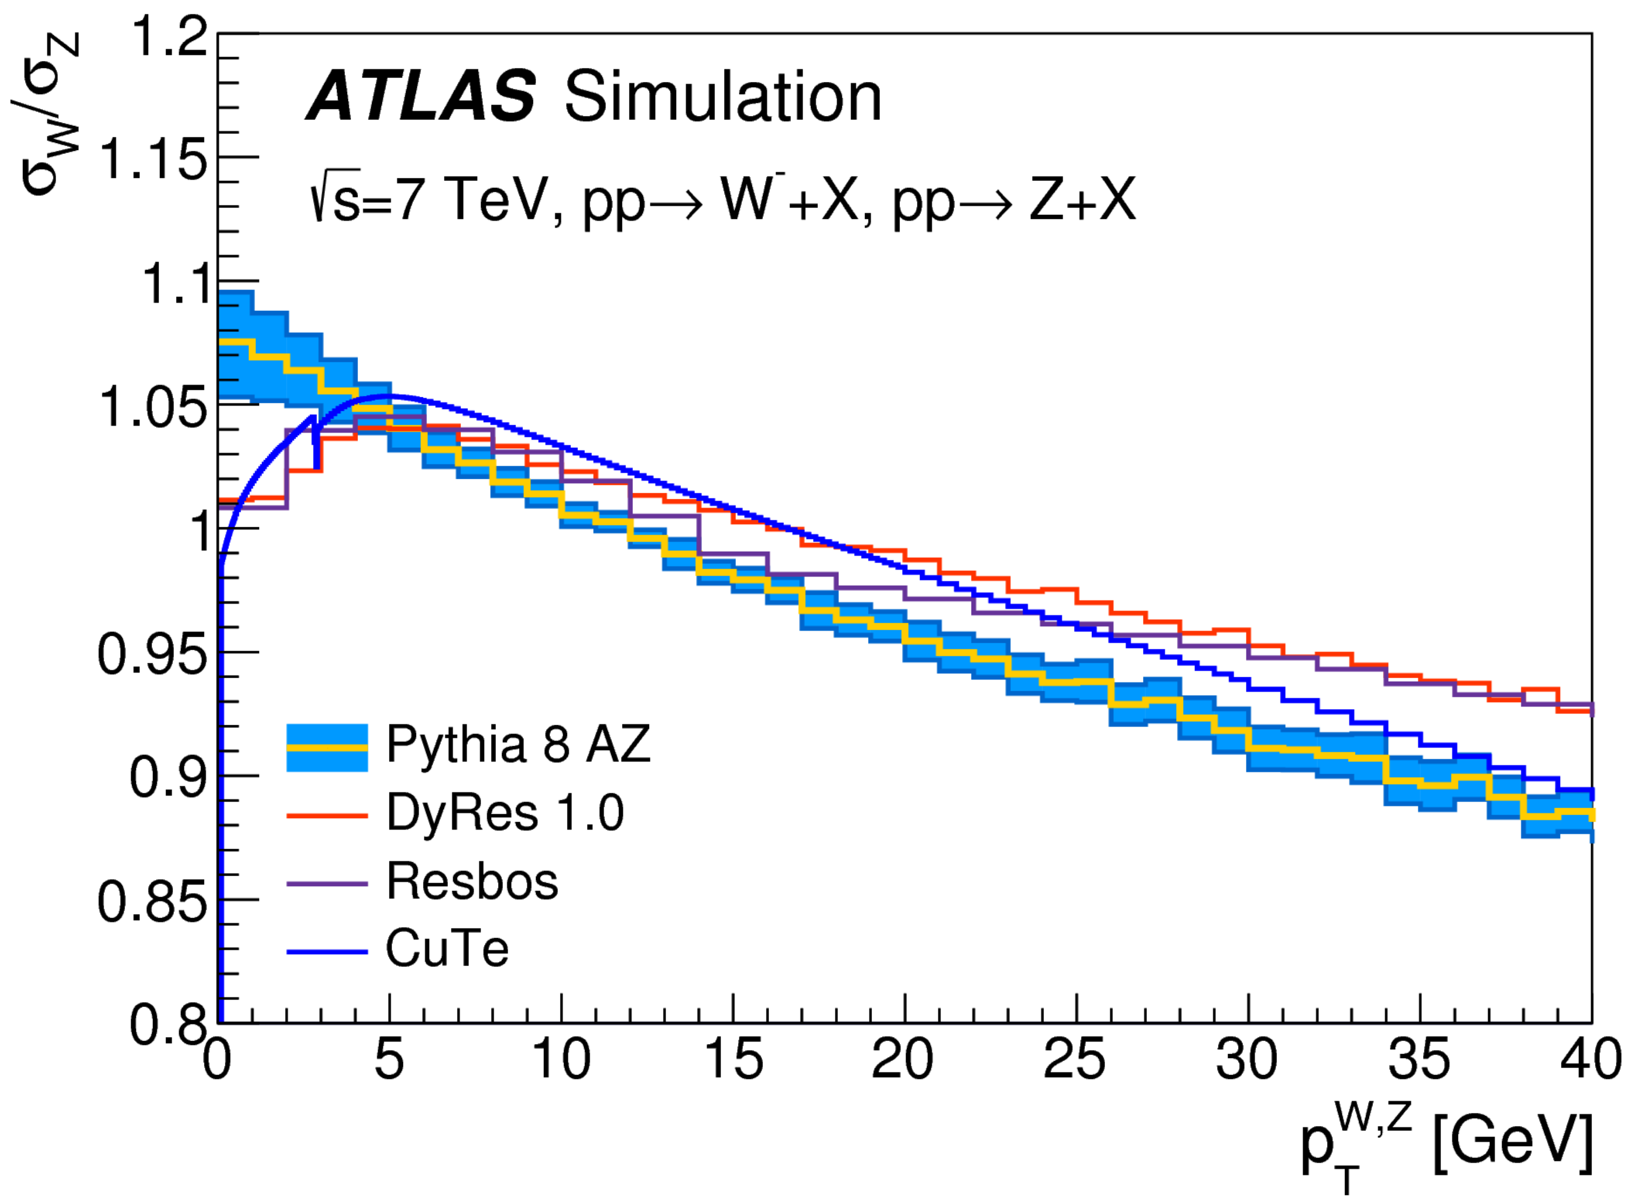
Tracker Material Budget

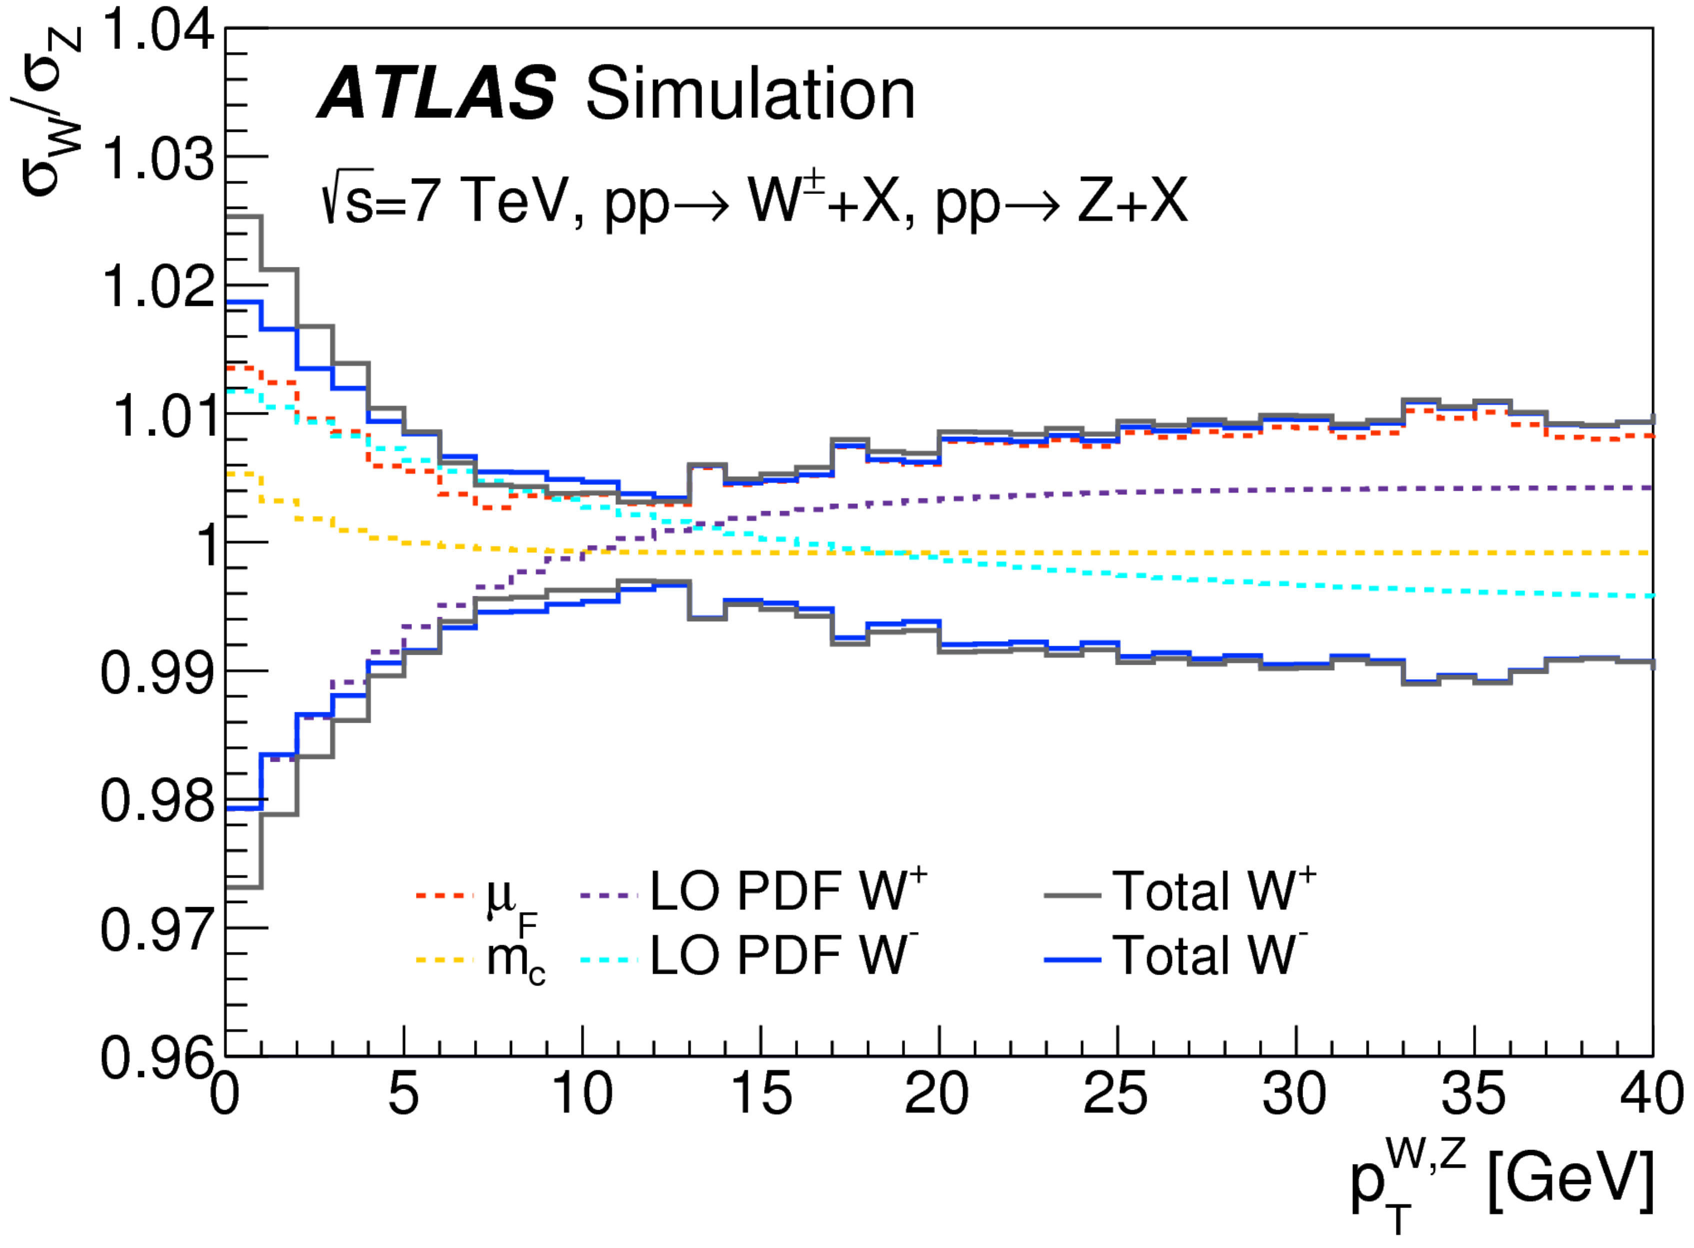


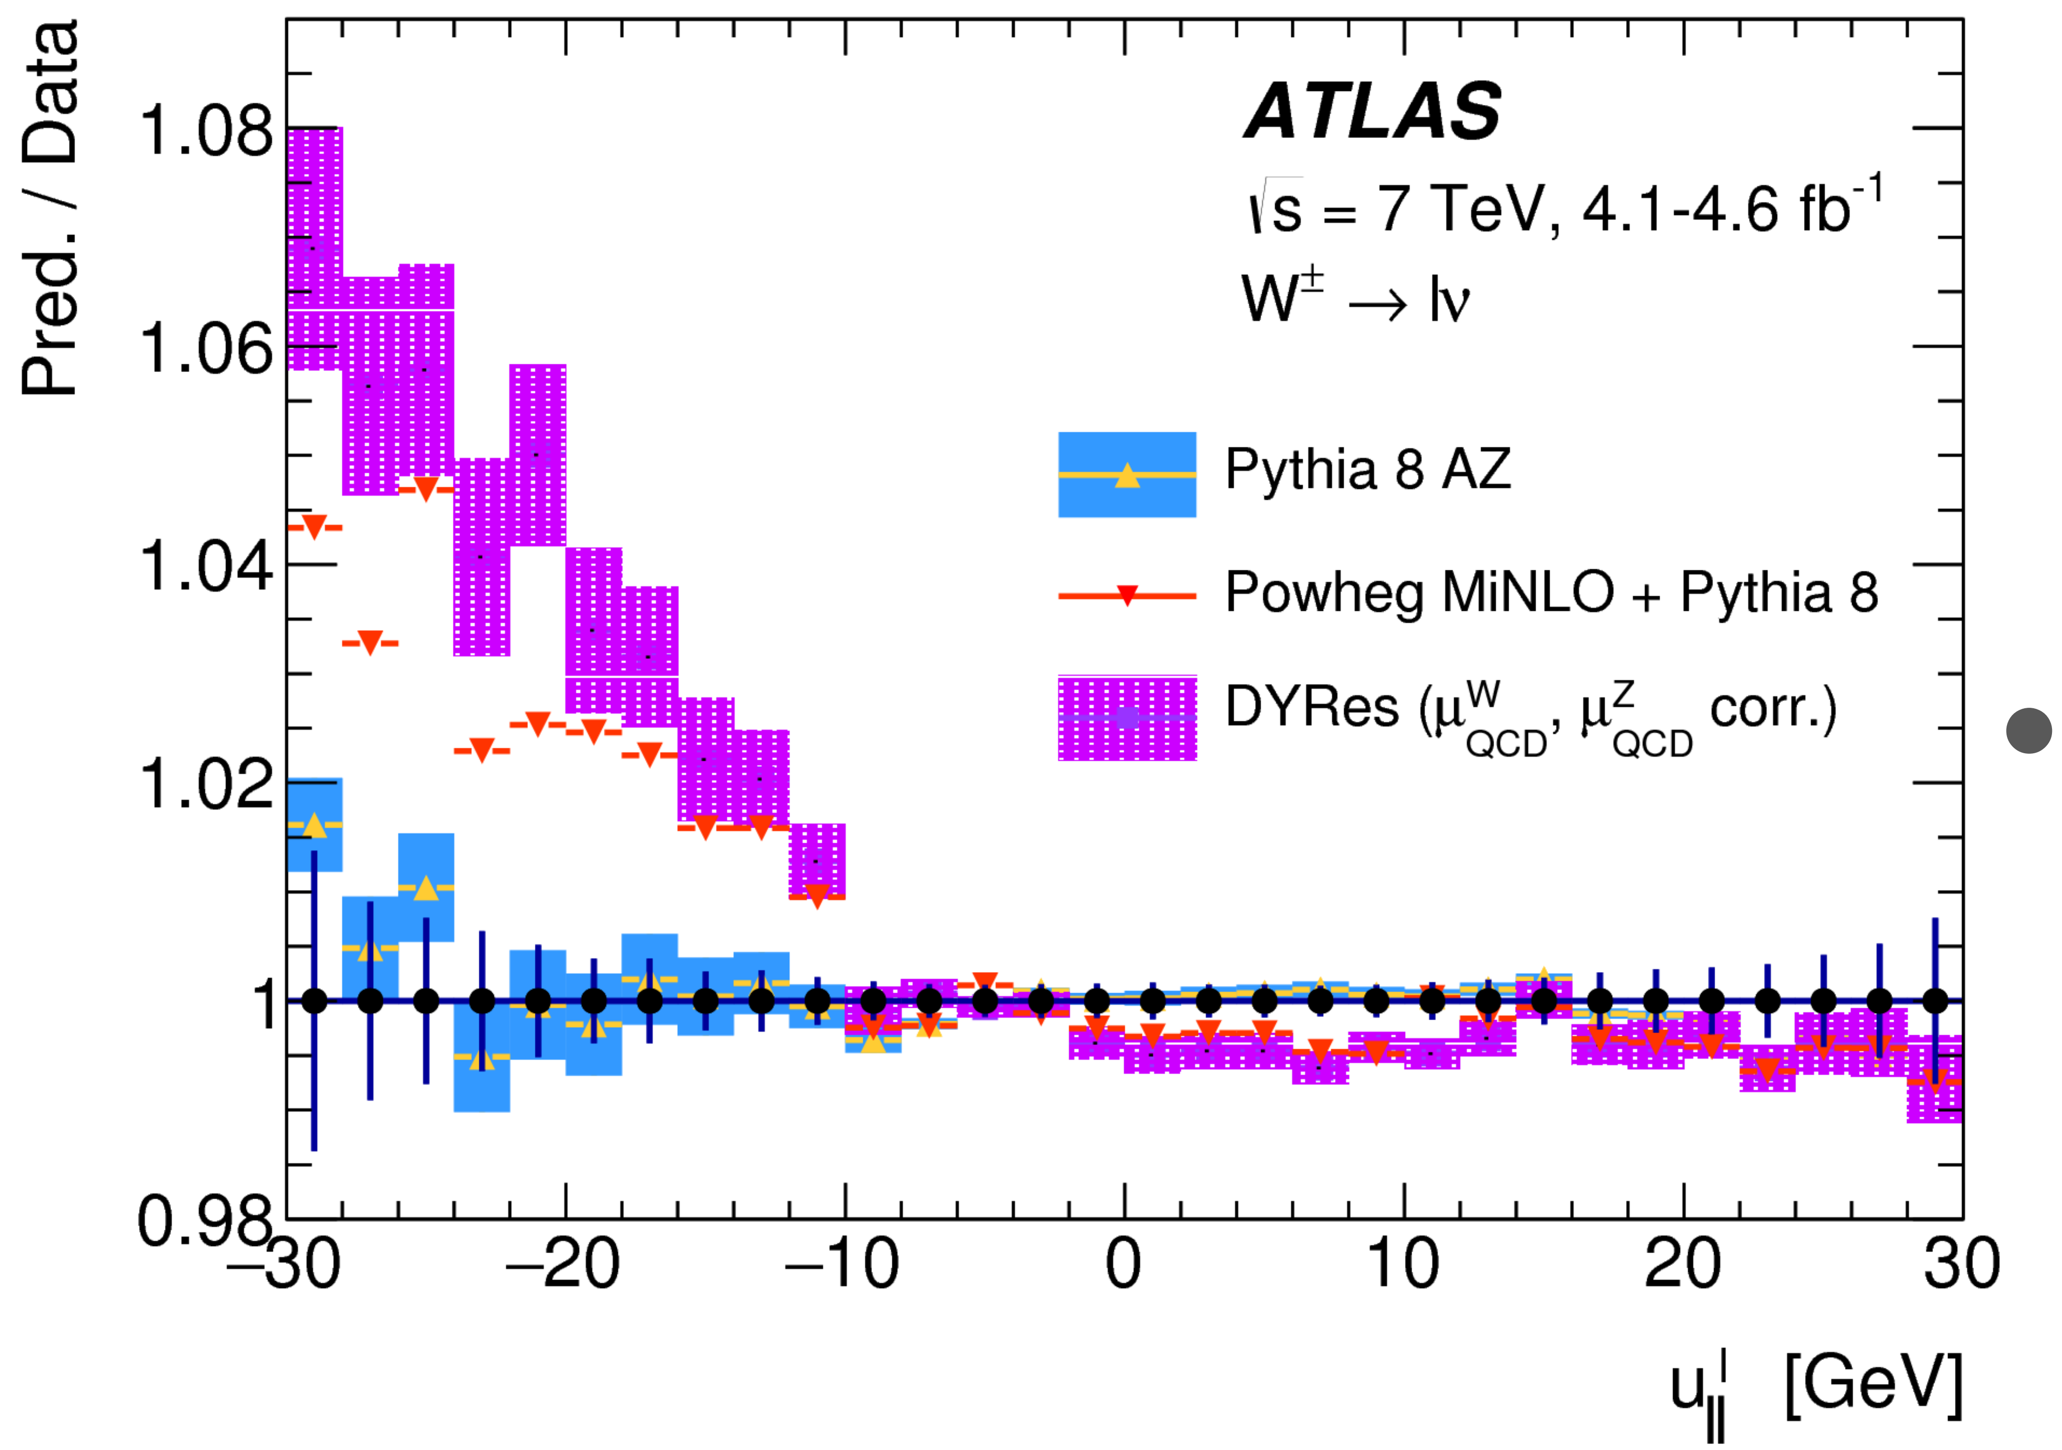
- CDF quotes systematic uncertainties on electron energy scale < 1e-4
- Achieved by transporting ultra high precision tracking calibration from muons to electron tracks and then using E/p
- CDF has < 0.2 radiation lengths of material in the tracking volume however…
- Quoted ATLAS electron energy scale uncertainties are approaching 1e-4, but rely maximally on Z->ee for calibration

ATLAS: Production Modeling

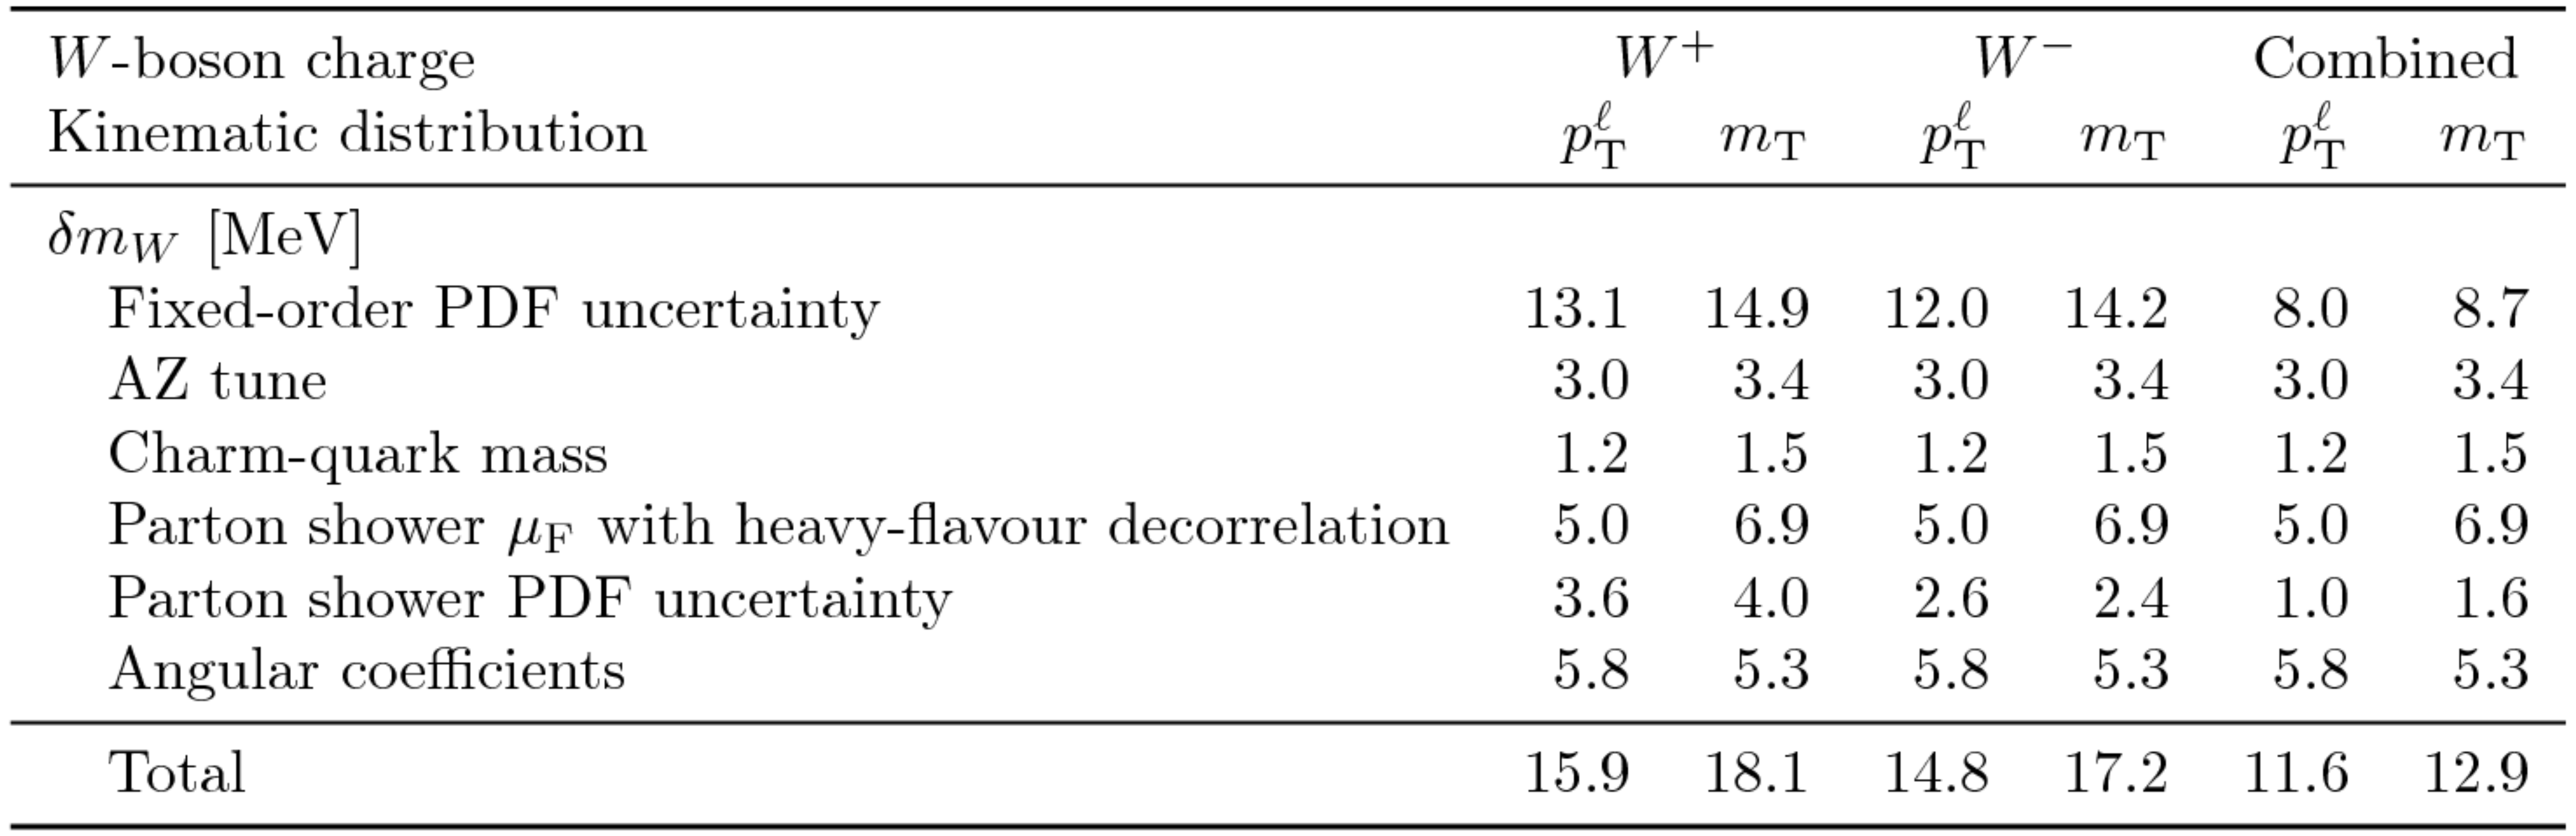
Eur. Phys. J. C 78 (2018) 110







- Measured hadronic recoil distribution has some sensitivity to W pT distribution, appears to disfavour more advanced calculations of W/Z pT ratio
- Measurement relies on Pythia model tuned to Z pT, with residual uncertainties for W->Z extrapolation



W-boson charge	W^+		W^-		Combined	
Kinematic distribution	p_T^ℓ	m_T	p_T^ℓ	m_T	p_T^ℓ	m_T
δm_W [MeV]

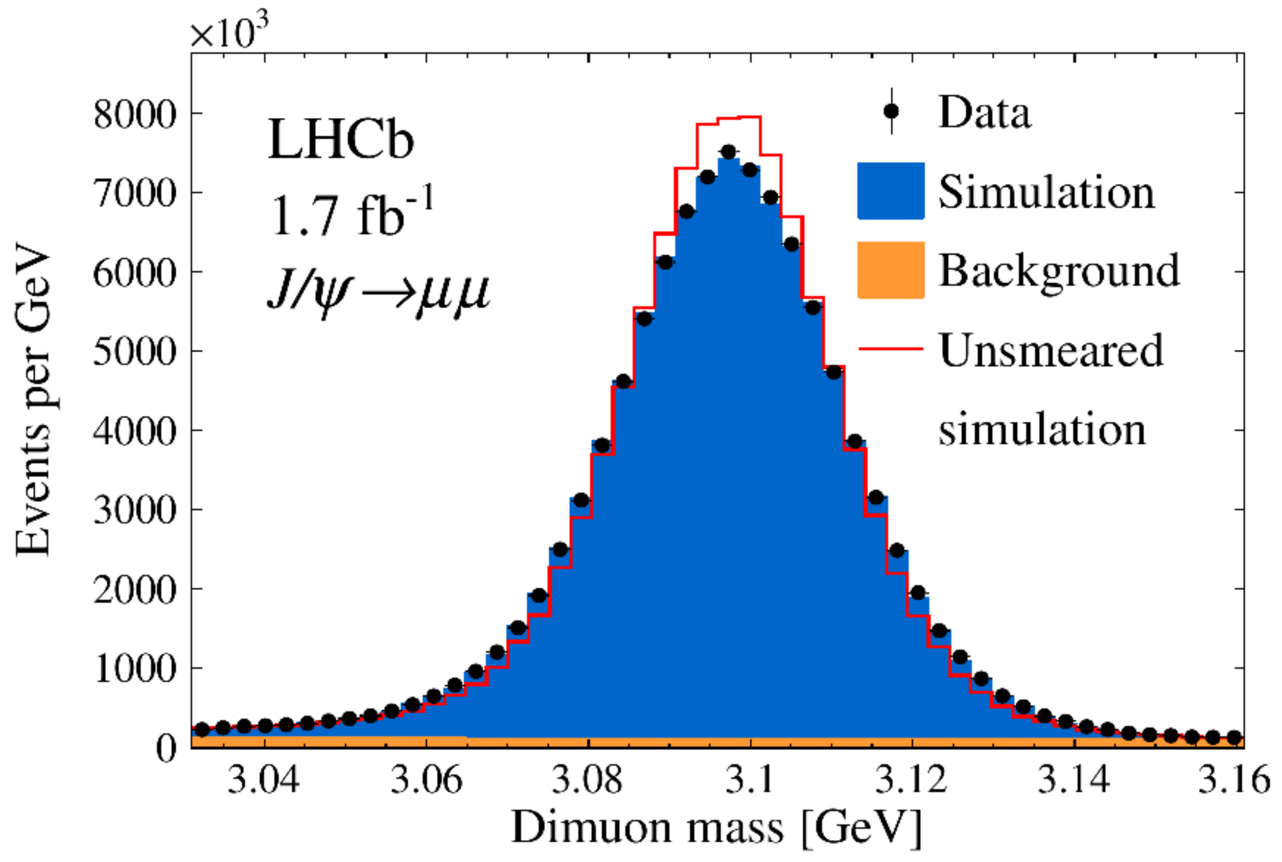
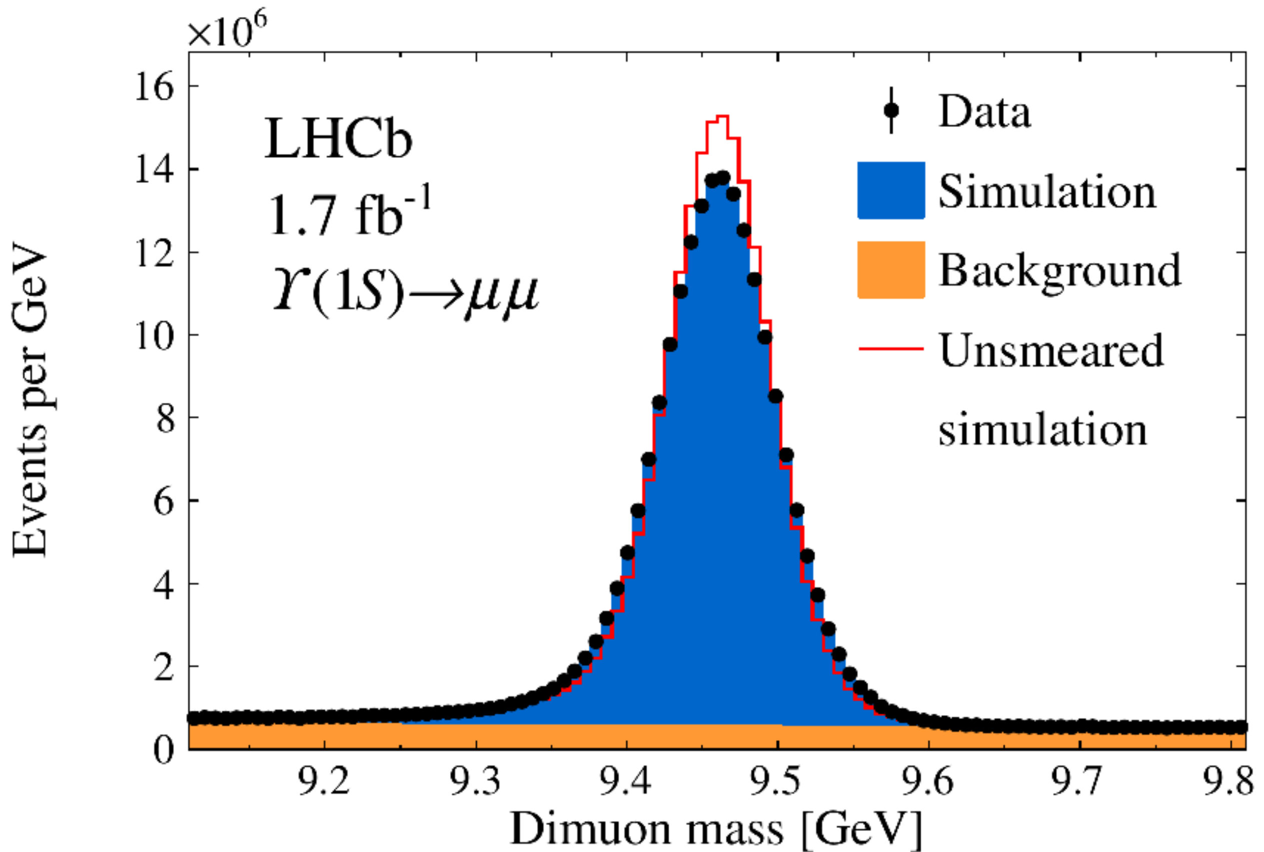
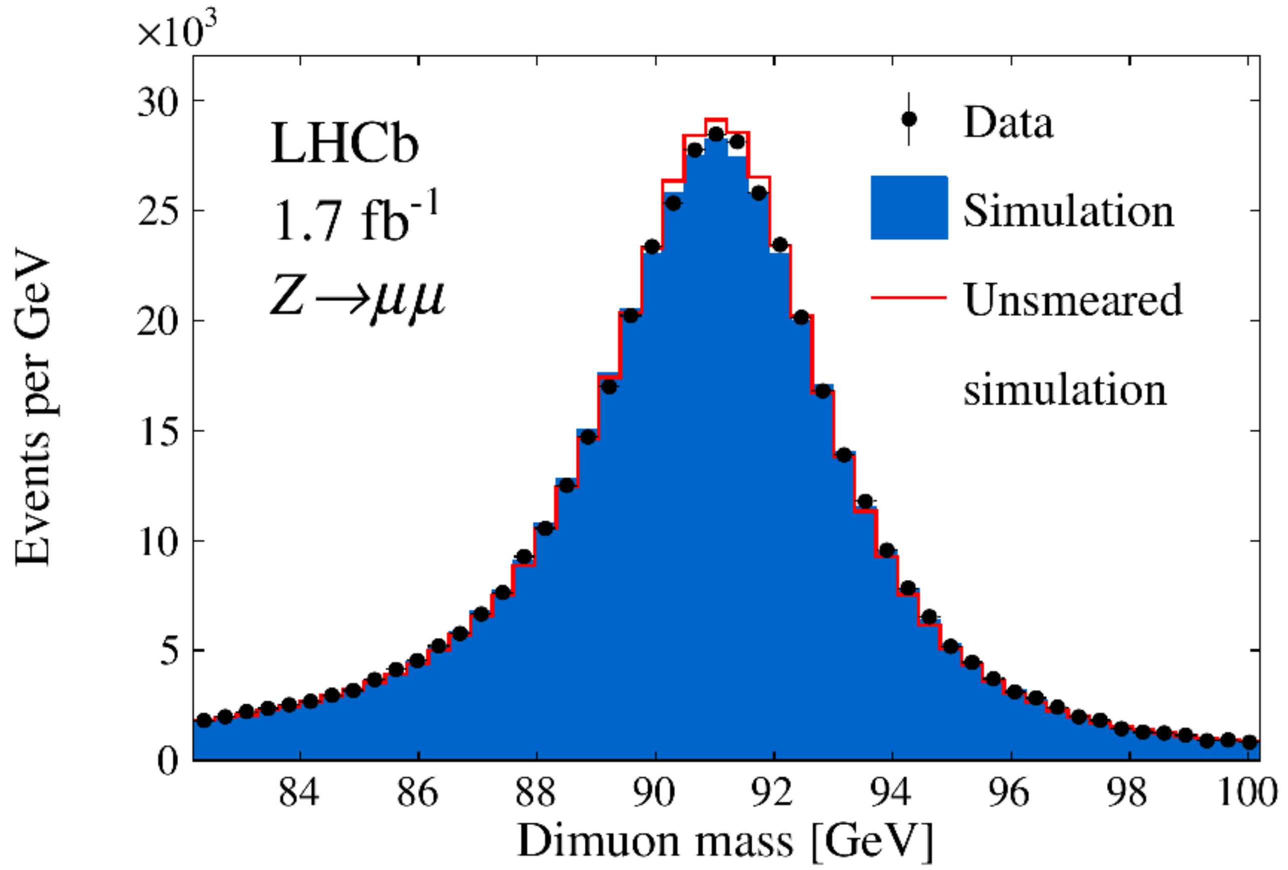
$$m_W = 80354 \pm 23_{\rm stat} \pm 10_{\rm exp} \pm 17_{\rm theory} \pm 9_{\rm PDF}\ \mathrm{MeV}.$$

- Detector design limits measurement to muon transverse momentum, but excellent calibration possible with quarkonia
- Unique forward phase space



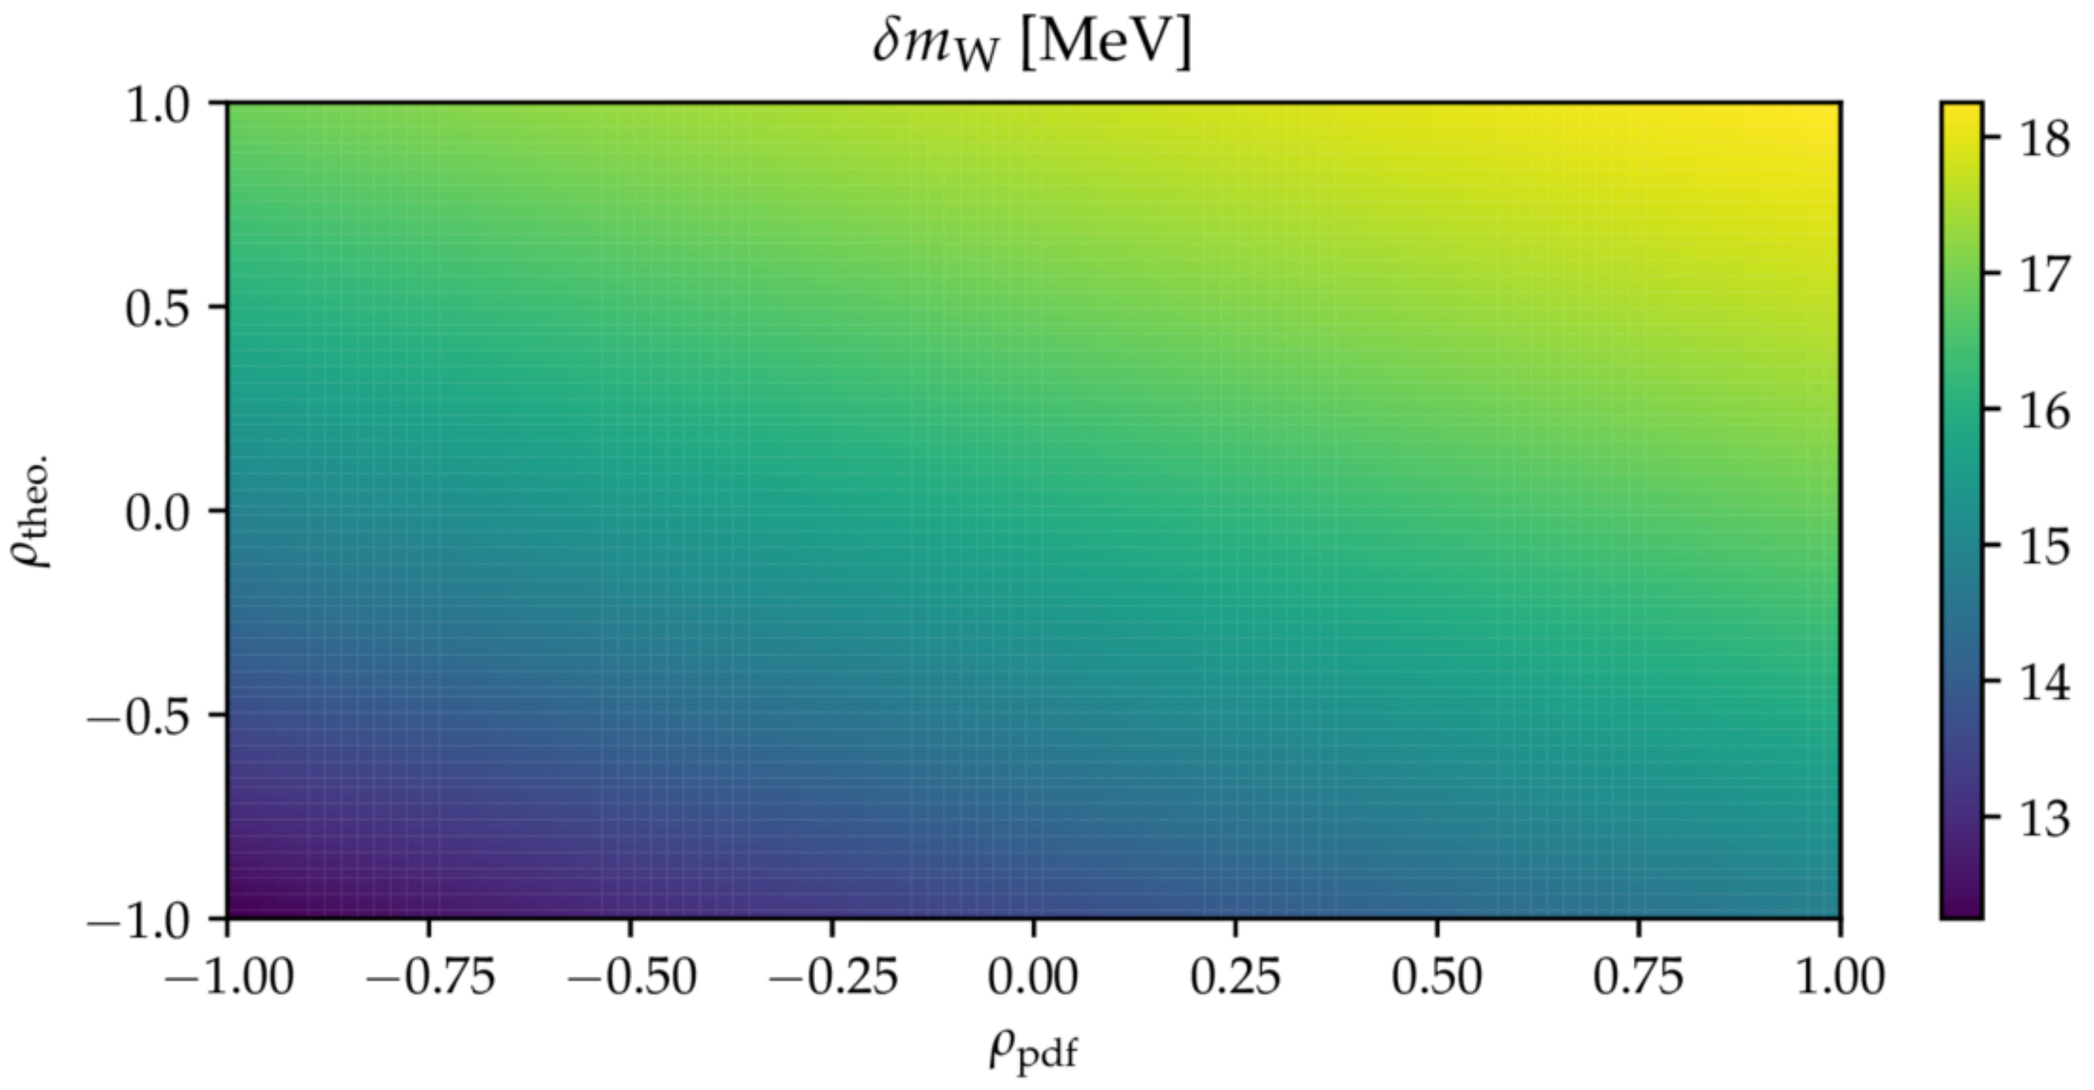


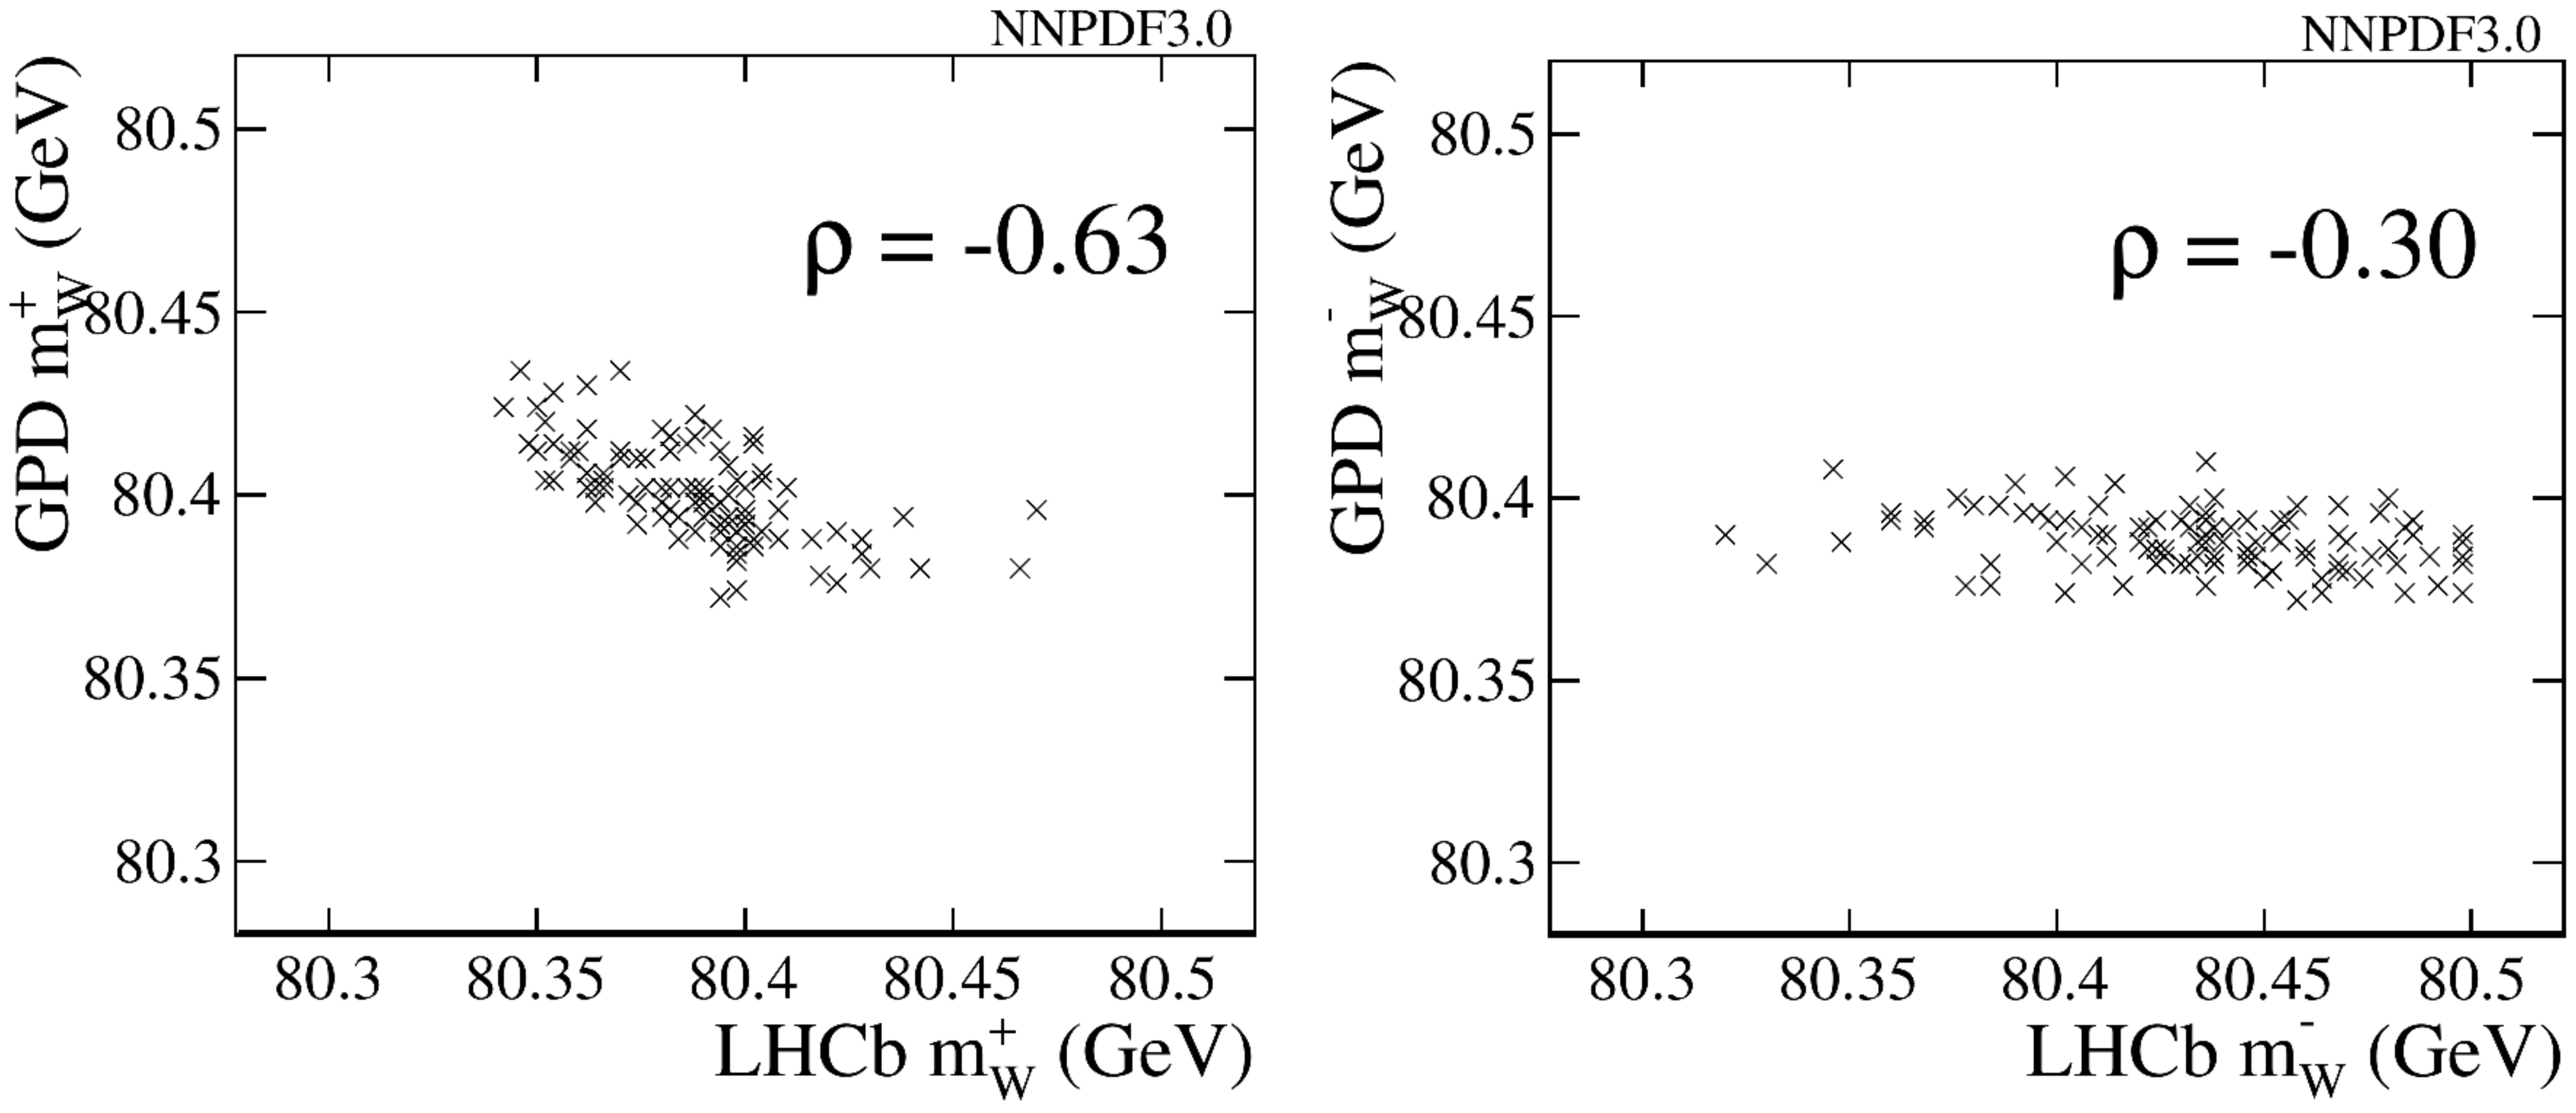


JHEP 01 (2022) 036

LHCb Combination prospects

- Forward phase space with respect to ATLAS and CMS leads to an anti-correlation of PDF uncertainties
- PDF uncertainties can be further reduced in combination





Eur. Phys. J. C **75**, 601 (2015)

D0

Phys. Rev. D 89, 012005 (2014)

- Measurement with 4.3 +1.0/fb in electron channel
- Electron energy scale, hadronic recoil, theory model calibrated/tuned with Z->ee

$$M_W = 80.375 \pm 0.023 \text{ GeV}.$$

Correlated χ^2	75	62	210	88	81	41	83
Total χ^2 / d.o.f.	200 / 126	196 / 126	444 / 126	270 / 126	210 / 126	162 / 126	236 / 126
p(χ^2, n)	0.003%	0.007%	$< 10^{-10}$	$< 10^{-10}$	0.0004%	1.5%	10^{-8}

Table 6: χ^2 per degree of freedom for the Tevatron Z-rapidity and W- and l-asymmetry measurements at $\sqrt{s} = 1.96$ TeV, and the LHC Z-rapidity and W lepton-rapidity measurements at $\sqrt{s} = 7$ TeV. The total χ^2 is the sum of those quoted for individual measurements along with a separate contribution for correlated uncertainties, where the latter is extracted using a nuisance parameter representation of the χ^2 [47]. The CT14 and CT18 PDF uncertainties correspond to 68% coverage, obtained by rescaling the eigenvectors by a factor of 1/1.645. The probability of obtaining a total χ^2 at least as high as that observed is labelled p(χ^2, n).
