

Radio astronomy essentials: Pulsars and how to find them

MARCH 2026 @ UNDARK, ANNECY

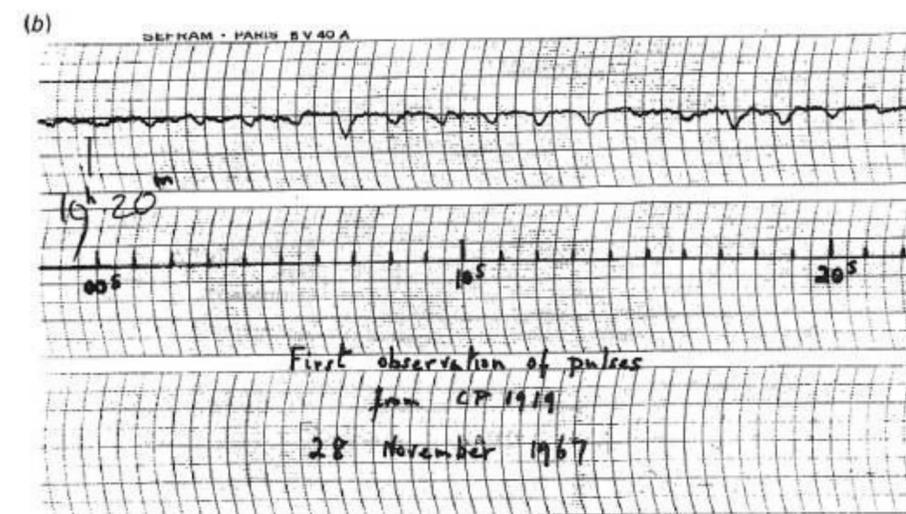

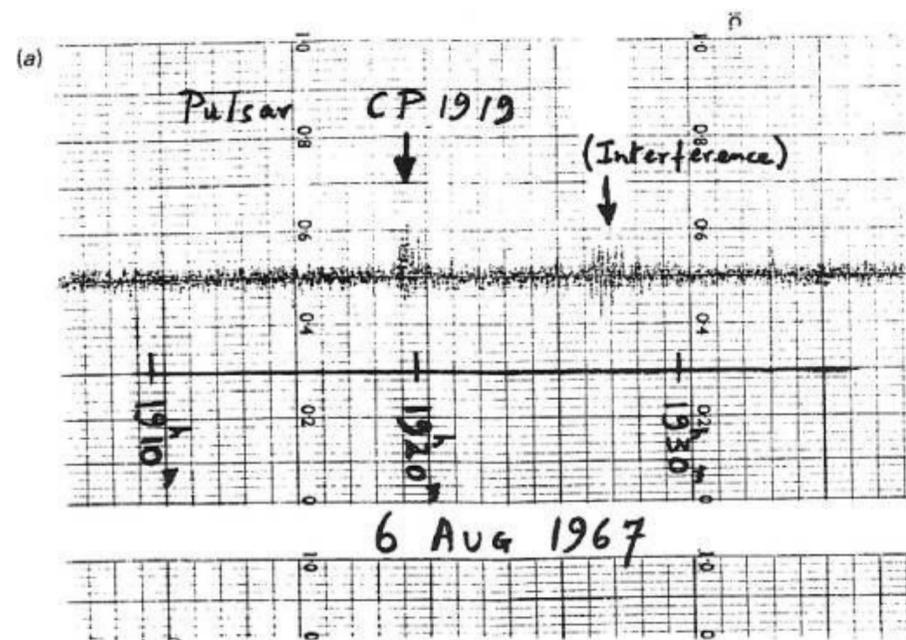

Cherry

NG-GUIHENEUF

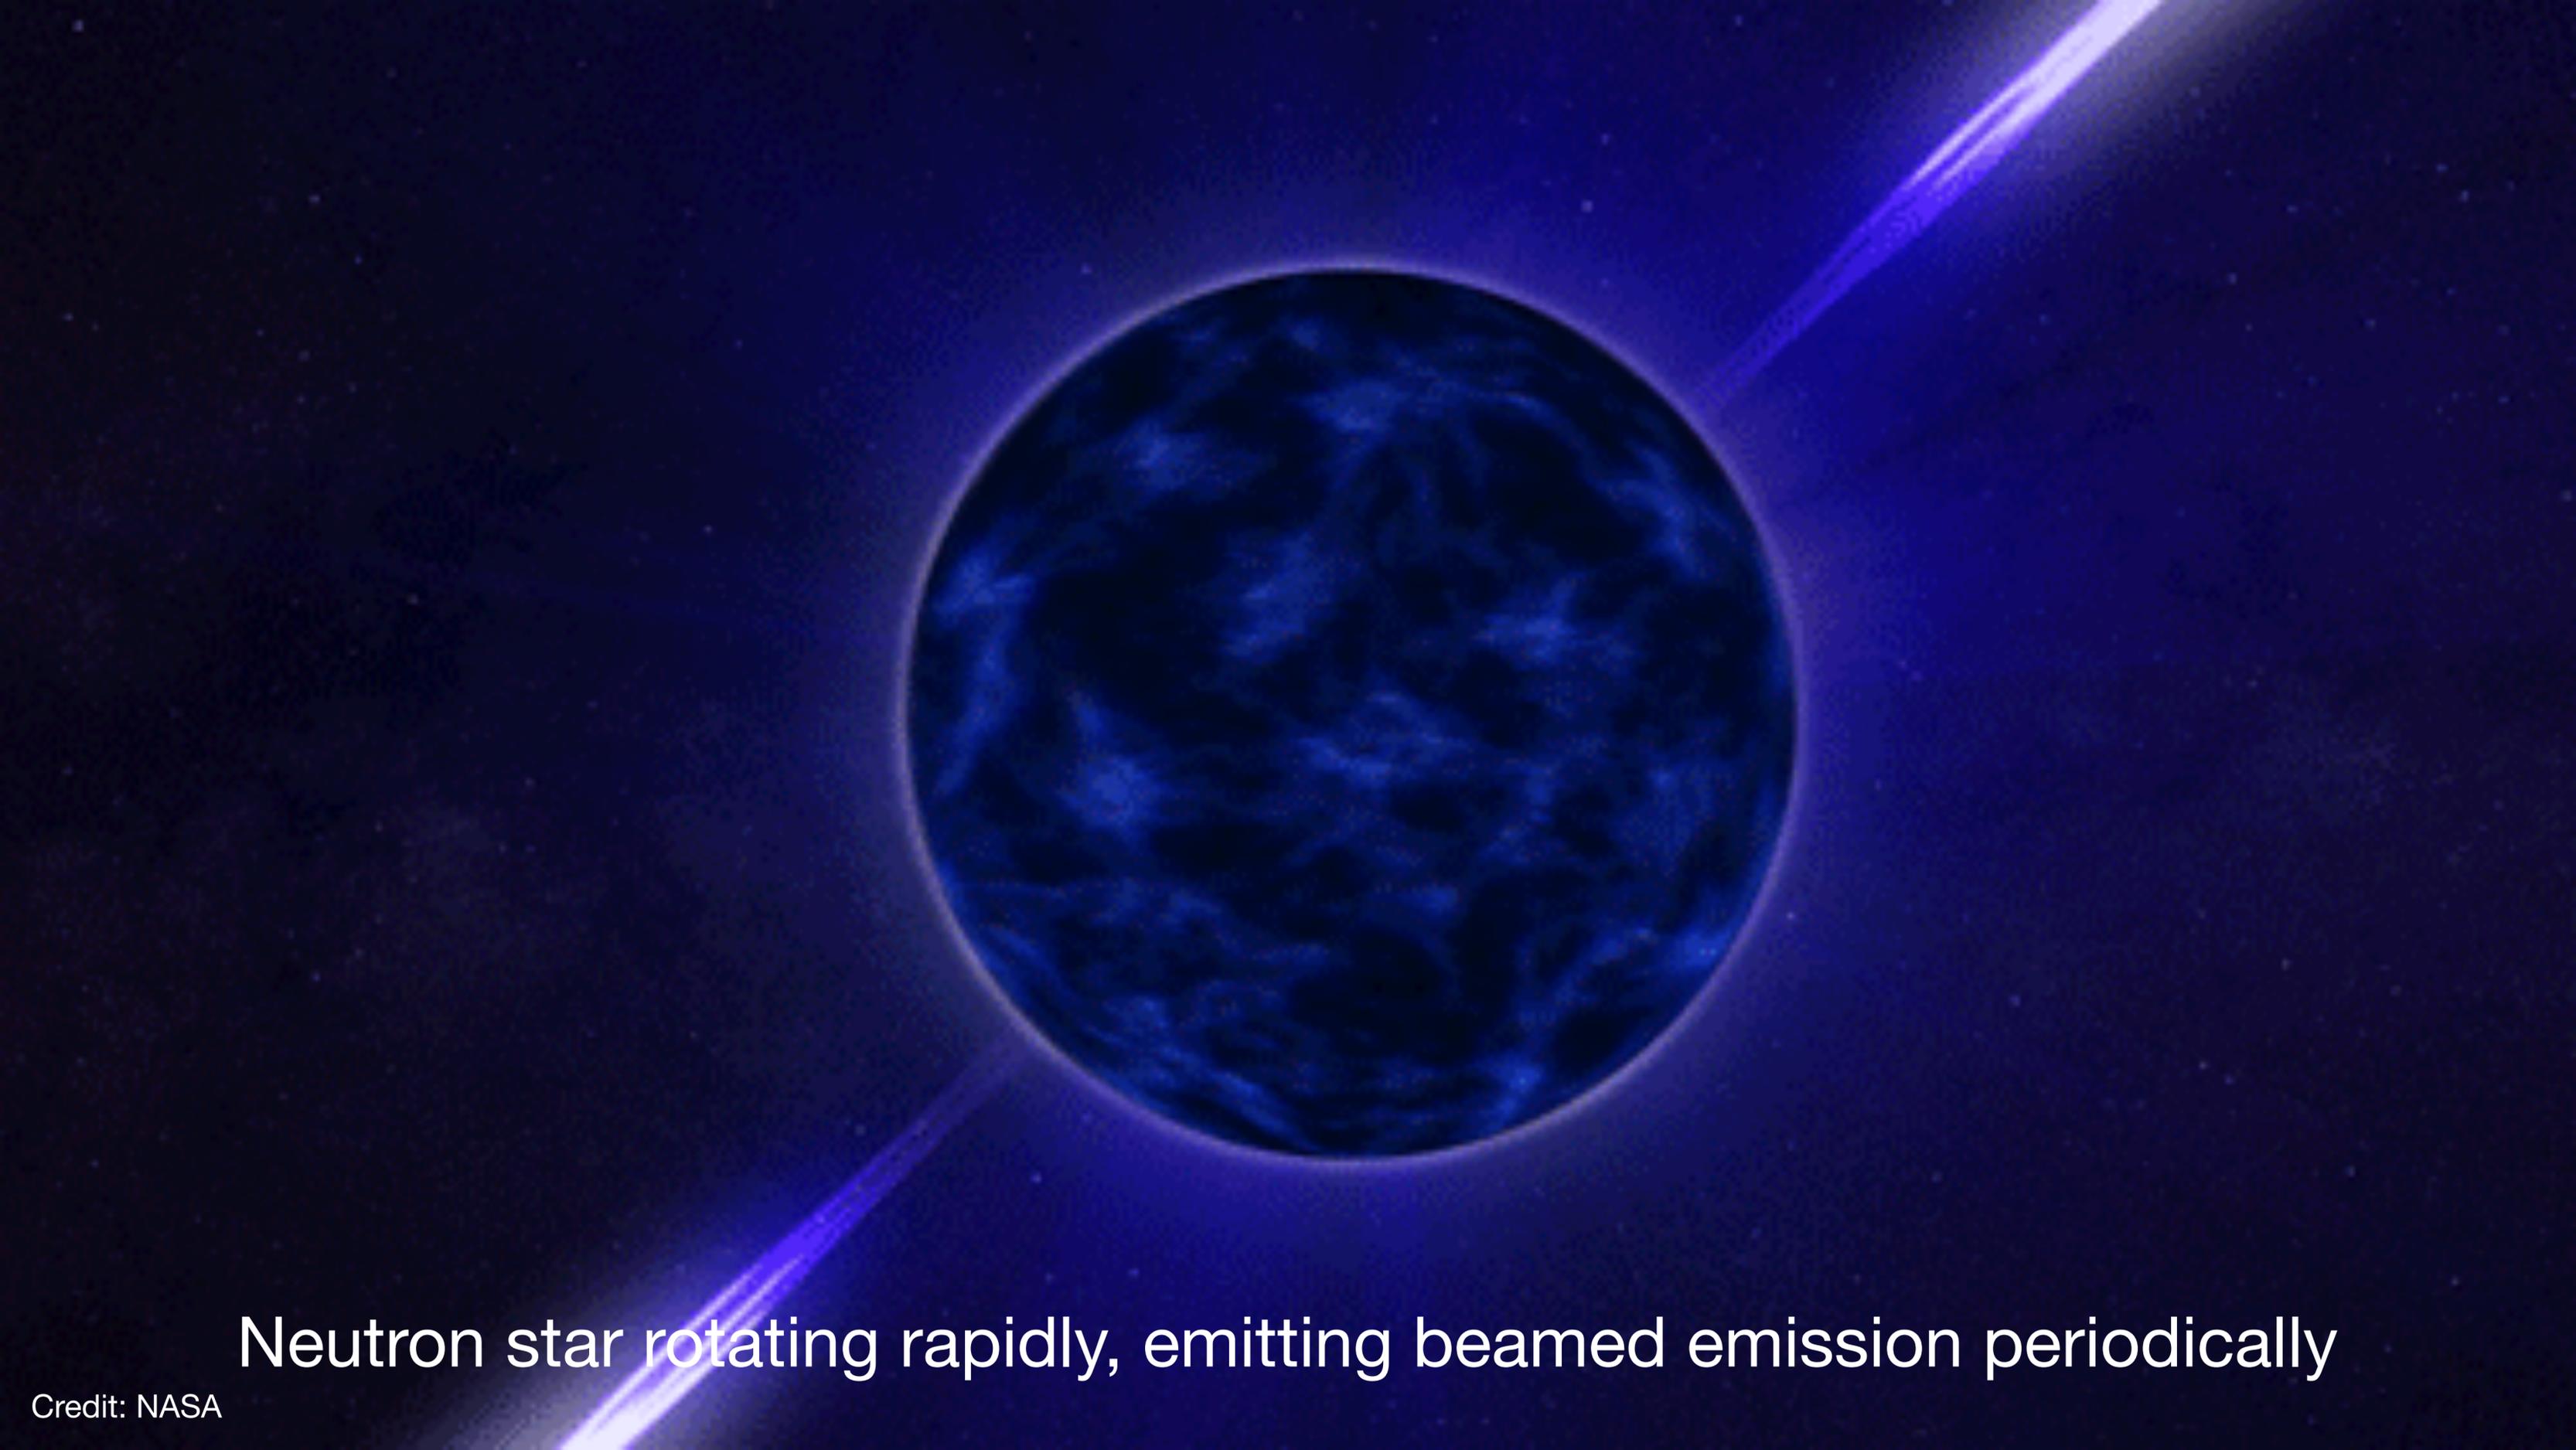

Pulsar discovered by Jocelyn Bell

- Discovery in **1967** by Jocelyn Bell Burnell and Antony Hewish.
- The first pulsar: **CP 1919** (now **PSR B1919+21**).
- Initial nickname: “**LGM-1**” (**Little Green Men**) because of the extremely regular pulses.

Data rate: tens of meters of paper per day

Neutron star rotating rapidly, emitting beamed emission periodically

Supernova explosion at the end of life of a massive star

Why does it spin so fast?

LAPTh

A hand in a white space suit glove holds a silver spoon. On the spoon's bowl sits a small, glowing blue and white sphere representing Earth. The background is a dark, star-filled space. The text at the bottom provides a weight comparison for the Earth.

6 billion tonnes = Mount Everest = 3 million elephants

Radio pulsars is a geometric effect.

Pulsars in a nutshell

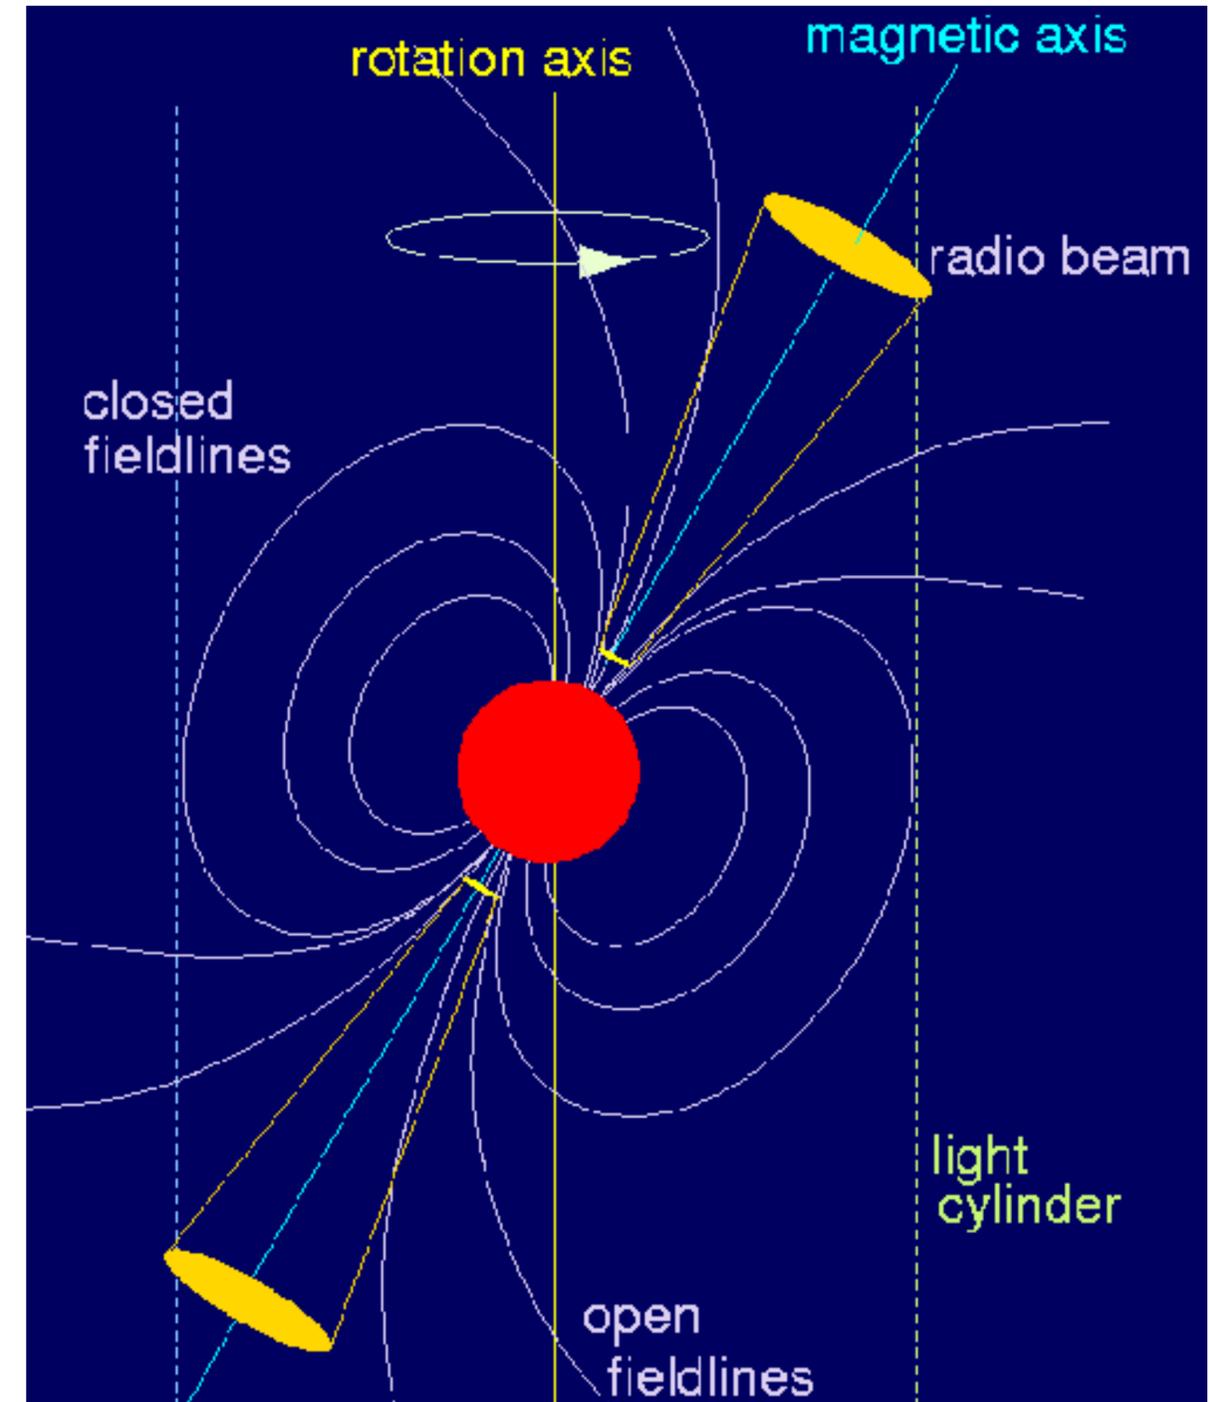

- Rapidly rotating Neutron Stars
- Radius ~ 10 km, mass ~ 1.4 solar mass
- \rightarrow central densities: order of a billion tons / cm^3
- Highly magnetized ($10^8 \sim 10^{14}$ Gauss)
- \rightarrow emit steep spectrum radio emission aligned with β -field axis
- Misalignment of rotational and β -axes \rightarrow periodic signals

Large mass \rightarrow Consequent rotational stability \rightarrow Accurate clocks
 \rightarrow Many astrophysical applications

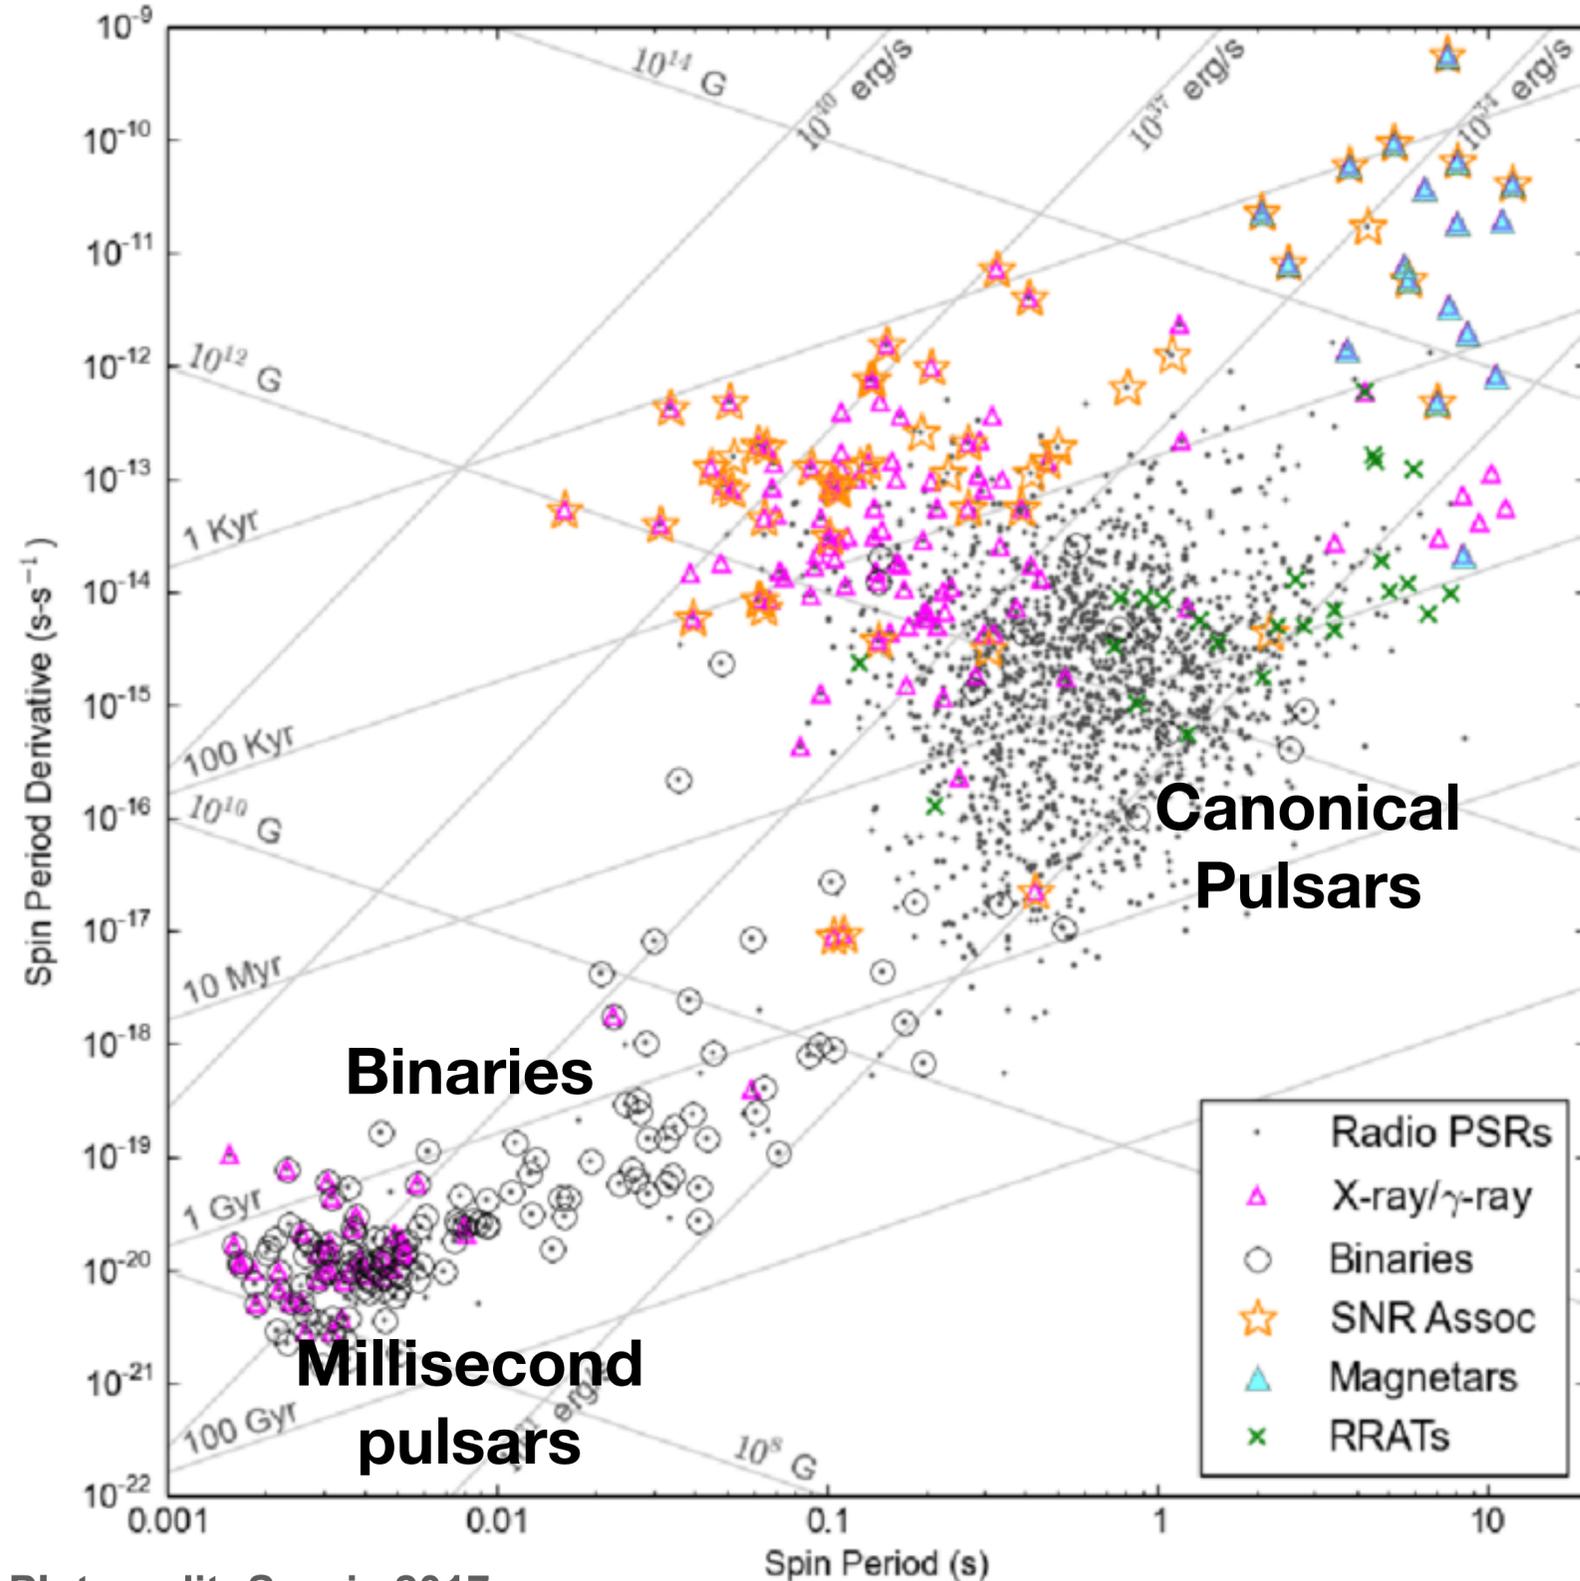

Light cylinder

- Radio emission comes from **magnetic polar regions**
 - enormous electric fields accelerate particles
 - these particles produce **electron–positron pairs**
 - the plasma generates the **coherent radio emission** we observe. (c.f. yesterday's lecture)
- Beam sweeps across Earth → pulses
- **light cylinder radius:** where co-rotation would require the speed of light. Outside: Open field lines and particles escape
- magnetic field is not aligned with the rotation axis, so as the star rotates, the magnetic field structure is **continually changing in time** → radiates energy away → **spins down**
- We know pulsars are rotation-powered because they steadily lose rotational energy, and that lost energy exactly matches the power carried away by their radiation and particle winds.

Characteristic ages

$$\tau_c \equiv \frac{P}{2\dot{P}} \simeq 15.8 \text{ Myr} \left(\frac{P}{\text{s}} \right) \left(\frac{\dot{P}}{10^{-15}} \right)^{-1}$$

If the pulsar had been slowing at the same rate its entire life, how long would it take to reach its current spin?

Surface Magnetic field strength

$$B_{\text{surf}} = 3.2 \times 10^{19} \text{ G} \sqrt{P\dot{P}} \simeq 10^{12} \text{ G} \left(\frac{\dot{P}}{10^{-15}} \right)^{1/2} \left(\frac{P}{\text{s}} \right)^{1/2}$$

Pulsars with strong magnetic fields slow down faster (stronger radiation, more outflow)

Death lines

$$B \lesssim 10^{12} \text{ G} \left(\frac{P}{1 \text{ s}} \right)^2$$

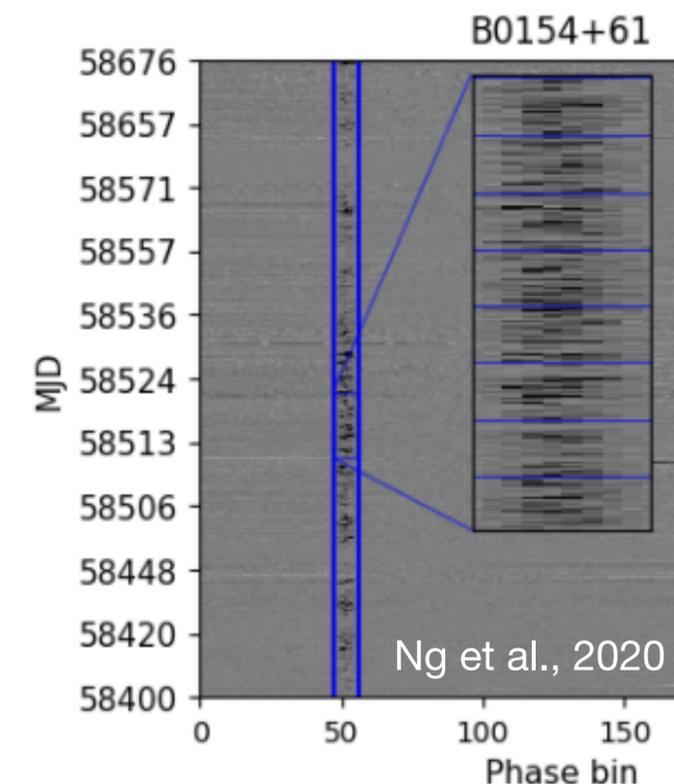

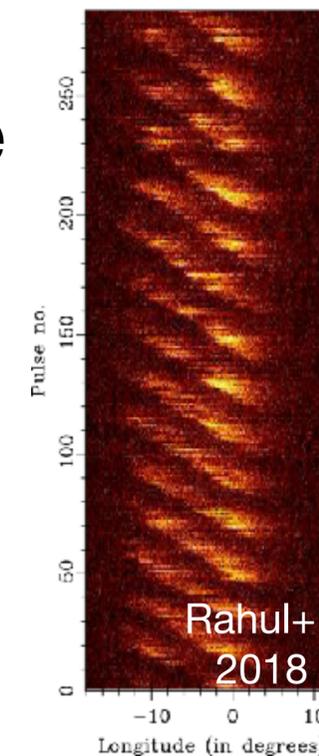

Critical value ($\sim 10^{12} \text{ G}$) needed to trigger pair creation, beyond that, rotation too slow to sustain the plasma needed for radio emission

Some more on emission mechanisms

- **Coherent emission:** The exact mechanism is still debated:
 - **curvature radiation from bunched particles** — Requires highly ordered bunching, hard to justify dynamically. Doesn't naturally produce the observed microstructure and subpulse variability
 - **plasma instabilities:** Explains rapid variability, Growth rates too slow to explain the brightness and short pulse widths. Difficult to produce narrow emission cones

- **Nulling:** constrains **magnetospheric models**—the engine driving the emission must be able to switch states rapidly.

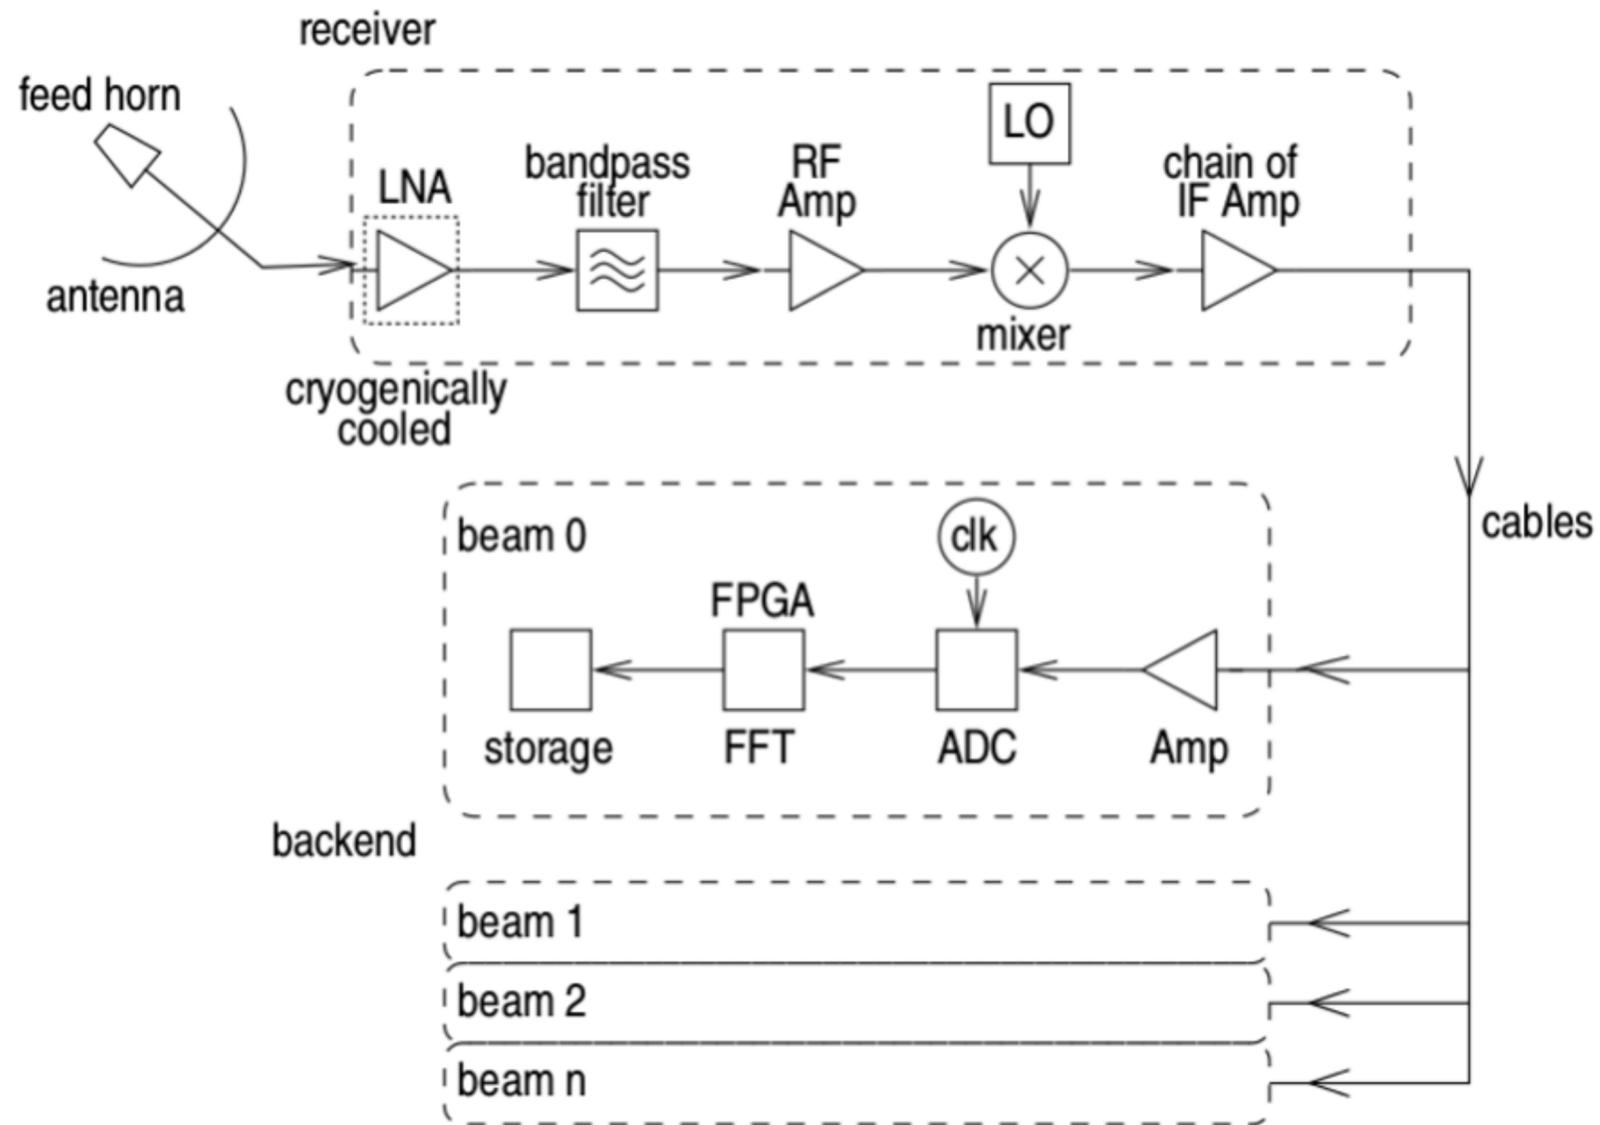

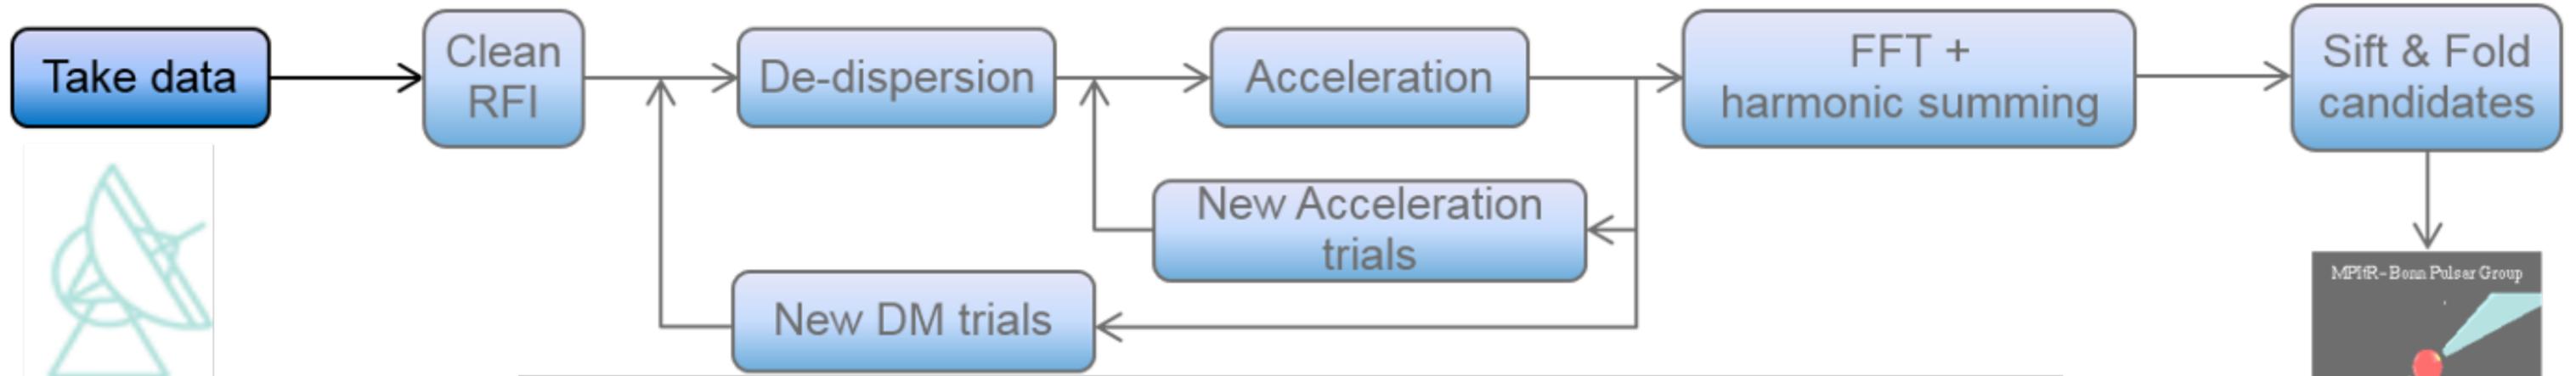

- **Subpulse drifting:** components move systematically in phase. Emission comes in organized sub-beams; shows plasma circulation patterns near the polar cap.

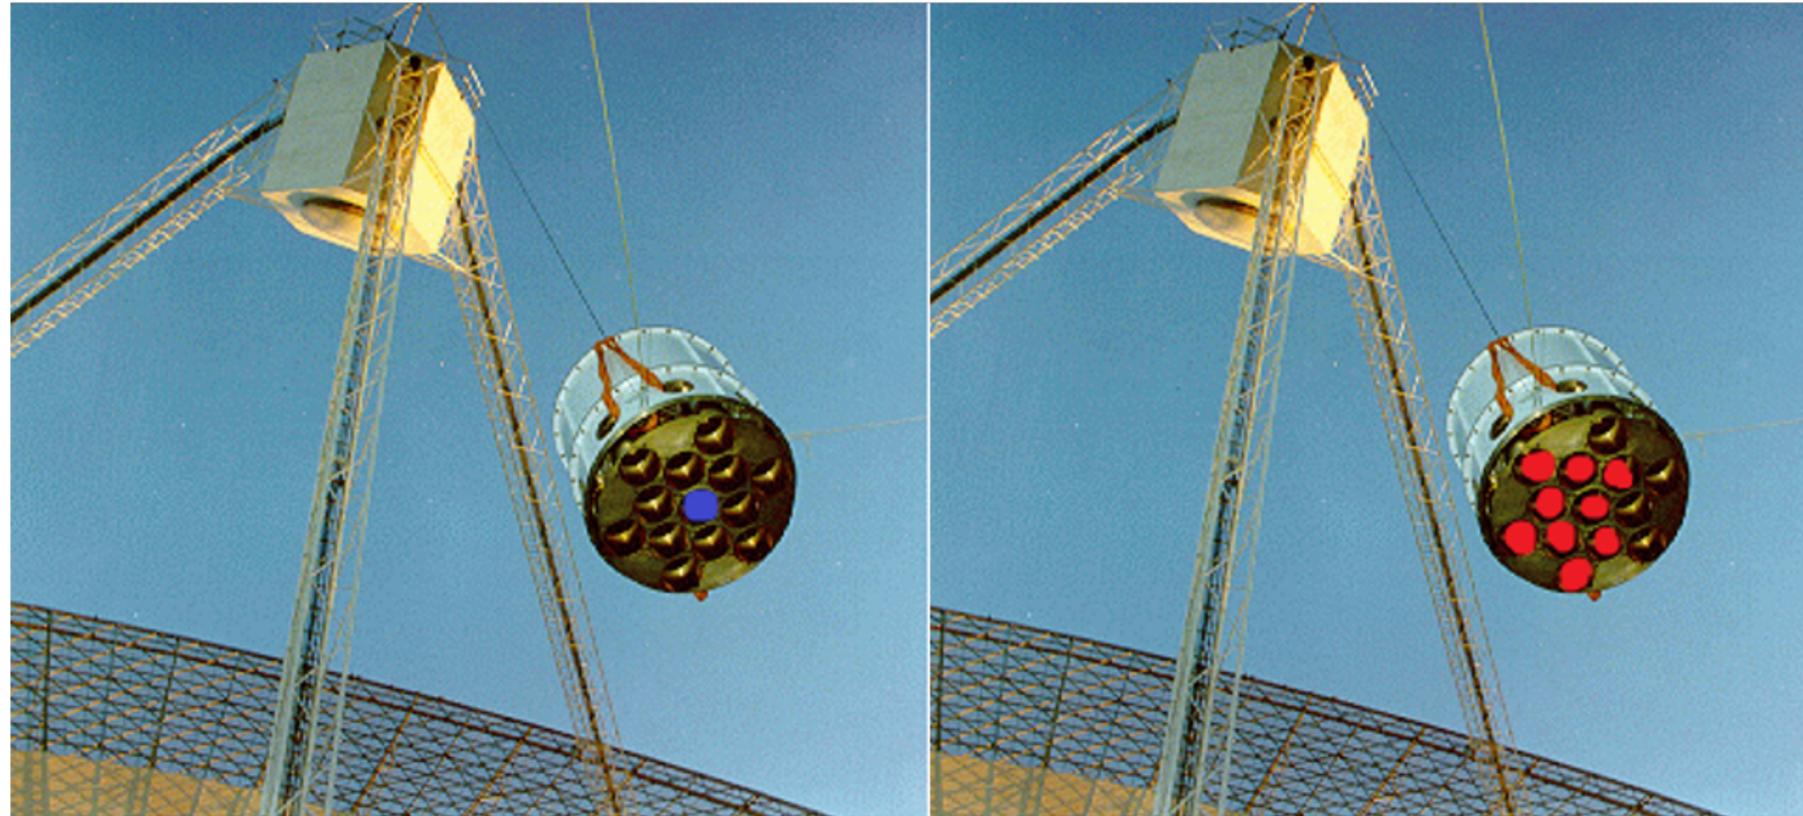

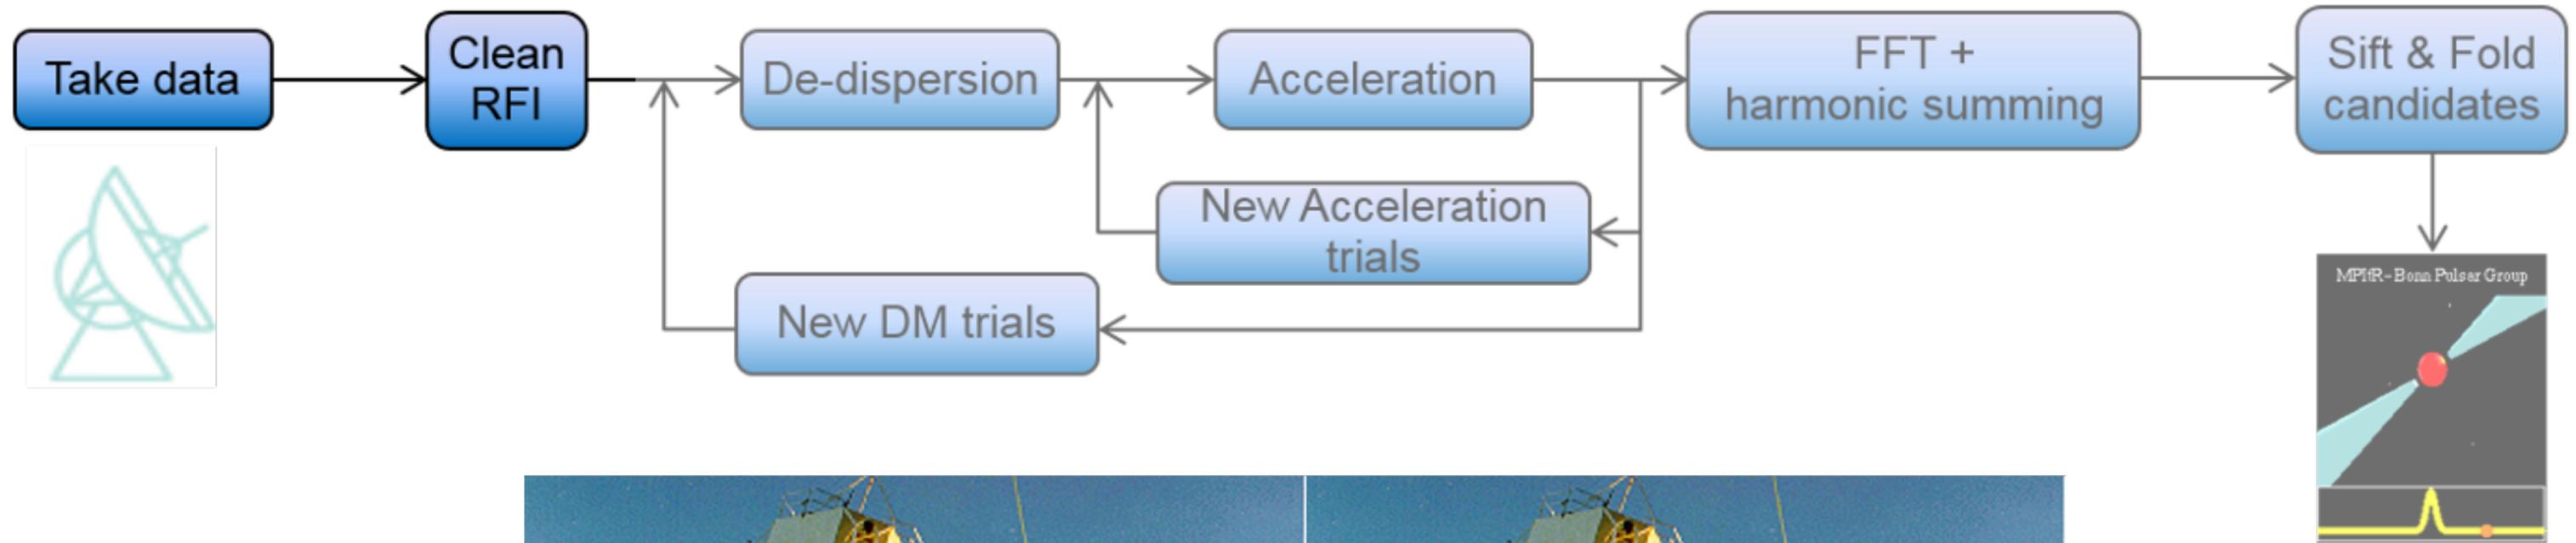

Pulsar searching

How do we find them?

Pulsar searching by periodicity

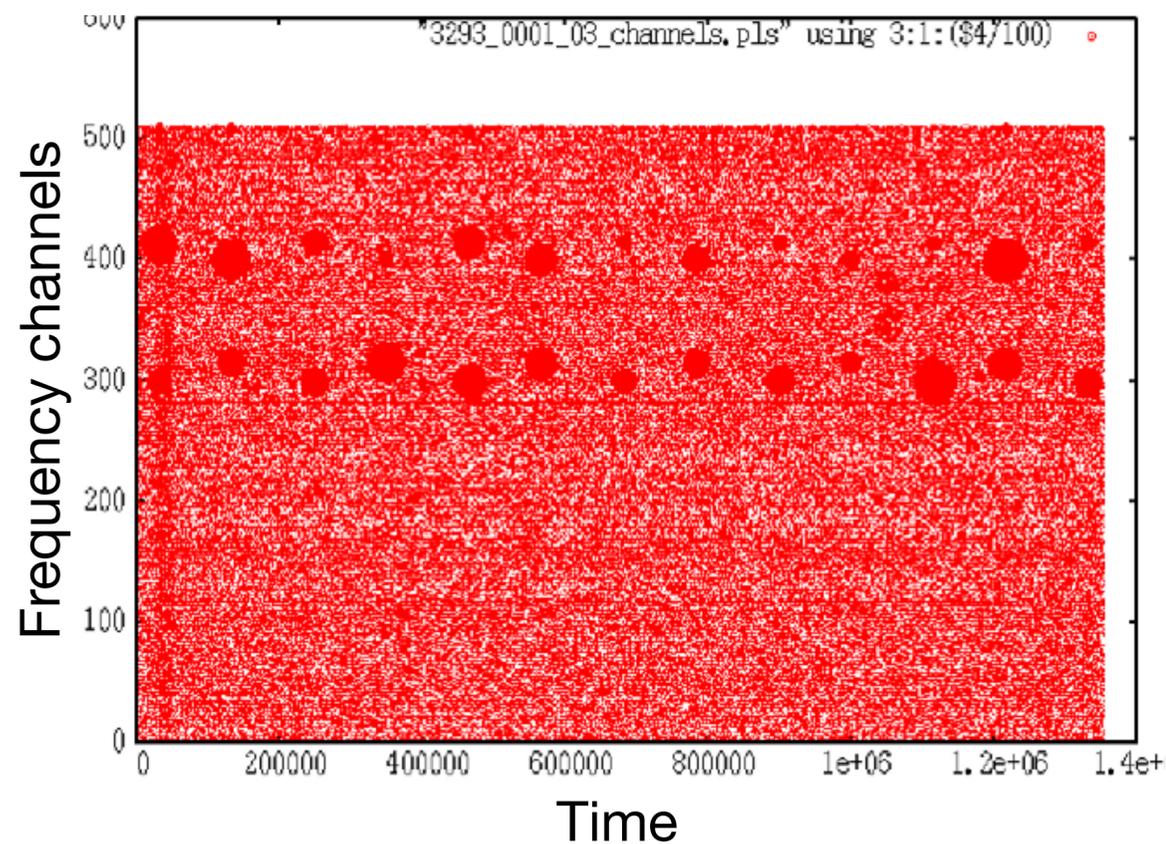

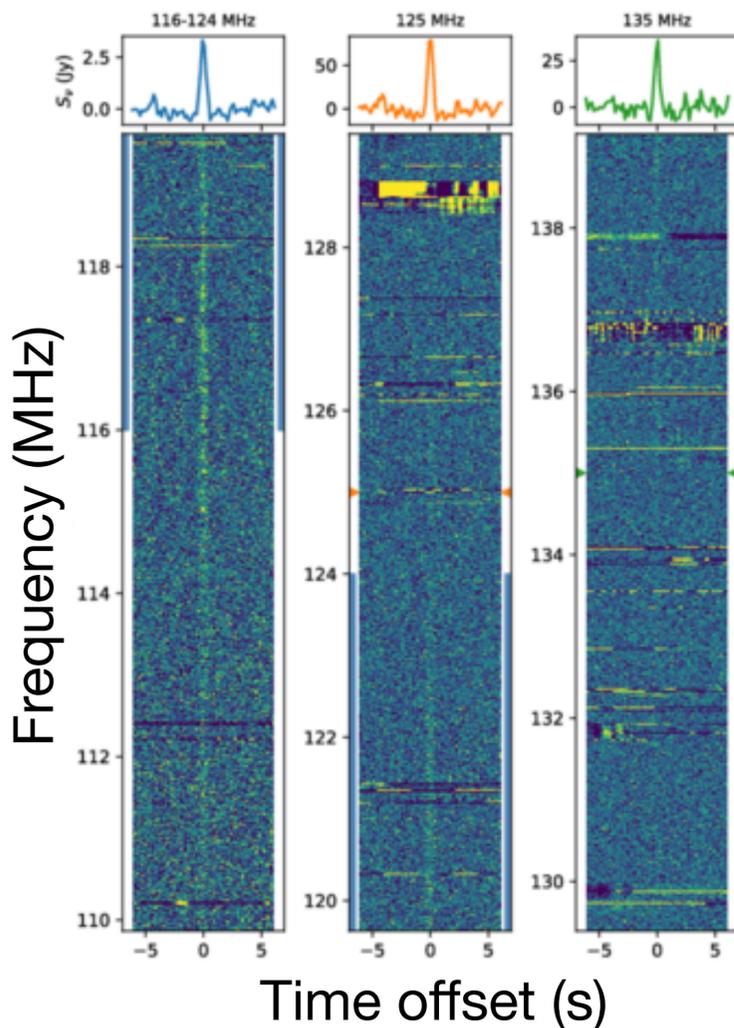

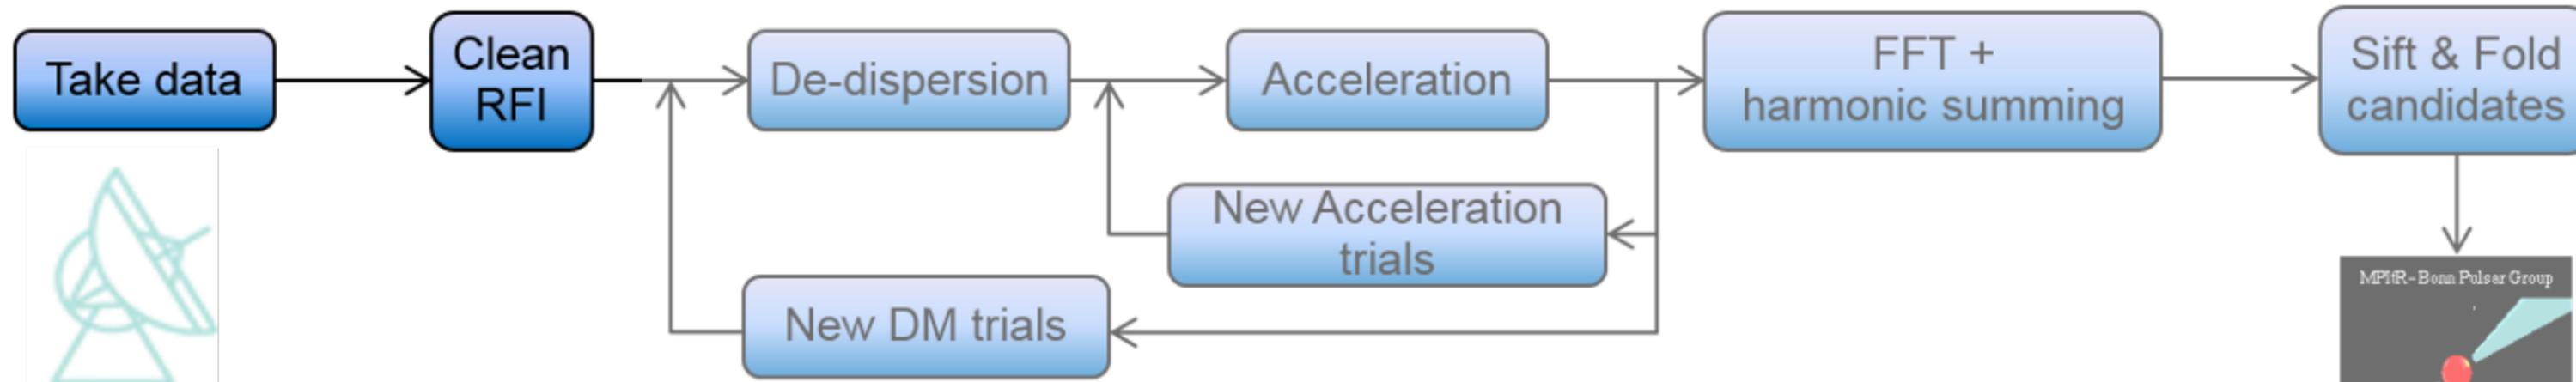

Pulsar searching by periodicity

Celestial signal – single receiver beam

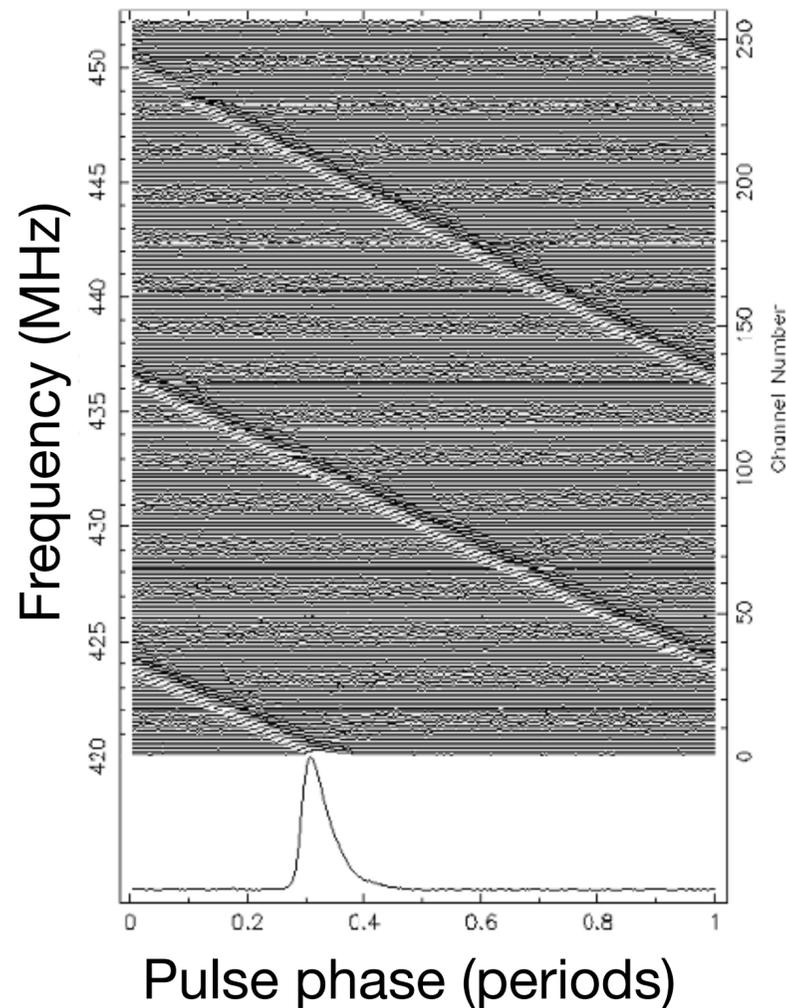

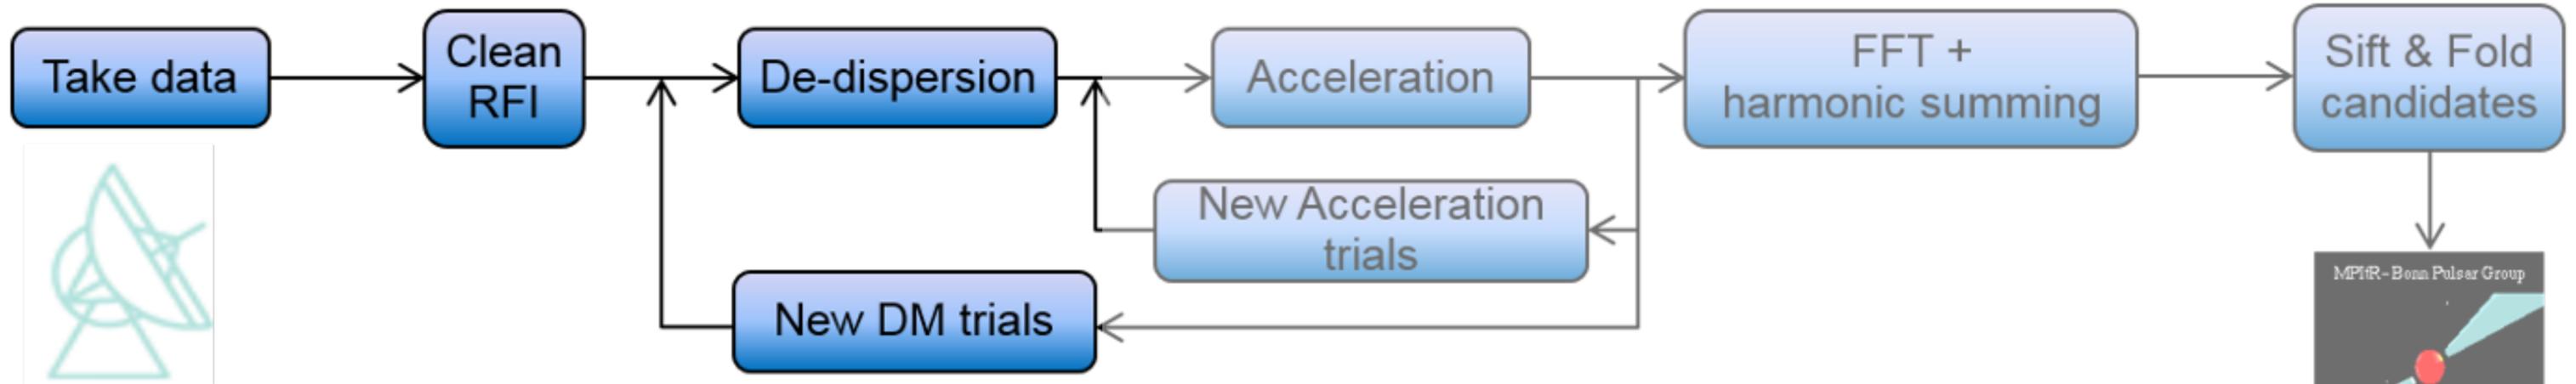

Terrestrial RFI – Multiple receiver beams

Pulsar searching by periodicity

- Can be narrow band in frequency
- Time domain impulsive RFI
- Periodic RFI
- Strategy: threshold, kurtosis...
- Replace with Gaussian / running mean but be careful not to introduce artifacts

Pulsar searching by periodicity

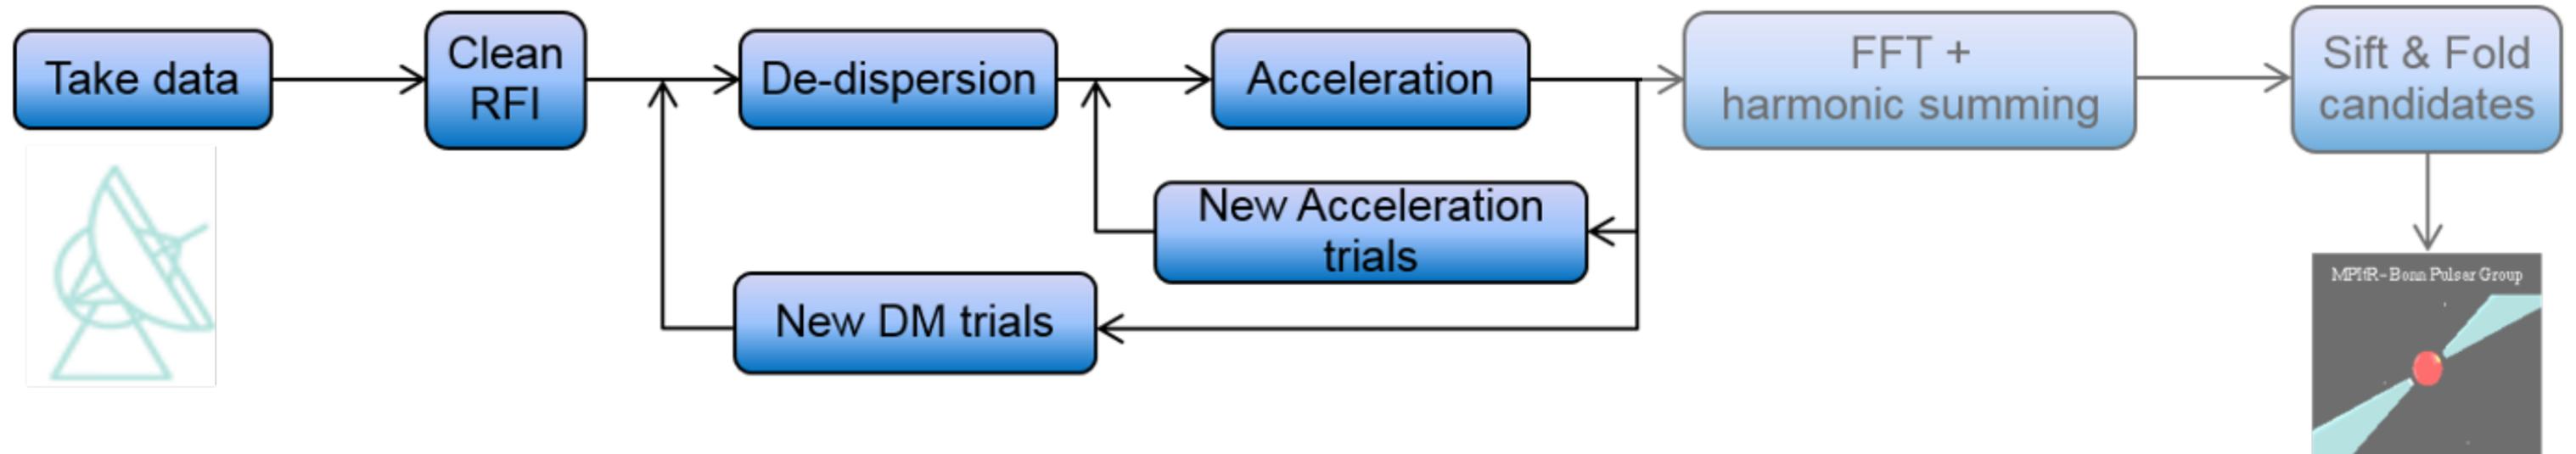

The pulse travel time (t_p) of an EM wave of freq ν emitted at a distance d propagating through an electron plasma with uniform number density n_e :

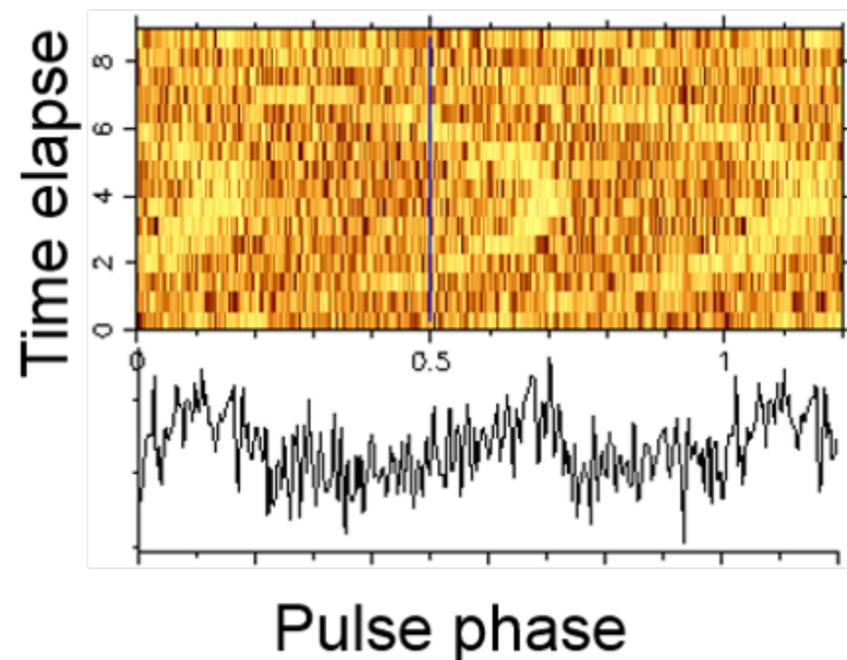

**Dispersion
measure (DM)**

$$t_p = \frac{d}{c} + \frac{e^2}{2\pi m_e c} \int_0^d n_e dl$$

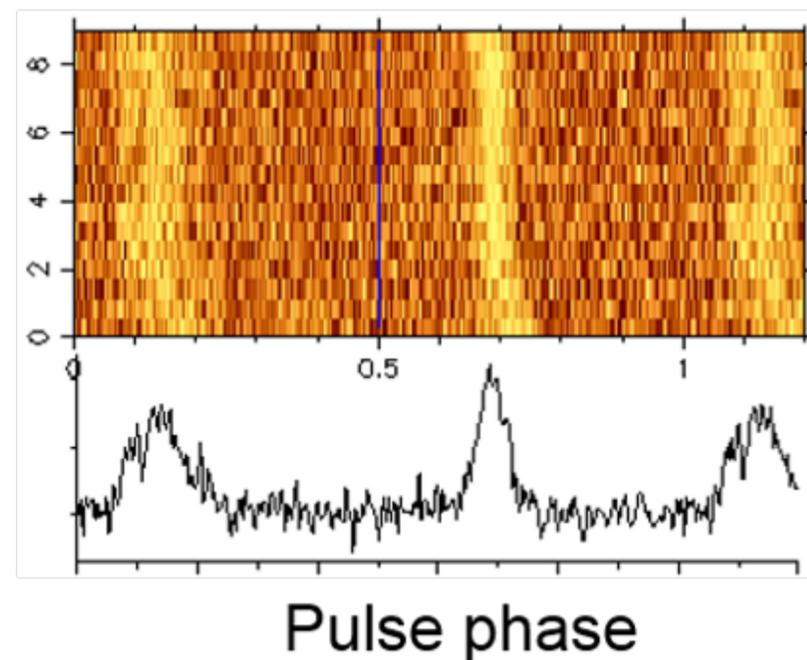

Pulsar searching by periodicity

No acceleration correction

Linear acceleration approx.

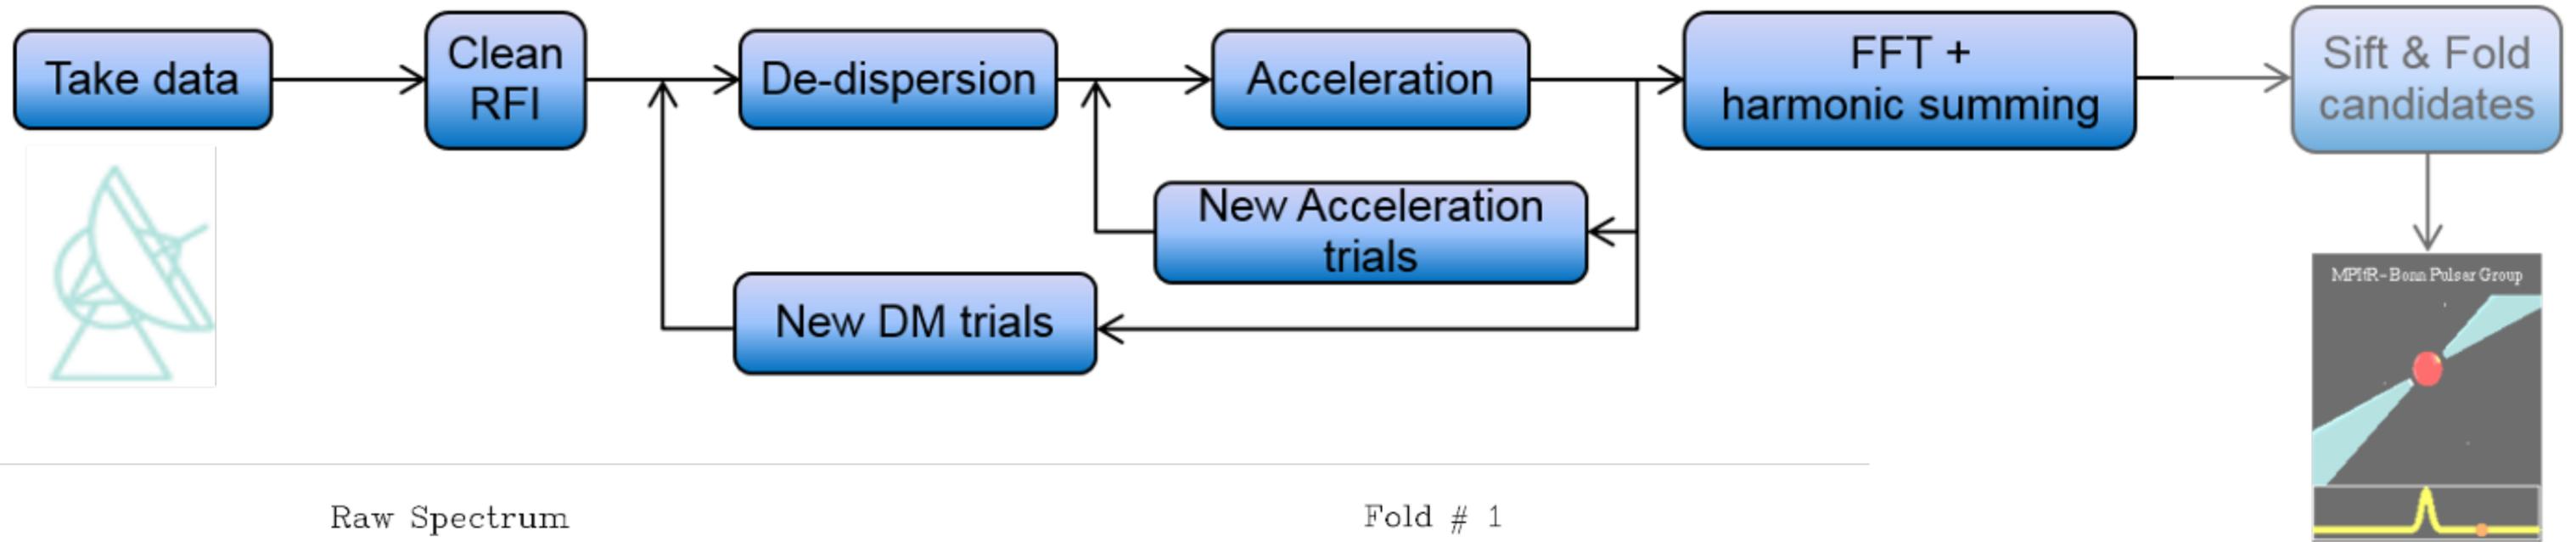

- Resampling in time to restore to rest frame of the pulsar
- Solving for full orbit too expensive
—> linear acceleration approximate
- For circular orbit, timing $y(t)$ is approx. a sinusoid with period equal to the orbital period (P_b) and amplitude (A) equal to the projected semi-major axis: $y(t) = A \sin(2\pi \frac{t}{P_b} + \phi) + C$

A = amp_guess
 P_b = pb_guess
 Phi = phase_guess
 C = offset_guess

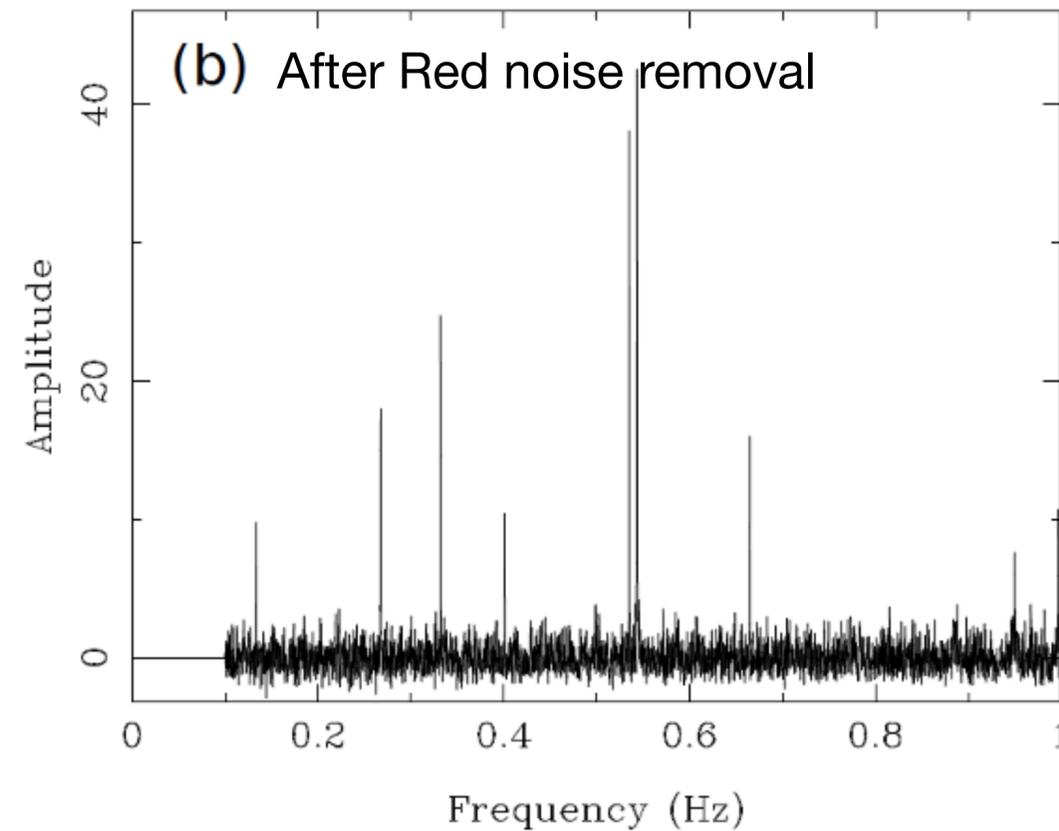

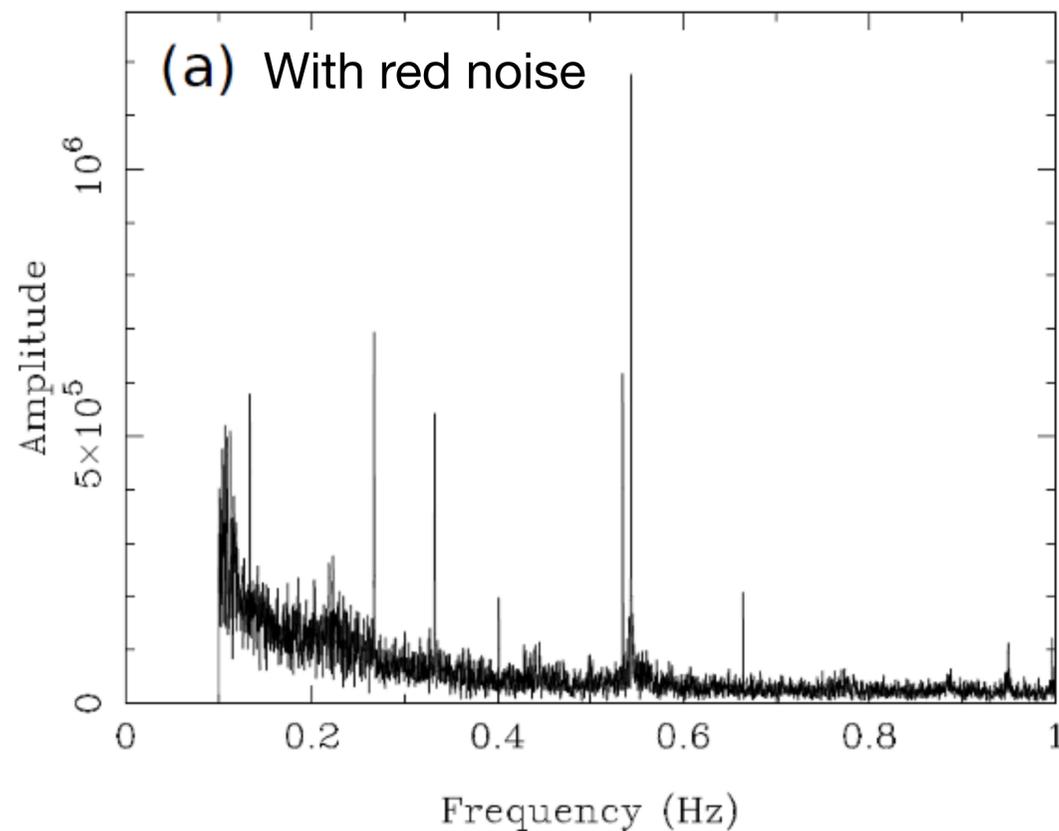

This is the 2nd exercise in the hands-on session this afternoon

Pulsar searching by periodicity

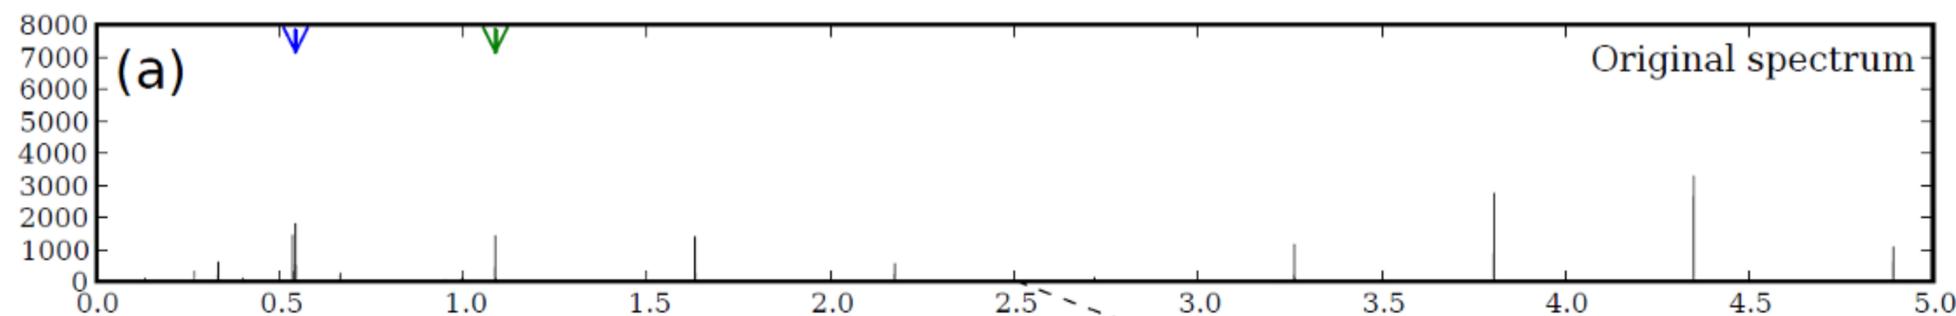

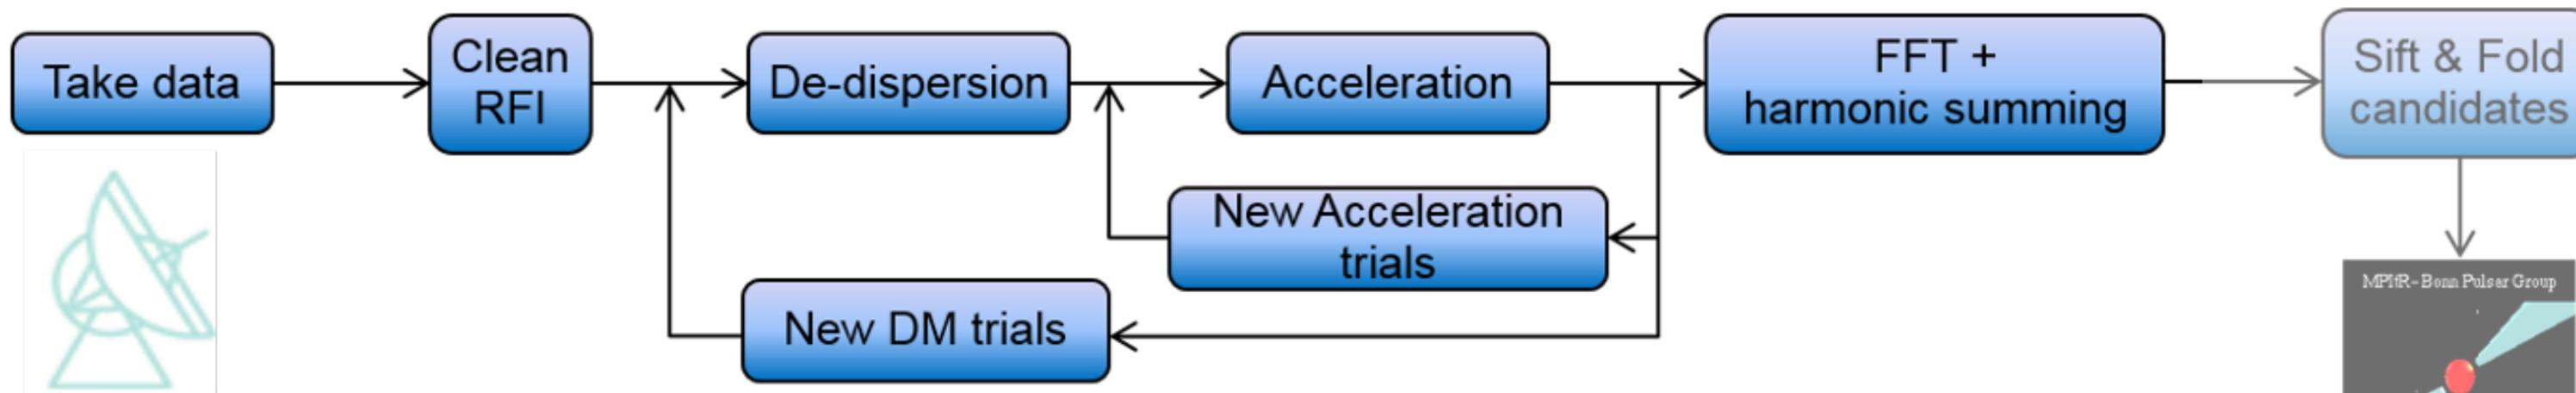

Raw Spectrum

Fold # 1

This is the 2nd exercise in the hands-on session this afternoon

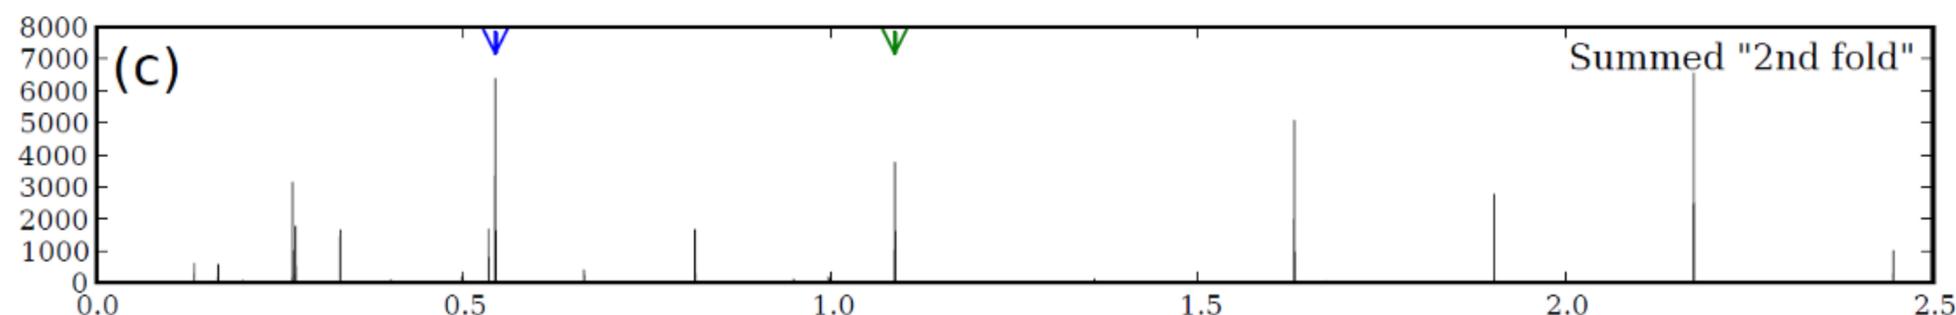

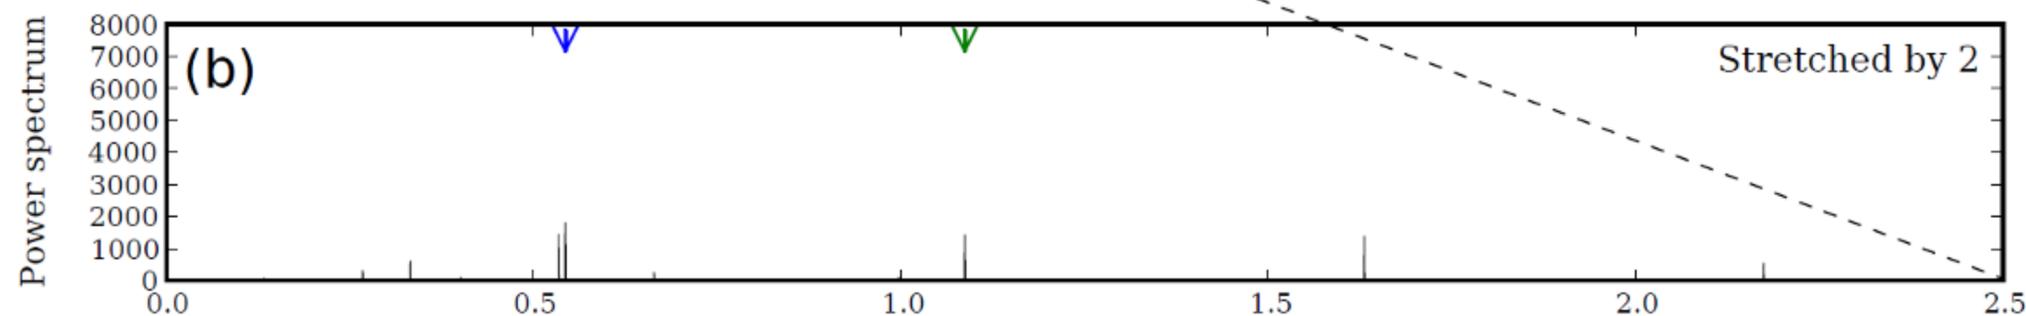

Pulsar searching by periodicity

- Pulses Are narrow, Not sinusoidal

- Their power is spread over many **harmonics** in the Fourier spectrum, and incoherent harmonic summing recombines that distributed power to improve detectability.

- After rescaling, the harmonics **line up at the same frequency**, and their power can be (incoherently) summed.

Fourier frequency (Hz)

Timing Array

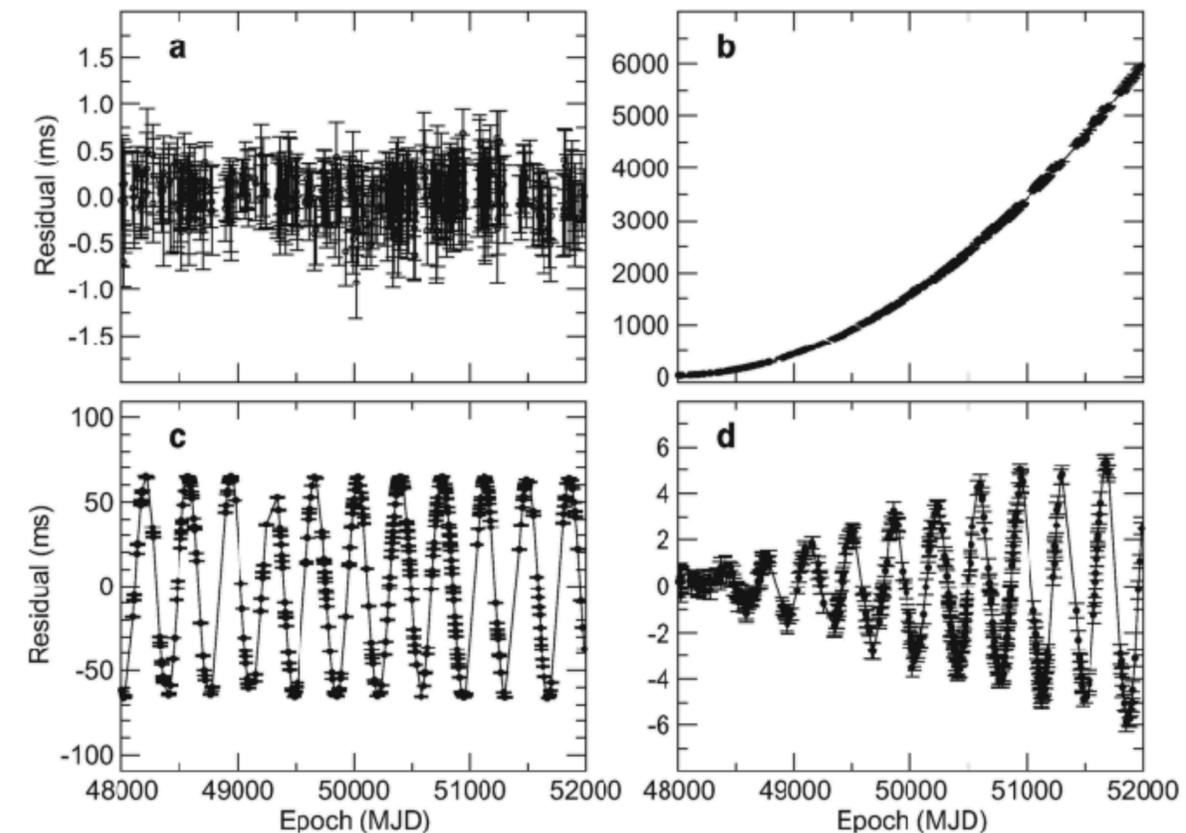

Pulsars timing in a nutshell

- Unambiguously account for every rotation of a pulsar
- TOAs: Times of Arrival
- Measurement - Model = Timing Residuals

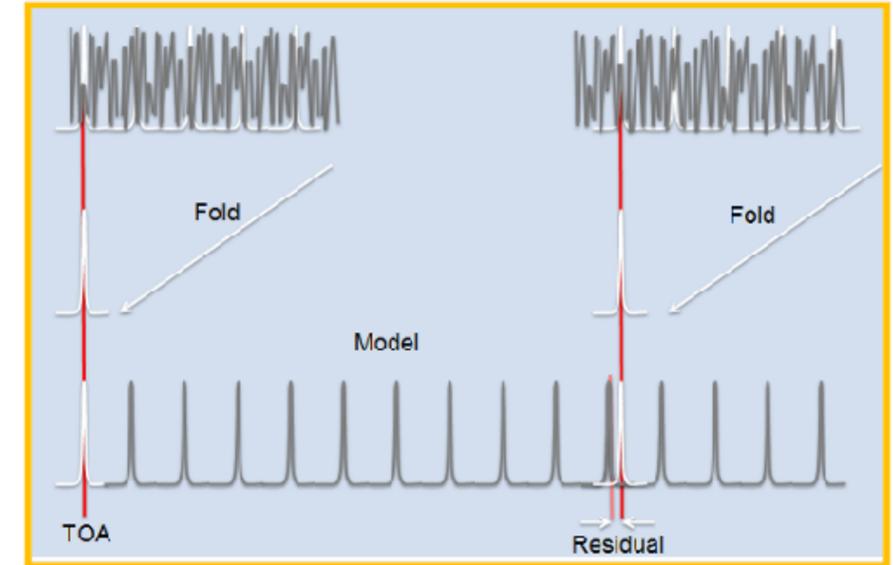

- Isolated pulsars have 4 timing parameters: RA, Dec, P, P-dot
- Extended timing can give Proper motion & parallax
- Binary pulsars add 5 Keplerian Orbital params: P_{orb} , $asini/c$, e , ω , T_0
- Some binaries give post-Keplerian param: $\dot{\omega}$, γ , \dot{P}_{orb} , r , s

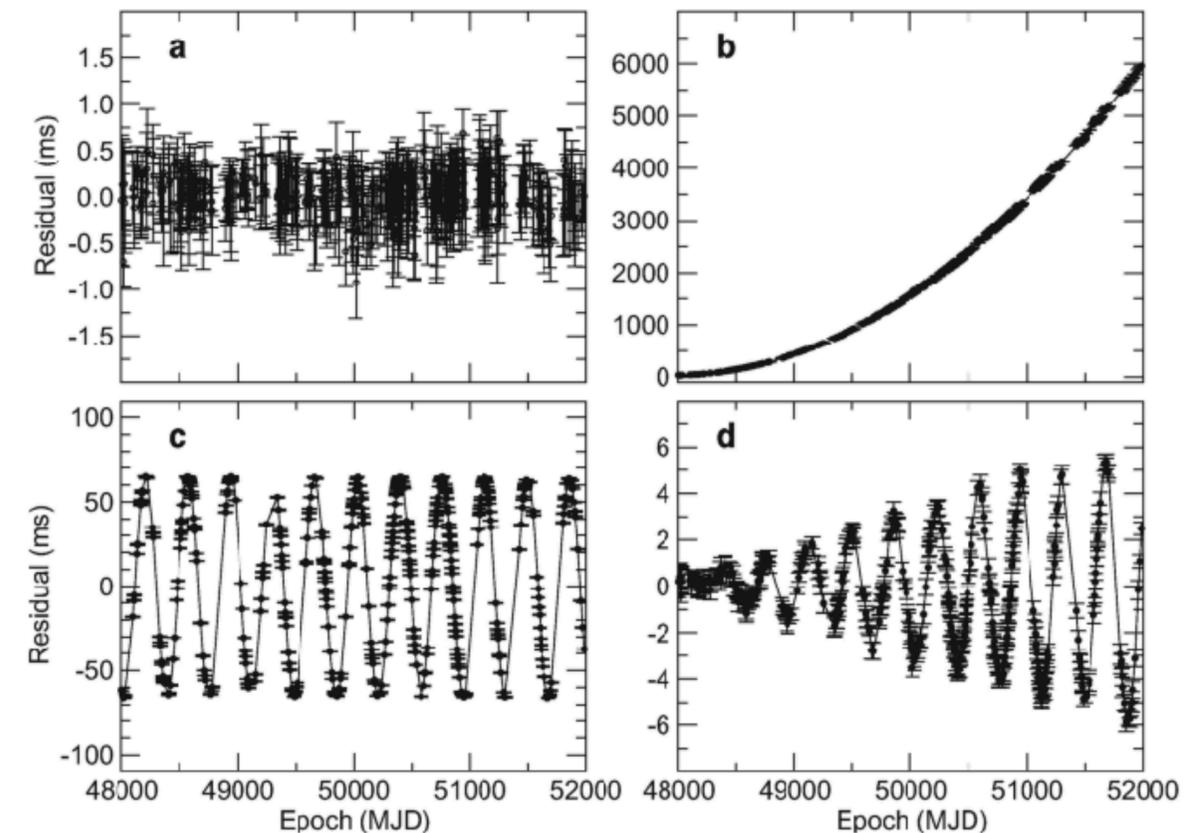

Pulsars timing in a nutshell

- Unambiguously account for every rotation of a pulsar
- TOAs: Times of Arrival
- Measurement - Model = Timing Residuals

As Michael Kramer says:

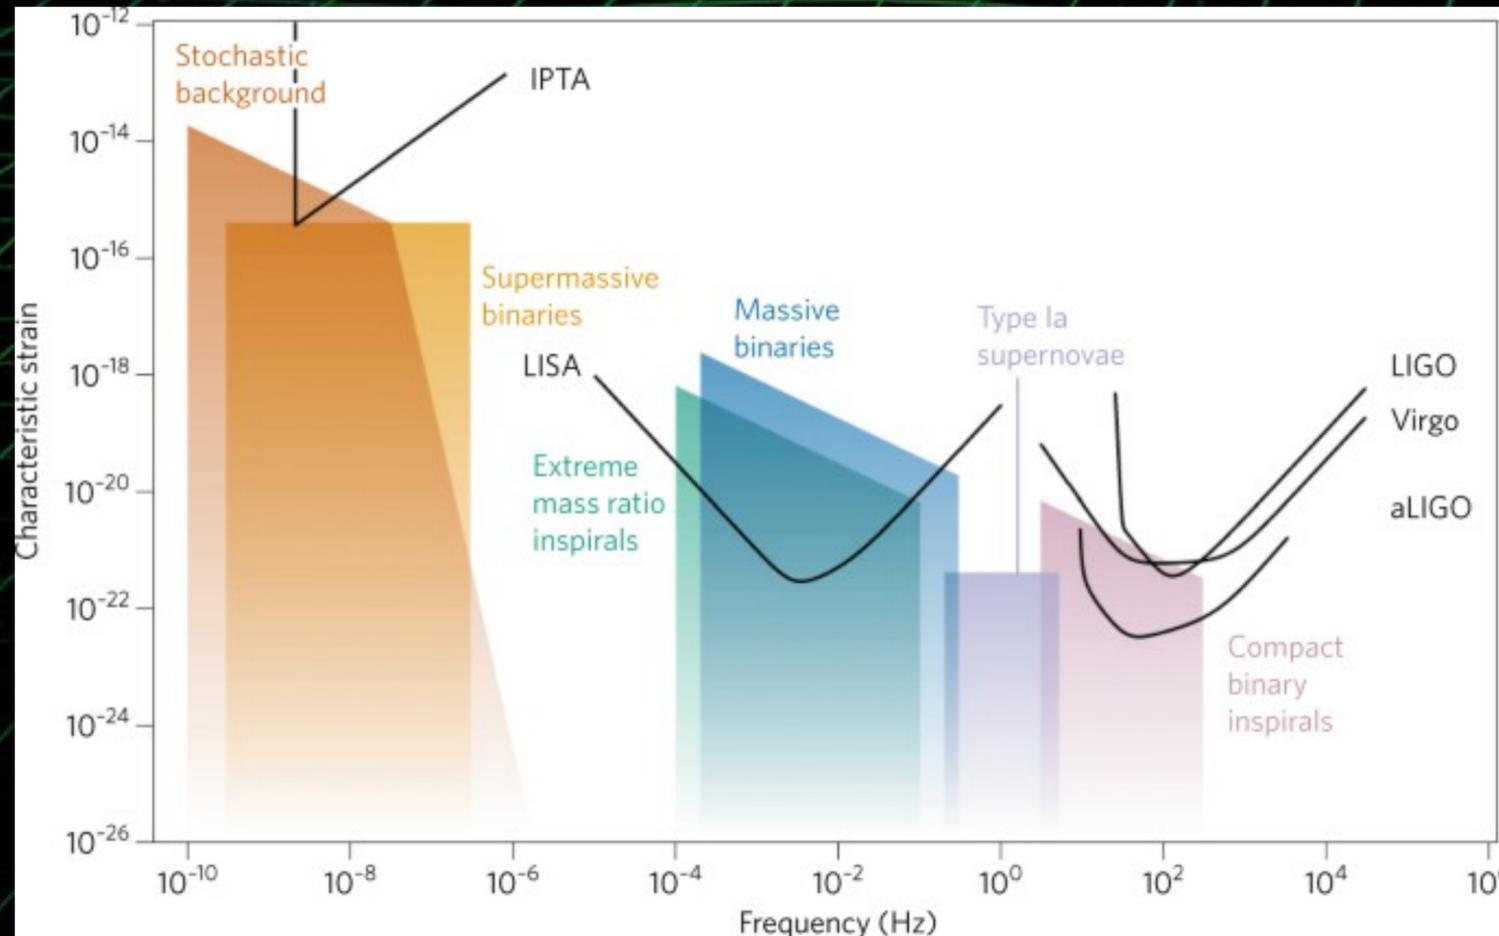

- The best pulsars keep time with an accuracy of 1 millionth of a second over 30 years (comparable to best atomic clocks)
- PSR J1012+5307: 15 years of obs with EPTA:
 $P = 0.005255749014115410 \pm 0.00000000000000000015 \text{ s}$ [Lazaridis et al. 2009]
→ 90 billion rotations since discovery, and not lost a single count!

Credit: Steve Taylor (2025)

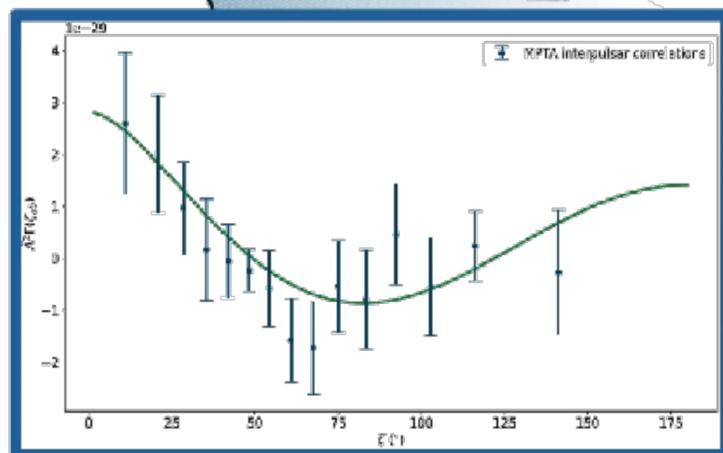

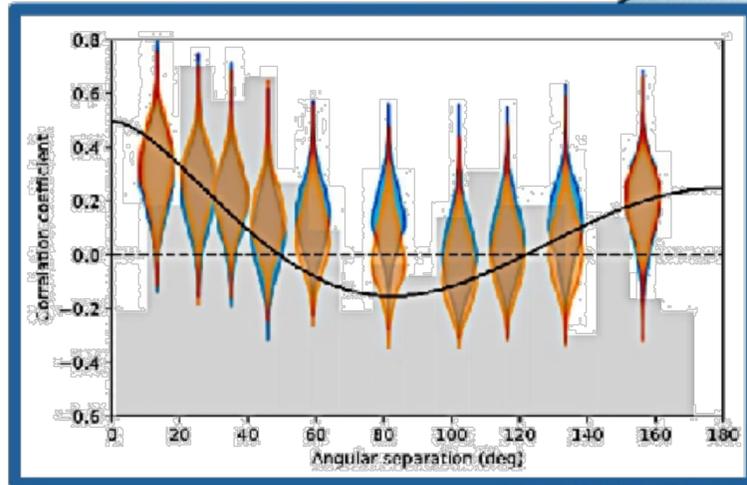

Agazie et al 2023 ApJL 951 L8

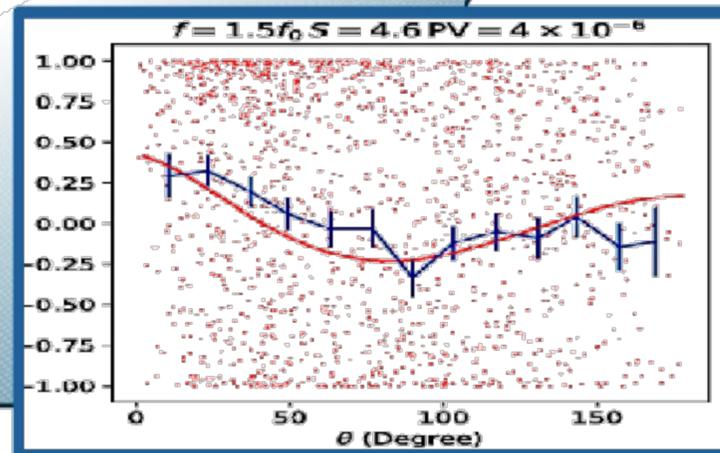

Reardon et al 2023 ApJL 951 L6

Antoniadis et al 2023 A&A 678, A50

Miles et al 2025 MNRAS 536 2

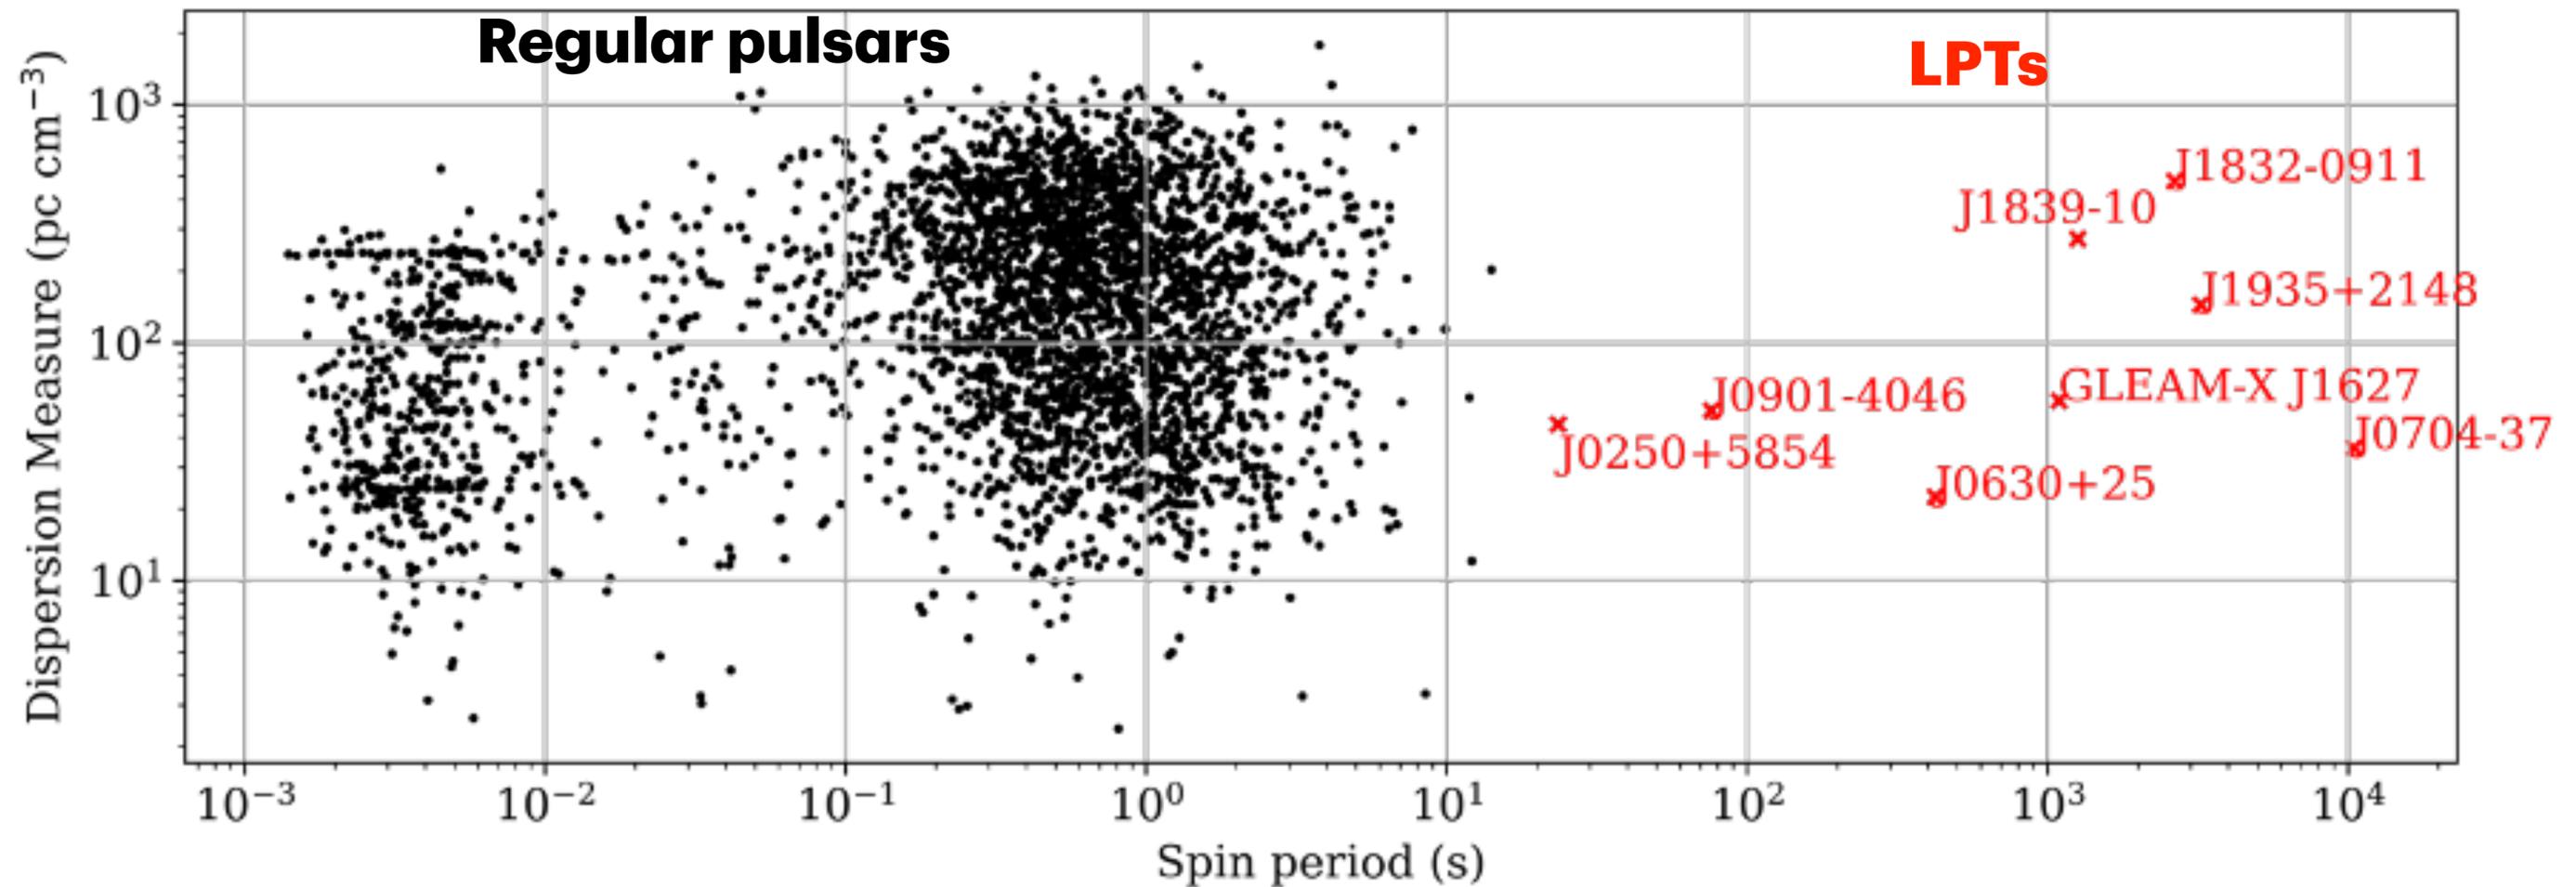

Xu et al 2023 RAA 23 075024

- Strong positive correlation when pulsars are close together
- Correlation decreases as separation increases
- Slightly negative near $\sim 90^\circ$
- Rises again slightly toward 180°
- GW distort ST in a quadrupolar pattern \rightarrow asymmetric shape

What else are new?

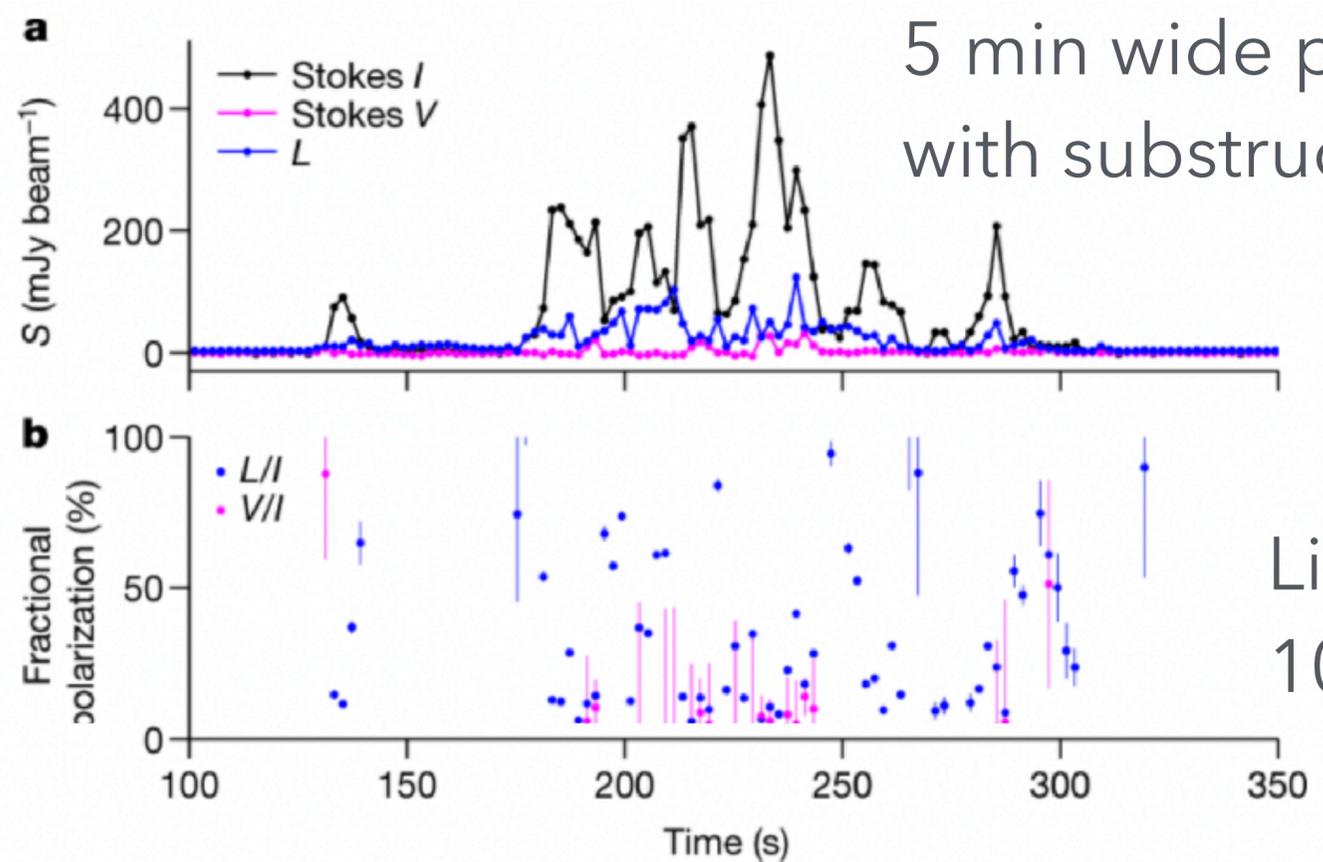

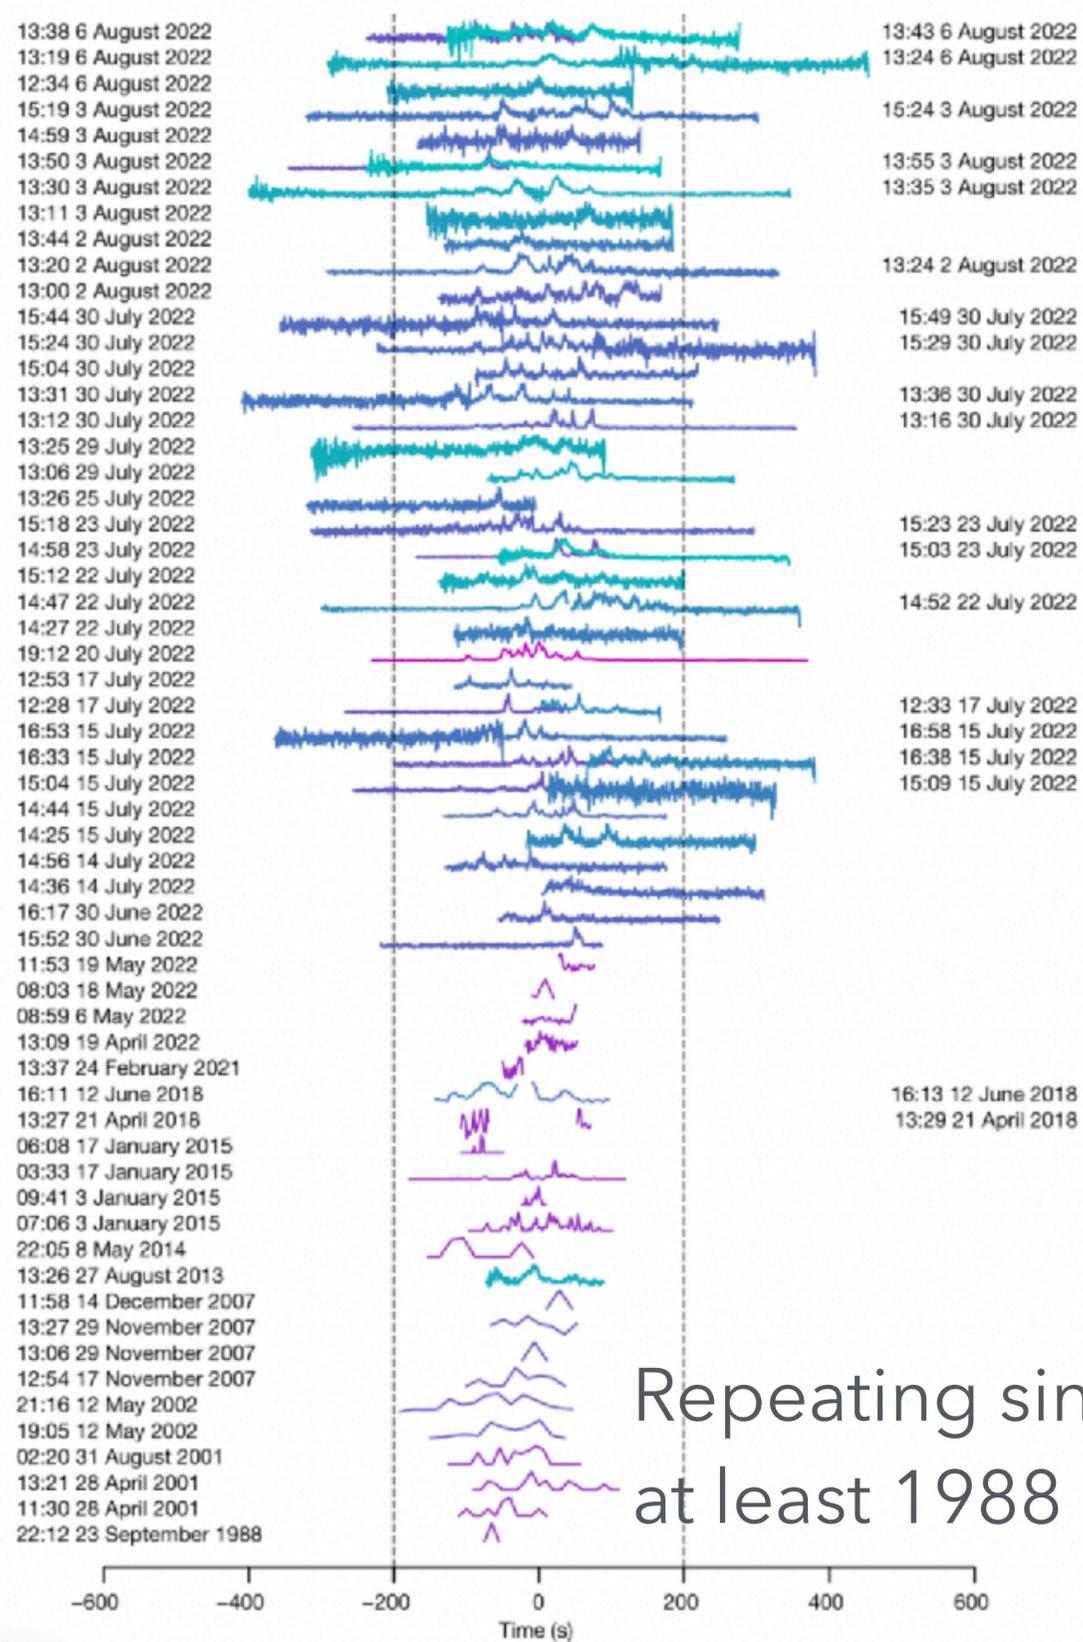

Long period transients

- LPTs: Periods > 10 s, slowest is ~ 6 hours
- First noticed in around 2022 (N. Hurley-Walker+2022)
- Rotational-powered pulsar spins down \rightarrow **electric potential** no longer accelerates enough charged particles to create **electron-positron pairs** \rightarrow Death lines

GPM J1839-10

Hurley-Walker et al. 2023

5 min wide pulses with substructure

Linear pol: 10%–100%

- Strict periodicity ($P \sim 22\text{min}$) + long-term stability
- Defies what we thought was physically possible for pulsars or magnetars
- Twisted magnetosphere — magnetically powered, ultra-slow pulsar?

Current Open Questions

- What is the exact radio emission mechanism?
- Why do pulsars **null** or switch modes?
- What determines the **death line**? (c.f. what are LPTs?)
- How are **fast radio bursts** related to neutron stars? (See next class)
- What can PTAs tell us about the **gravitational-wave background**?

Entretiens 2026 sur les pulsars et les étoiles à neutrons

June 1-2, 2026, at the APC, Paris

- provide a regular platform for the French pulsar community to meet, exchange ideas, and collectively advance the study of pulsars, neutron stars, and FRBs.
- not a traditional conference with strictly timed presentations, but rather a series of working sessions designed to encourage discussion (advances, challenges)
- participation of doctoral students is encouraged
- Registration is free
