## **CDF Mw measurement**

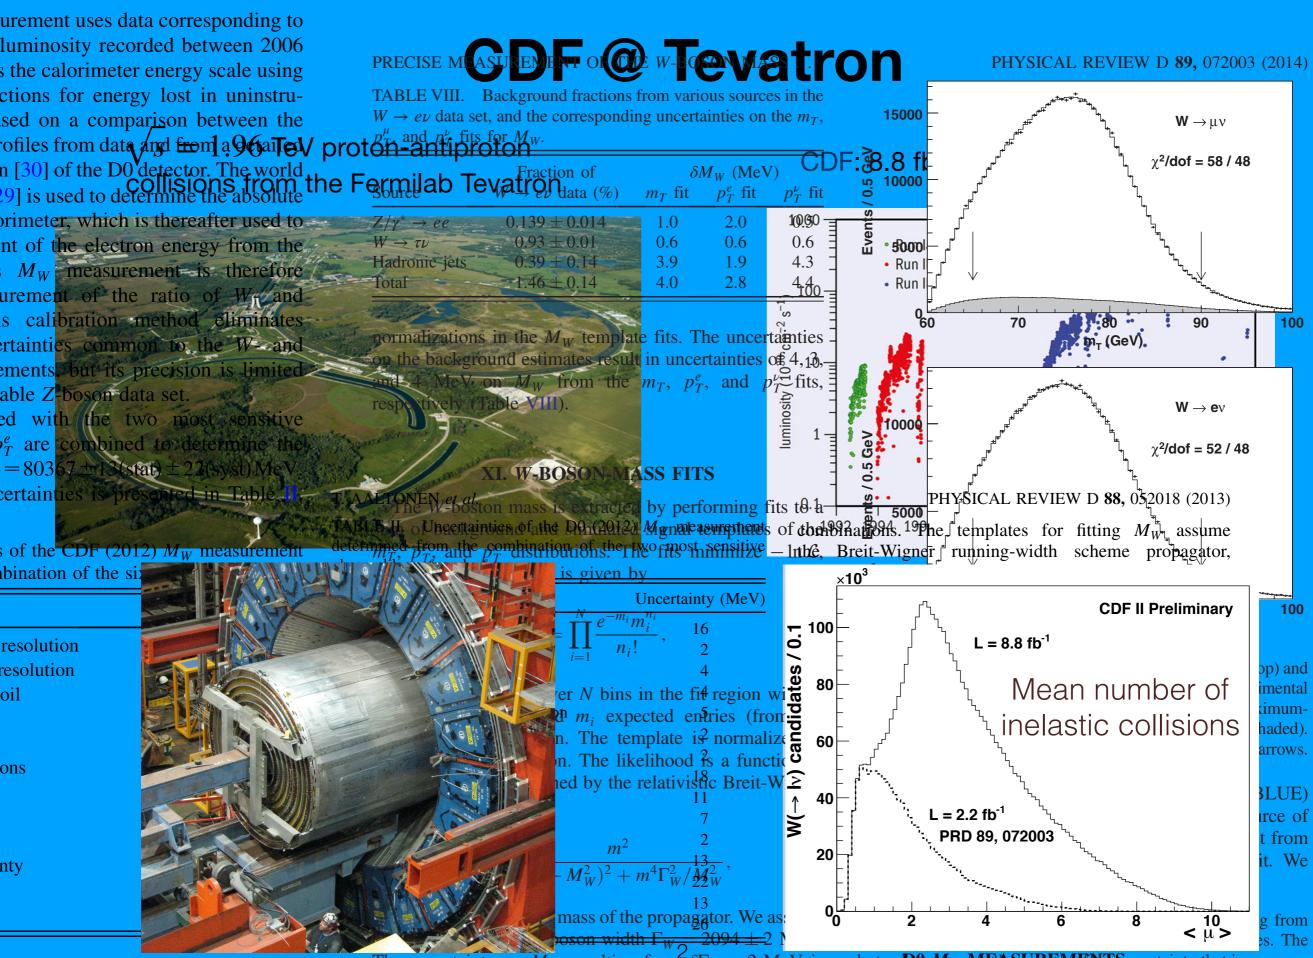

**Chris Hays, Oxford University** 

Mw Workshop Paris 30 June 2025

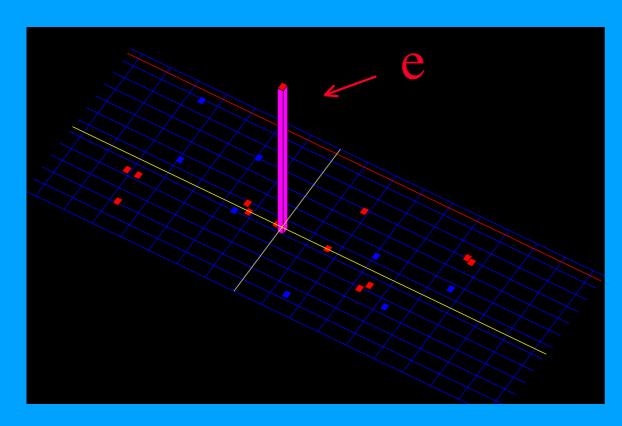

#### 0 measurement

The uncertainty on  $M_W$  resulting from  $\delta\Gamma_W = 2$  MeV is

last co**Don Map of FLAS FOREMENTS** incertainty that is common in the year and every results

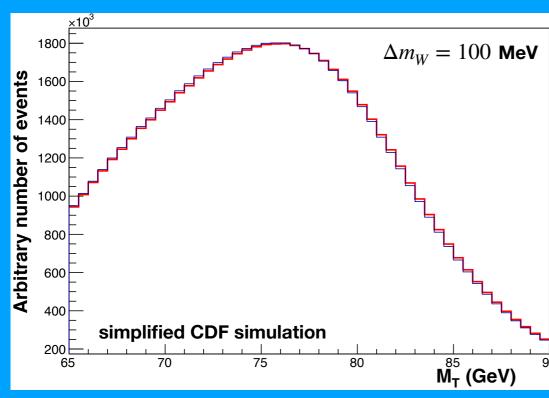

### **Measurement overview**

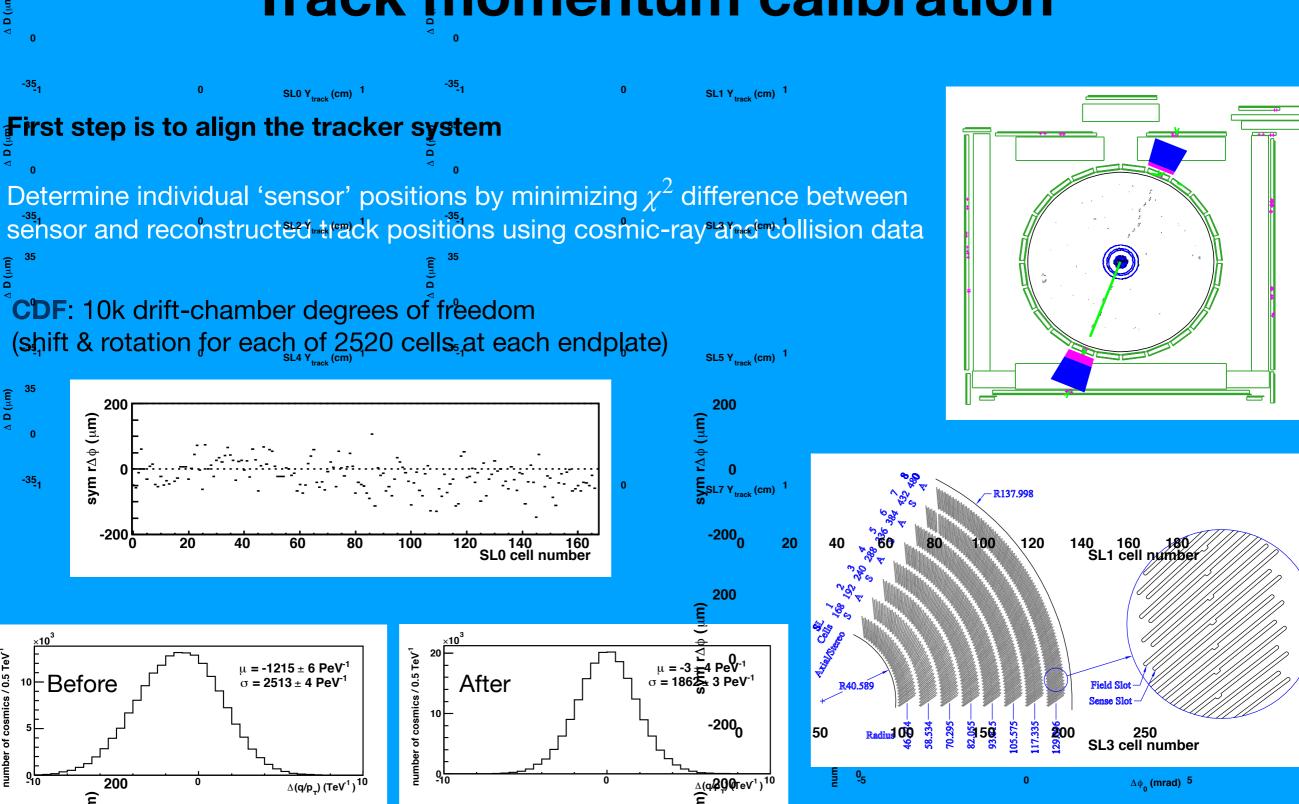

W bosons identified in their decays to  $e \nu$  and  $\mu \nu$ 

Mass measured by fitting template distributions of transverse momentum and mass

$$m_T = \sqrt{2p_T^l p_T \left(1 - \cos \Delta \phi\right)} \quad p_T^W$$
 
$$\vec{p}_T = -(\vec{p}_T^{\ l} + \vec{u}_T) \quad p_T^W$$
 
$$p_T^W$$
 
$$\log \frac{1.02}{4} \quad \Delta m_W = 100 \text{ MeV}$$
 
$$\log \frac{1.015}{4} \quad \log \frac{1.0$$

## Track momentum calibration

μ = -1440 ± 14 μrad σ = 5727 ± 10 μrad

Kotwal & CH, NIMA 762, 85 (2014)

 $\mu = 5 \pm 10 \mu rad$ 

 $\sigma = 4327 \pm 7 \, u \, rad$ 

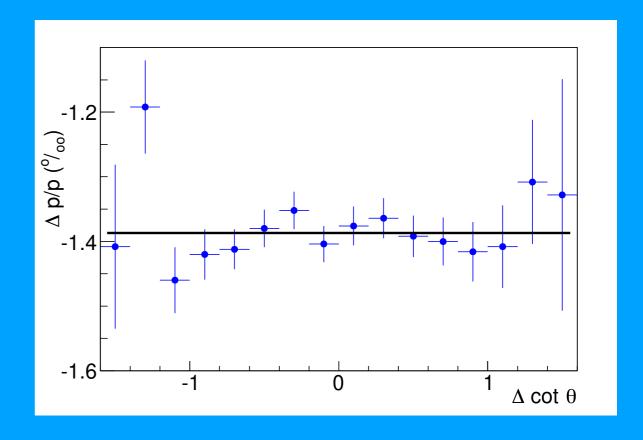

# Track momentum calibration p<sub>τ</sub>(μ) (GeV) Track momentum calibration p<sub>z</sub>(μ) (GeV)

Residual tracker misalignments corrected in track fits using difference in E/p between e- and e+

For the final track a small curvature correction as a function of  $\cot \theta$  is applied

Cubic polynomial for W/Z tracks Linear for mesons

#### **Ongoing studies:**

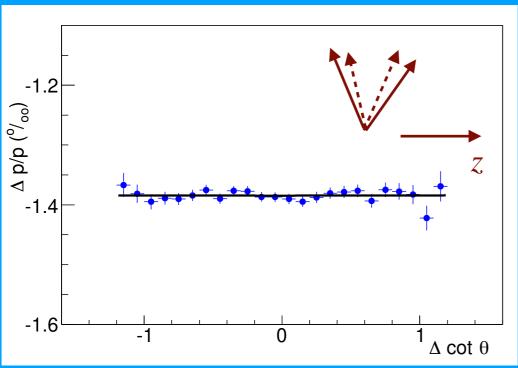

apply small corrections for time-dependence add a quadratic term to the correction for muons from meson decays separately obtain corrections for beam-constrained (BC) and non-beam-constrained (NBC) tracks

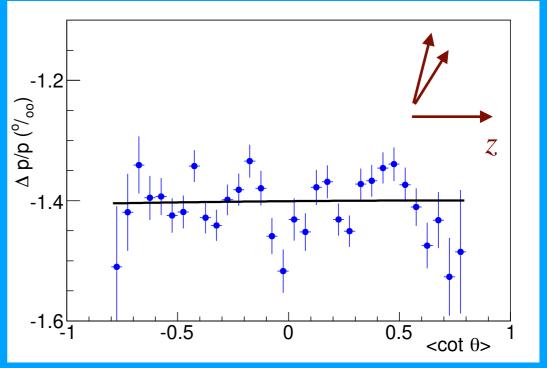

## **Track momentum calibration**

Additional corrections for tracker length, tracker material, and magnetic field non-uniformity

Material and field corrections determined using  $J/\psi$  decays

Tracker length determined separately for  $J/\psi$  and  $\Upsilon$  decays

 $(^{\circ\circ}/_{\circ}) d/d \nabla$  -1.4

-1.6

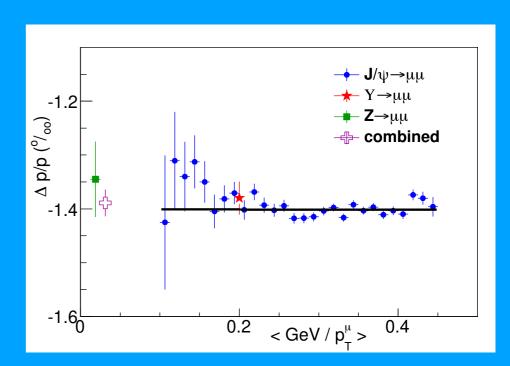

#### **Ongoing study:**

 $\theta > 1$ 

separate field and length corrections for BC and NBC tracks in  $\Upsilon$  decays

## Track momentum calibration

Third step is to calibrate the momentum scale using  $J/\psi$ ,  $\Upsilon$ , and Z decays to muons

Z boson mass in the muon decay channel is measured to be

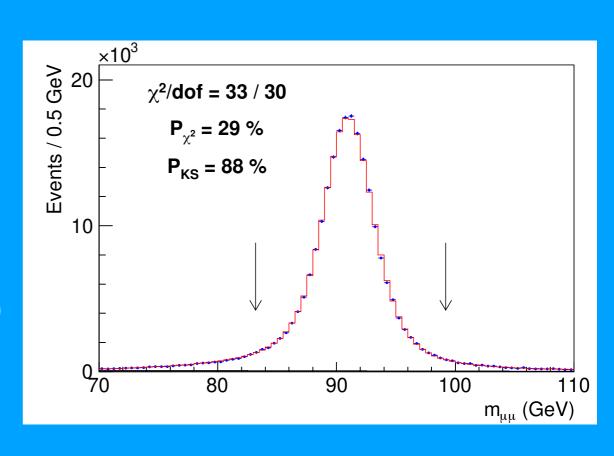

$$M_Z = 91\ 192.0 \pm 6.4_{stat} \pm 4.0_{sys} \text{ MeV}$$

#### **Ongoing studies:**

Split measurements by time period & total calorimeter energy (correlated with pileup)

Remove hits with large residuals (>300 microns) from track (default tracking uses hits with residual <600 microns, or  $\sim 4\sigma$ )

Separately fit for Mz using BC and NBC tracks

## **Electron momentum calibration**

#### First step is to correct the response variations in data

Use ratio of calorimeter energy to track momentum (E/p) to remove response variations with time and position within tower and in pseudorapidity

25 GeV

50 GeV

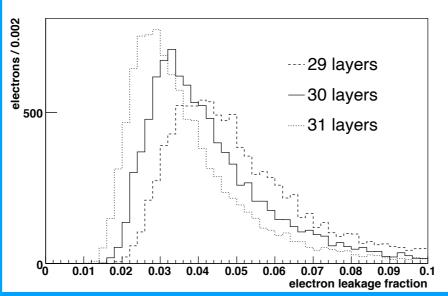

Second step is to simulate the energy loss

100 GeV

Tune the amount of upstream material using E/p from  $W \rightarrow e\nu$  events Correct the downstream energy leakage using E/p

Kotwal & CH, NIMA 729, 25 (2013)

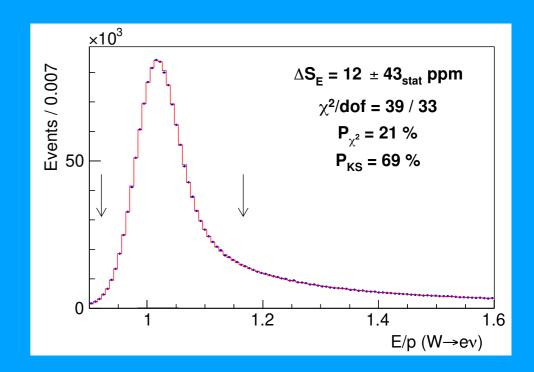

## **Electron momentum calibration**

#### Third step is to calibrate the response

**J**/ψ→μ Υ→μμ **Z**→μμ

Transfer track momentum calibration to calorimeter using (E/p) distribution, combine with calibration from  $Z \to ee$  decays

 $M_{Z_0} \stackrel{\text{def}}{=} 194.3 \pm 13.8_{stat} \pm 7.6_{sys} \text{ MeV}$   $\chi^2/\text{dof} = 33/30$   $P_{\chi^2} = 29 \%$   $P_{\text{KS}} = 88 \%$ Consistent with measurement in muon channel

Lower precision due to calorimeter dead regions

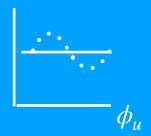

## Recoil momentum calibration

#### First step is data uniformity corrections

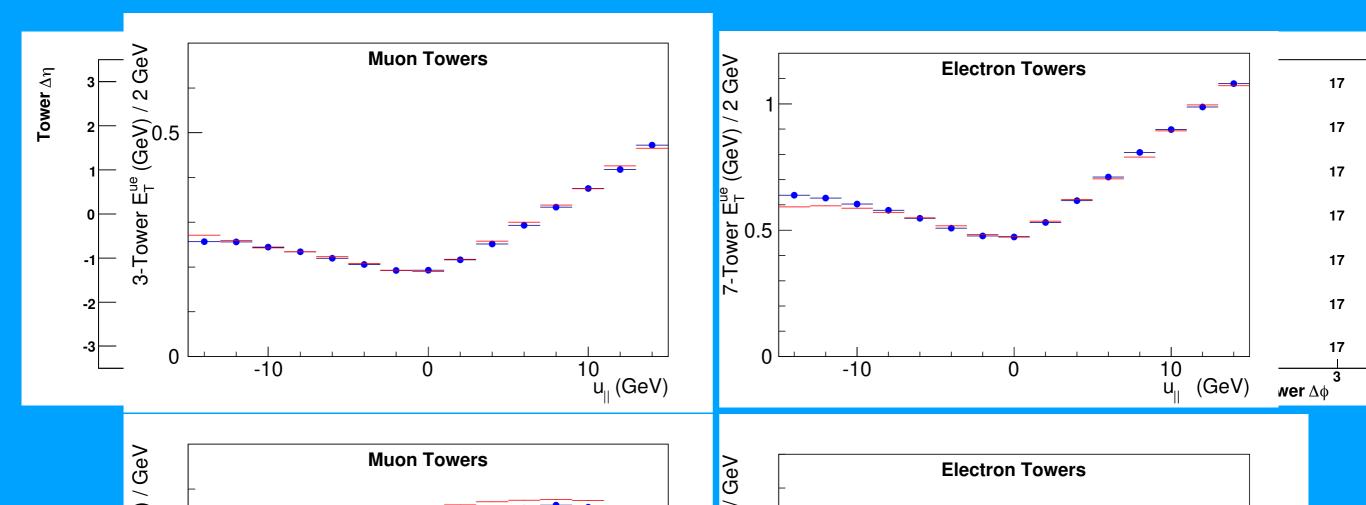

Align calorimeter relative to the beam axis to remove any modulation in the recoil direction

#### Second step is the reconstruction of the recoil

Remove custom tower windows traversed by electrons or muons

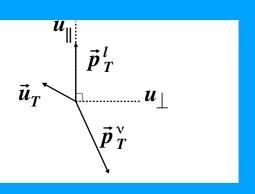

Remove corresponding recoil energy in simulation using a distribution from towers rotated by 90° Validate the procedure by studying towers rotated by 180°

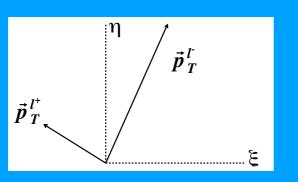

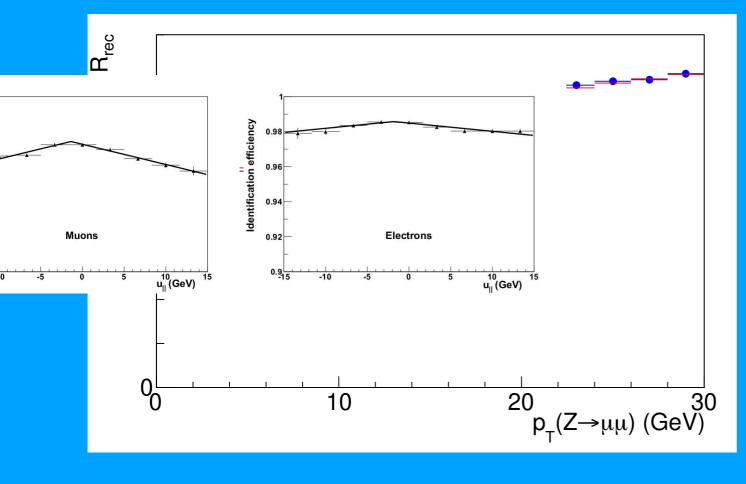

## **Recoil momentum calibration**

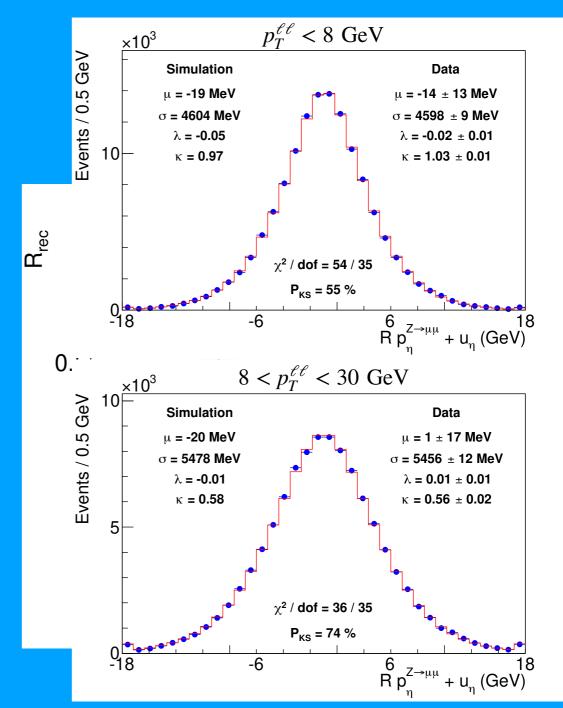

#### Third step is the calibration of the recoil response

Scale generated recoil to balance p<sub>T</sub><sup>Z</sup> and check observed response R<sub>rec</sub>

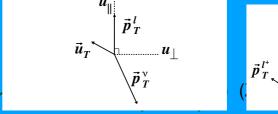

Events / 0.5 GeV

## Recoil momentum calibration 33 %

Fourth step is the calibration of the recoil resolution

Includes jet-like energy and angular resolution, additional dijet fraction

 $\sigma$  = 873 ± 2 mrad

 $\lambda = 0.58 \pm 0.01$ 

 $\kappa = -0.79 \pm 0.01$ 

 $\sigma$  = 875 mrad

 $\lambda = 0.58$ 

 $\kappa = -0.8$ 

 $\times 10^3$ 

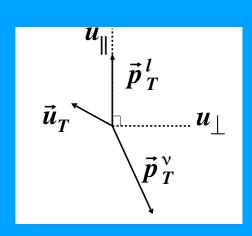

## **Recoil momentum validation**

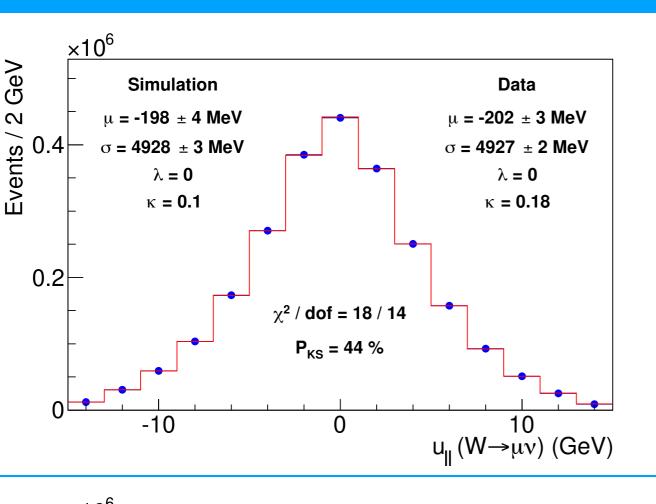

#### W boson recoil distributions validate the model

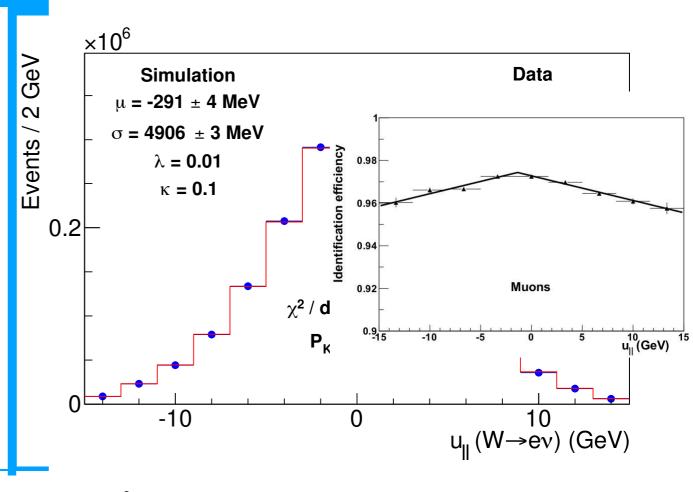

Most important is the recoil projected along the charged-lepton's momentum ( $u_{||}$ )

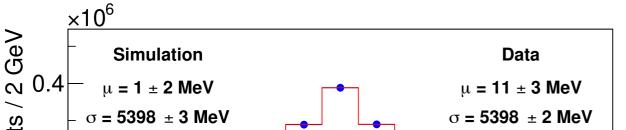

$$m_T \approx 2p_T \sqrt{1 + u_{||}/p_T} \approx 2p_T + u_{||}$$

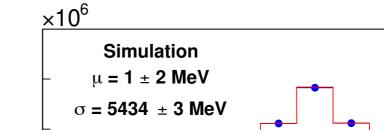

s / 2 GeV

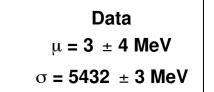

## W boson production

Transverse mass insensitive to  $p_T^W$  to first order O(1 MeV) change in  $m_W$  for each % change in  $p_T^W$  from 0-30 GeV

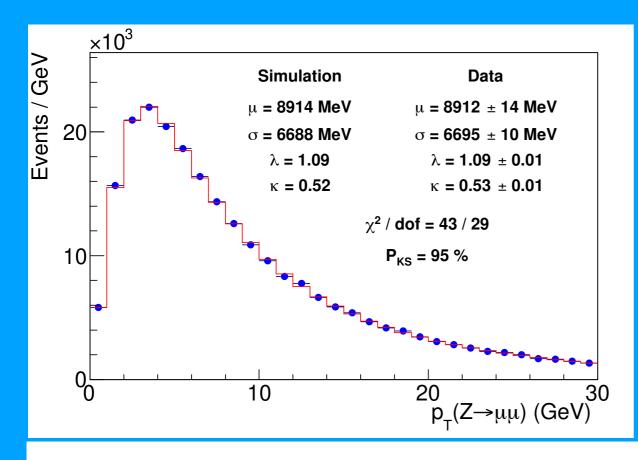

Lepton p<sub>T</sub> distributions more sensitive to p<sub>T</sub><sup>W</sup>

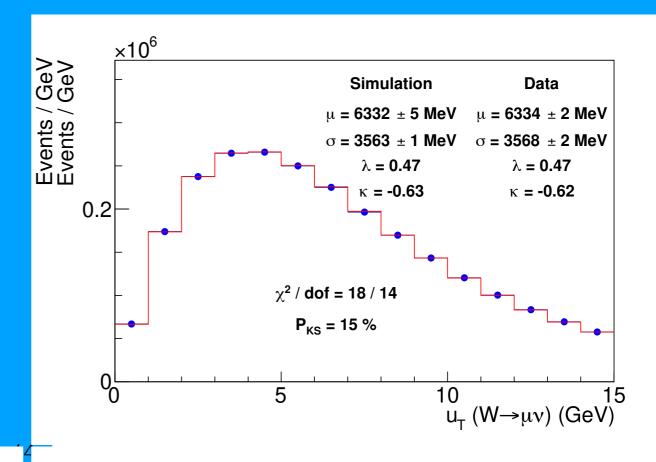

Generate events with Resbos: non-perturbative parameters & approximate NNLL resummation

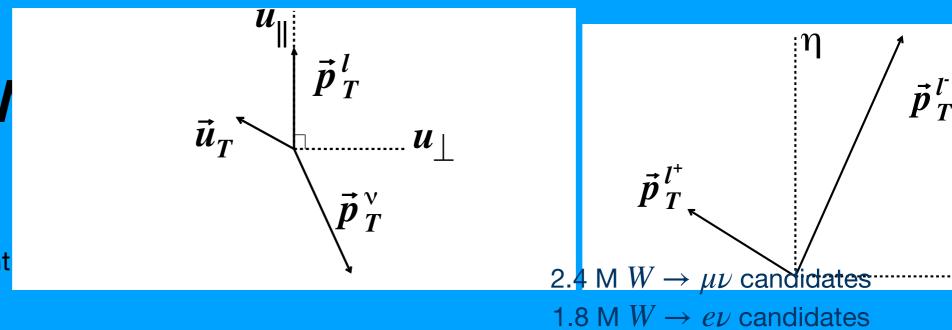

Z boson  $p_T$  constrains non-perturbative parameter(s)

Determine  $p_T^Z \to p_T^W$  uncertainty using DYQT perturbative & resummation scale variations

Use observed W recoil spectrum to constrain  $p_T^W$  uncertainty (reduces uncertainty by factor of ~2)

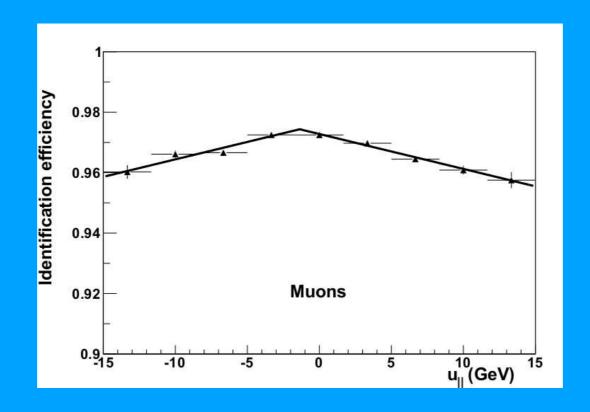

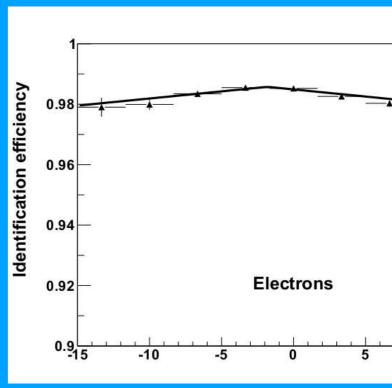

W boson event selection require kinematics consistent

#### **Lepton identification**

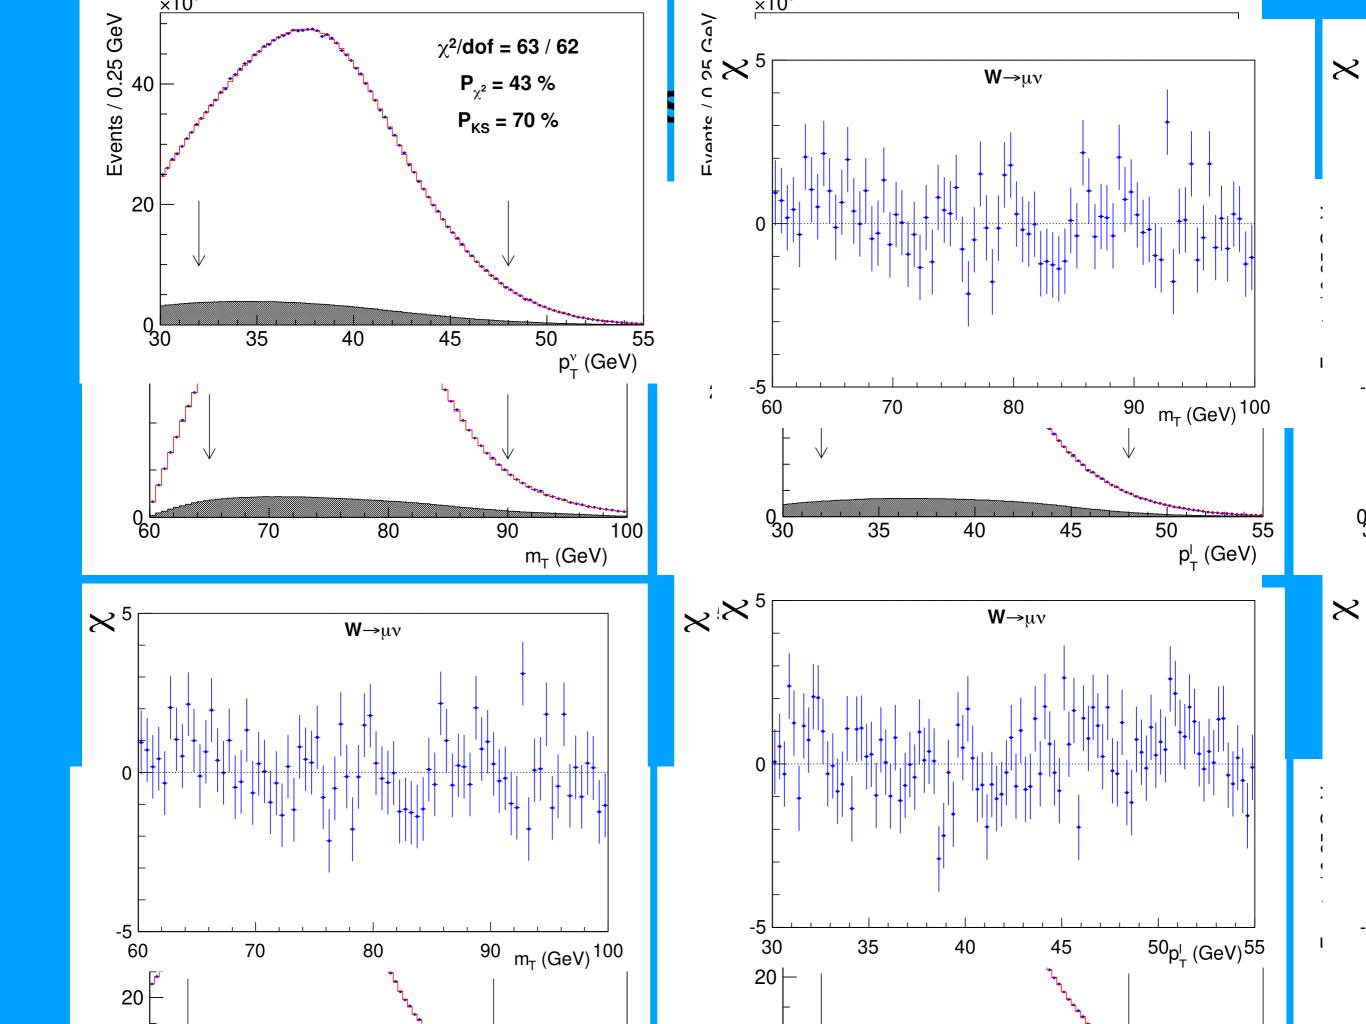

No lepton isolation requirement in trigger or offline selection High efficiency with little recoil dependence

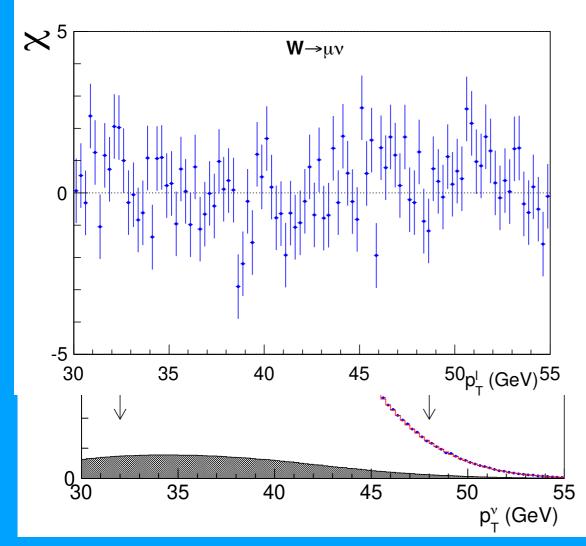

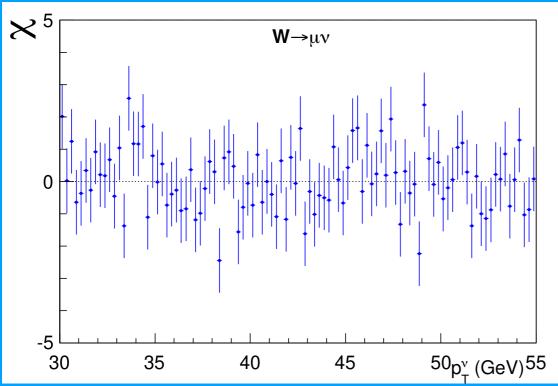

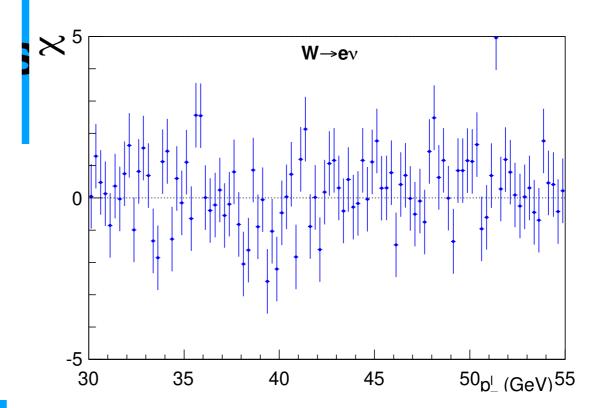

#### **Backgrounds**

Most challenging background comes from hadrons misreconstructed as leptons (0.2-0.3%)  $Z \to \mu\mu$  background is large (7.4%) and is modelled using several data-based corrections

	Distribution	W-boson mass (MeV)	$\chi^2/\mathrm{dof}$

## Summary

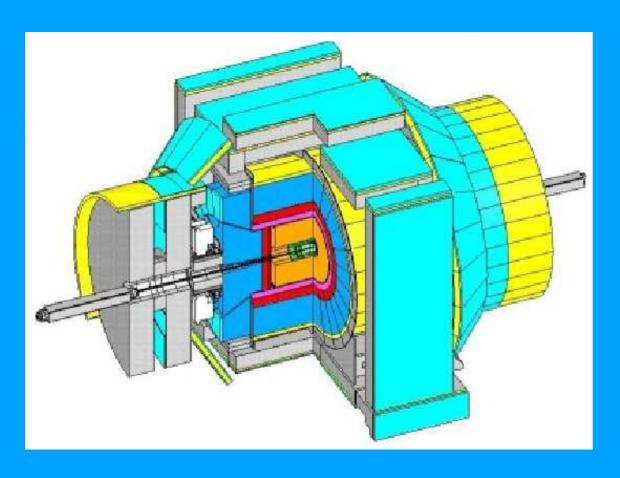

The W boson mass is a sensitive quantity to high-scale physics

Measurement with <10 MeV precision (~0.01%) achieved using the complete CDF data set

Result deviates significantly from other measurements

Further studies and cross-checks ongoing

## Backup

## **Future possibilities**

#### **Recoil tuning**

Fine-tune calorimeter response corrections in data Calibrate a shower Monte Carlo

#### **Recoil validation**

Compare W & Z response in events with a single lepton (remove any additional lepton) Compare W & Z energy flows

#### **Event generation**

Generate events using a higher-order calculation (e.g. Resbos2) Validate  $p_T^W$  using high/low  $p_T^I$  asymmetry Validate PDF using low  $p_T^I$  region and rapidity-dependent mass fits

#### **Event selection**

Vary lepton id (add isolation)

#### **Analysis updates**

Identify the effect of each analysis change in the muon channel

#### **Luminosity & time dependence**

Fit mass in subsets in time or luminosity

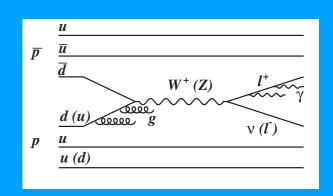

## W boson production and decay

#### Parton distributions impact the measurement through lepton acceptance

Restriction in  $\eta$  reduces the fraction of low-p<sub>T</sub> leptons

#### Small correction applied to update to NNPDF3.1 NNLO PDF

The set with the most W charge asymmetry measurements at the time

#### Uncertainty determined using a principal component analysis on the replica set

Measurement sensitive to ~15 eigenvectors

Leading 25 eigenvectors used to estimate uncertainty (3.9 MeV)

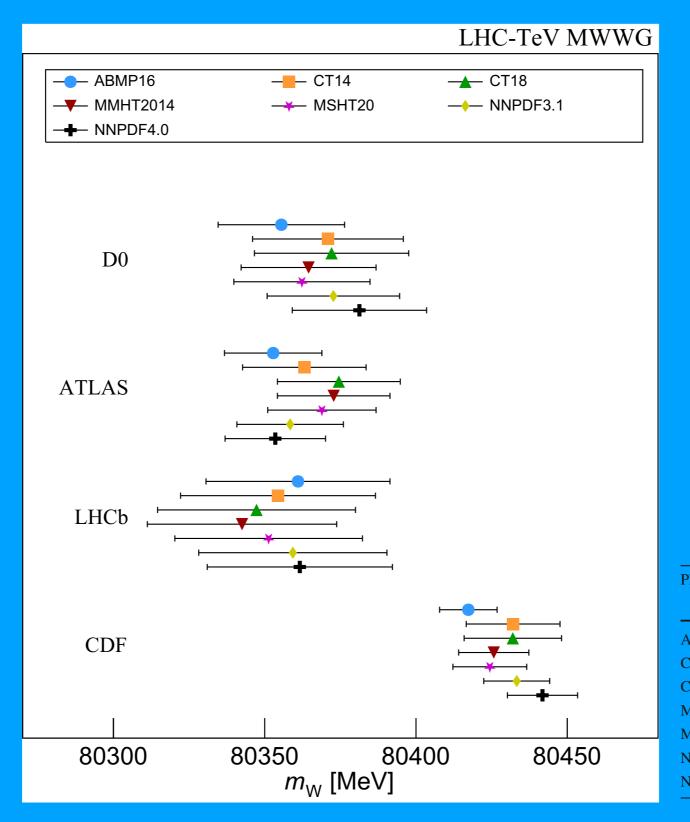

Three general NNLO PDF sets (NNPDF3.1, CT18, and MMHT14) have a range of  $\pm 2.1$  MeV from mean

### **Detector simulation**

#### **Developed custom simulation for analysis**

Models ionization energy loss, multiple scattering, bremsstrahlung, photon conversion, Compton scattering

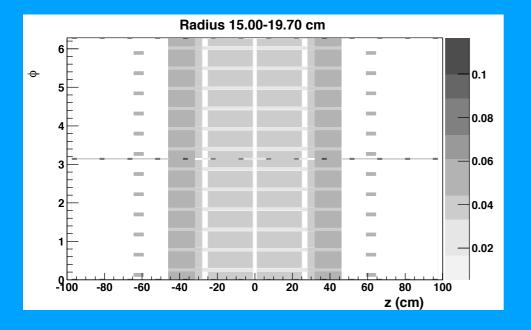

Acceptance map for muon detectors

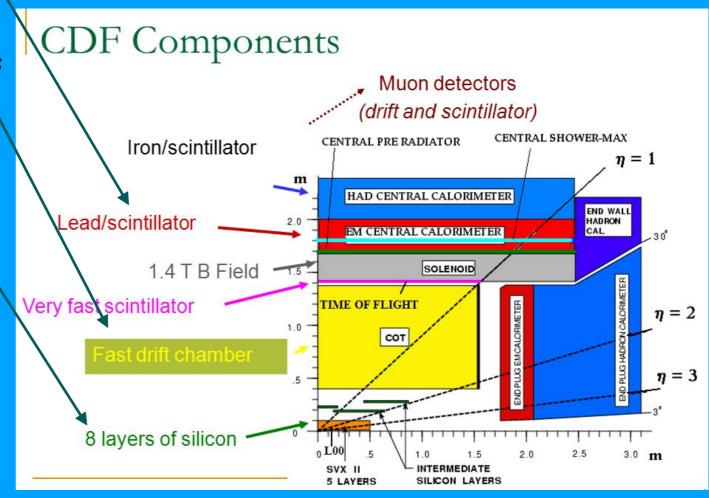

Parameterized GEANT4 model of electromagnetic calorimeter showers Includes shower losses due to finite calorimeter thickness

Kotwal & CH, NIMA 729, 25 (2013)

Hit-level model of central outer tracker Layer-by-layer resolution functions and efficiencies

Material map of inner silicon detector Includes radiation lengths and Bethe-Bloch terms

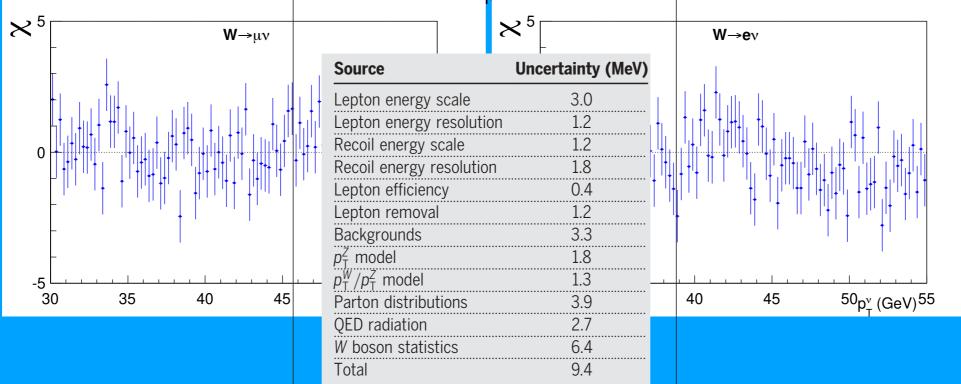

## Measurement updates

#### updates relative to 2.2/fb result

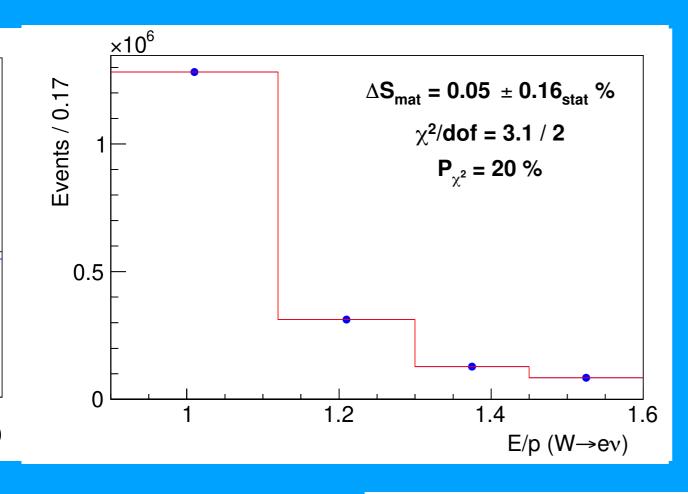

Method or technique	impact
Detailed treatment of parton distribution functions	+3.5  MeV
Resolved beam-constraining bias in CDF reconstruction	+10 MeV
Improved COT alignment and drift model [65]	uniformity
Improved modeling of calorimeter tower resolution	uniformity
Temporal uniformity calibration of CEM towers	uniformity
Lepton removal procedure corrected for luminosity	uniformity
Higher-order calculation of QED radiation in $J/\psi$ and $\Upsilon$ decays	accuracy
Modeling kurtosis of hadronic recoil energy resolution	accuracy
Improved modeling of hadronic recoil angular resolution	accuracy
Modeling dijet contribution to recoil resolution	accuracy
Explicit luminosity matching of pileup	accuracy
Modeling kurtosis of pileup resolution	accuracy
Theory model of $p_T^W/p_T^Z$ spectrum ratio	accuracy
Constraint from $p_T^W$ data spectrum	robustness
Cross-check of $p_T^Z$ tuning	robustness

## Muon momentum calibration

Aligning the drift chamber (the "central outer tracker" or COT)

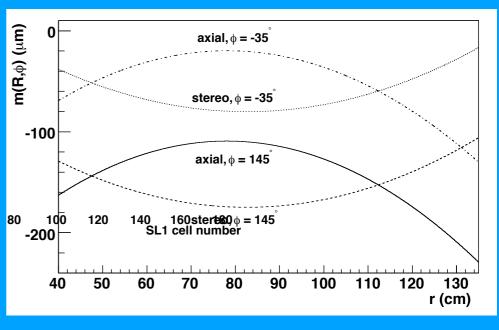

Two parameters for the electrostatic deflection of the wire within the chamber constrained using difference between fit parameters of incoming and outgoing cosmic-ray tracks

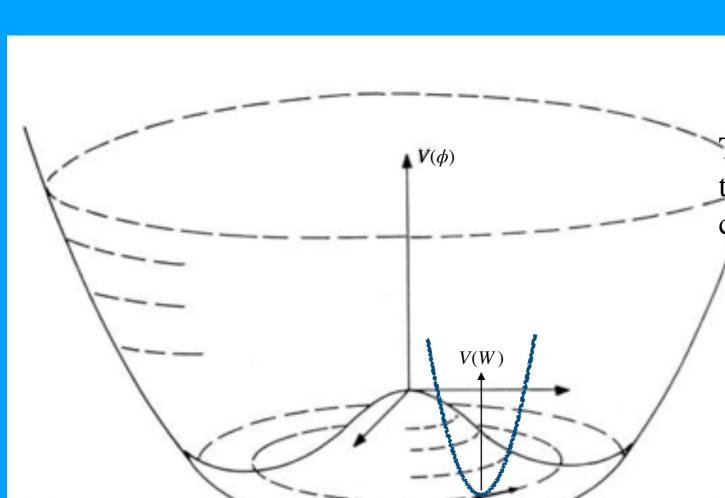

$$D\phi = (\partial_{\mu} + ieA$$

Higgs field potential

$$m_H = v\sqrt{2\lambda} = 125 \text{ GeV}$$
  $\lambda \approx 0.1$ 

W boson massno group indices, since it is a one-dir direction in spacetime, but it has a position in gro with location determined by its phase.

> The Lagrangian is simply the interacting scala by equation 4.6, Gauge field upotential  $F_{\mu\nu}F^{\mu\nu}$

$$\mathcal{L}(\phi) = \frac{1}{2} (D_{\mu} \phi^* D^{\mu} \phi + \mu^2 \phi^* \phi)$$

$$V = -\frac{g^2 v^2}{9} [(W_{\mu}^+)^2 + (W_{\mu}^-)^2]$$

 $\mathcal{L}(\phi) = \frac{1}{2} (D_{\mu} \phi^* D^{\mu} \phi + \mu^2 \phi^* \phi)$   $V = -\frac{g^2 v^2}{8} [(W_{\mu}^+)^2 + (W_{\mu}^-)^2]$ The minimum of  $V(\phi)$  has not changed, so again the vacuum and obtain the terms in equation 4.5 covariant derivative:

$$\mathcal{L}(\delta, \epsilon, A_{\mu}^{m_{W}}) = \frac{v}{2}g \quad \mathcal{L}_{\phi}(\delta, \epsilon) + \mathcal{L}_{A_{\mu}}(\delta, \epsilon, A_{\mu})$$

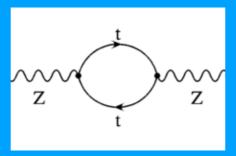

$$= m_{Z} = \frac{v}{2}\sqrt{e^{2}\mu^{2}g^{2}}$$

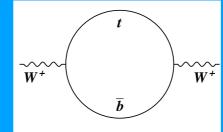

$$= \mathcal{L}_{\phi}(\delta, \epsilon) + \frac{v^{2}\mu^{2}g^{2}}{2\lambda}A_{\mu}A^{\mu} - \frac{e^{2}\mu^{2}}{2\lambda}A_{\mu}A^{\mu} - \frac{e^{2}\mu$$

There are a number of we markable phenomena in  $\frac{e^2\mu^2}{2\lambda}A_\mu A^\mu = e^2\langle\phi_0\rangle^2 A_\mu A^\mu$ . The non-zero expe tion in group space, i.e. it has a specific phase. with group positions along this specific phase, ov can imagine a source with a particular U(1) phase has a potential well in the direction  $\langle \phi_0 \rangle$ , the ph

## W boson mass

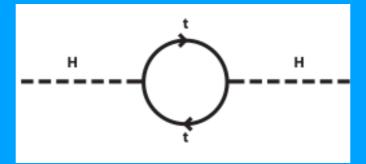

Gauge quantum corrections

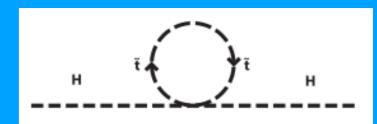

SM calculation: 80358 MeV

Higgs quantum corrections

Add supersymmetry

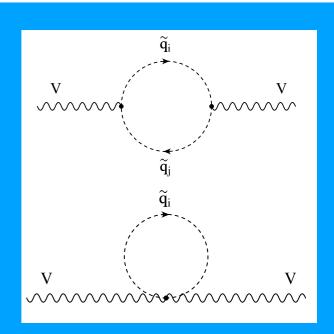

Naively integrating to a cutoff scale  $\Lambda$ :

$$\Delta m_H^2 = \frac{3g^2 m_t^2}{16\pi^2 m_W^2} \Lambda^2$$

If there is no new physics up to scale  $\Lambda$  then we need 'fine-tuning' to cancel the quantum corrections

1% fine tuning:  $\Lambda = 6.6$  TeV

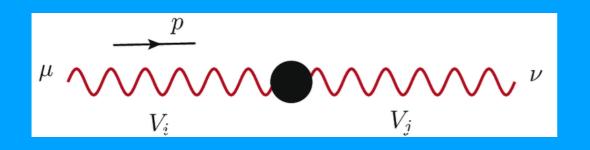

**Motivates TeV-scale new physics** 

### W boson mass

The SM effective field theory parameterizes general high-scale effects

$$\mathcal{L}_{SMEFT} = \mathcal{L}_{SM} + \mathcal{L}^{(5)} + \mathcal{L}^{(6)} + \mathcal{L}^{(7)} + \cdots, \qquad \mathcal{L}^{(d)} = \sum_{i=1}^{n_d} \frac{C_i^{(d)}}{\Lambda^{d-4}} Q_i^{(d)} \quad \text{for } d > 4.$$

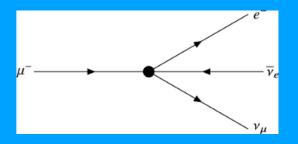

$$\frac{\delta m_W}{m_W} = \left(0.34 c_{HD} + 0.72 c_{HWB} + 0.37 c_{Hl3} - 0.19 c_{ll1}\right) \frac{v^2}{\Lambda^2}$$

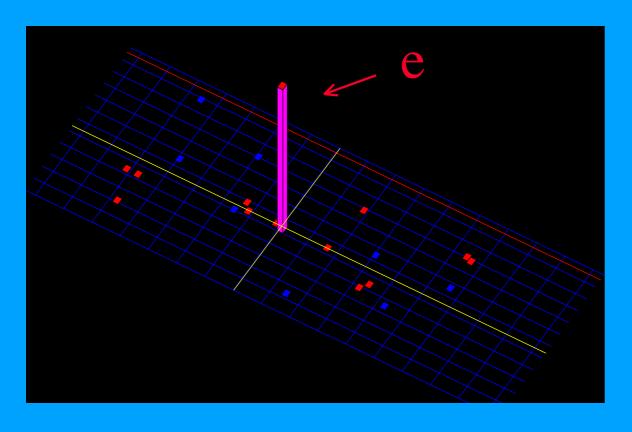

For 
$$\delta m_W/m_W=0.1\,\%$$
 and c<sub>HD</sub>=1,  $\Lambda=4.5\,{\rm TeV}$  e.g. Z' boson

For 
$$\delta m_W/m_W=0.1\,\%$$
 and chwb=1,  $\Lambda=6.6\,\mathrm{TeV}$  e.g. compositeness

Smaller  $c_i \rightarrow smaller \Lambda$ 

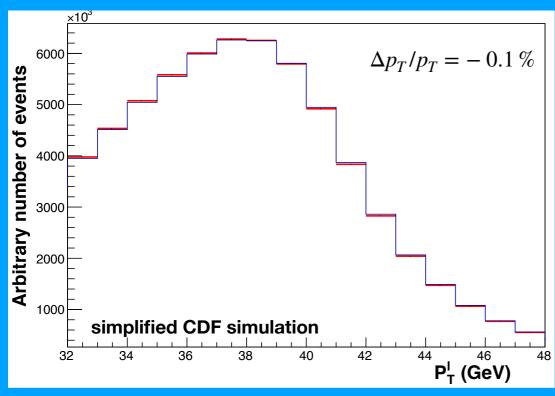

## **Calibrations**

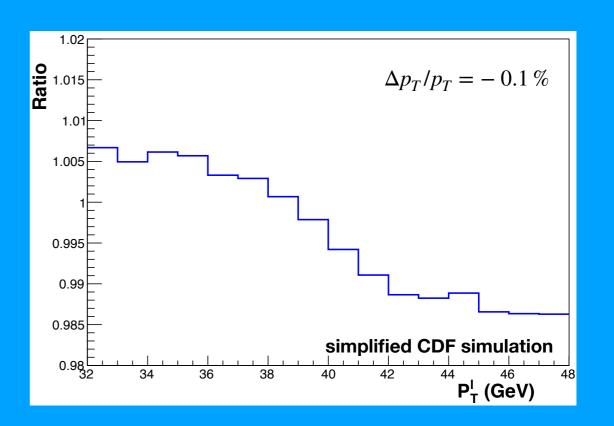

W bosons identified in their decay to  $e\nu$  or  $\mu\nu$ 

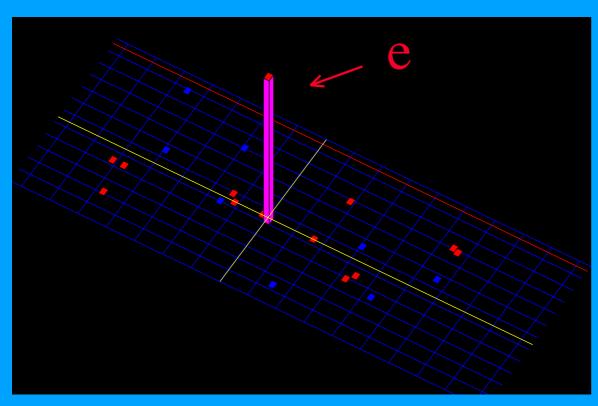

Measurement requires precise calibrations of momentum scale and resolution

Charged lepton scale:

## **Calibrations**

Measurement requires precise calibrations of momentum scale and resolution

$$\vec{p}_T = -(\vec{p}_T^{\ l} + \vec{u}_T)$$
