UNIONS

cosmological results with 2D weak lensing

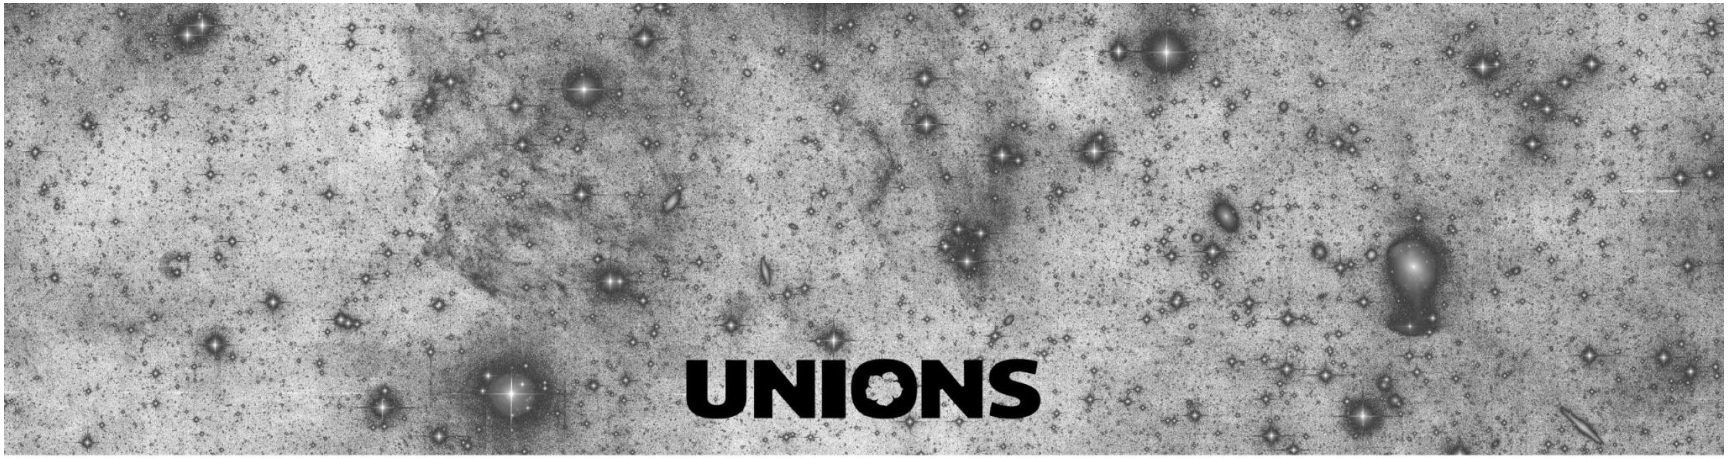
Martin Kilbinger
on behalf of the UNIONS CosmoStat Weak Lensing Team

Deep CosmoStat days, Feb 12, 2026

Outline of the talk

- The UNIONS survey
- Weak lensing with UNIONS
- First shear cosmology with UNIONS:
  - 2-point correlation functions
  - Image simulations & calibration
  - Systematics: PSF leakage & B-modes
  - Photometric redshift estimation & blinding
  - Inference & covariance
  - Cosmological constraints

UNIONS: A combination of 3 Hawai'ian telescopes

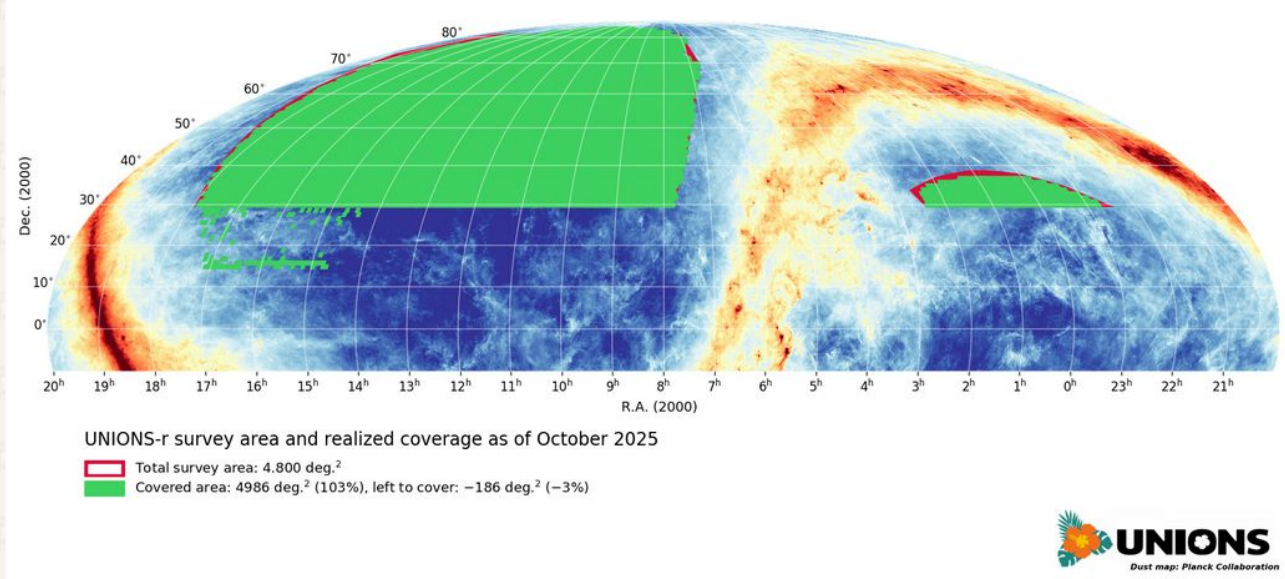


UNIONS: Ultra-violet Near-Infrared Optical Northern Survey

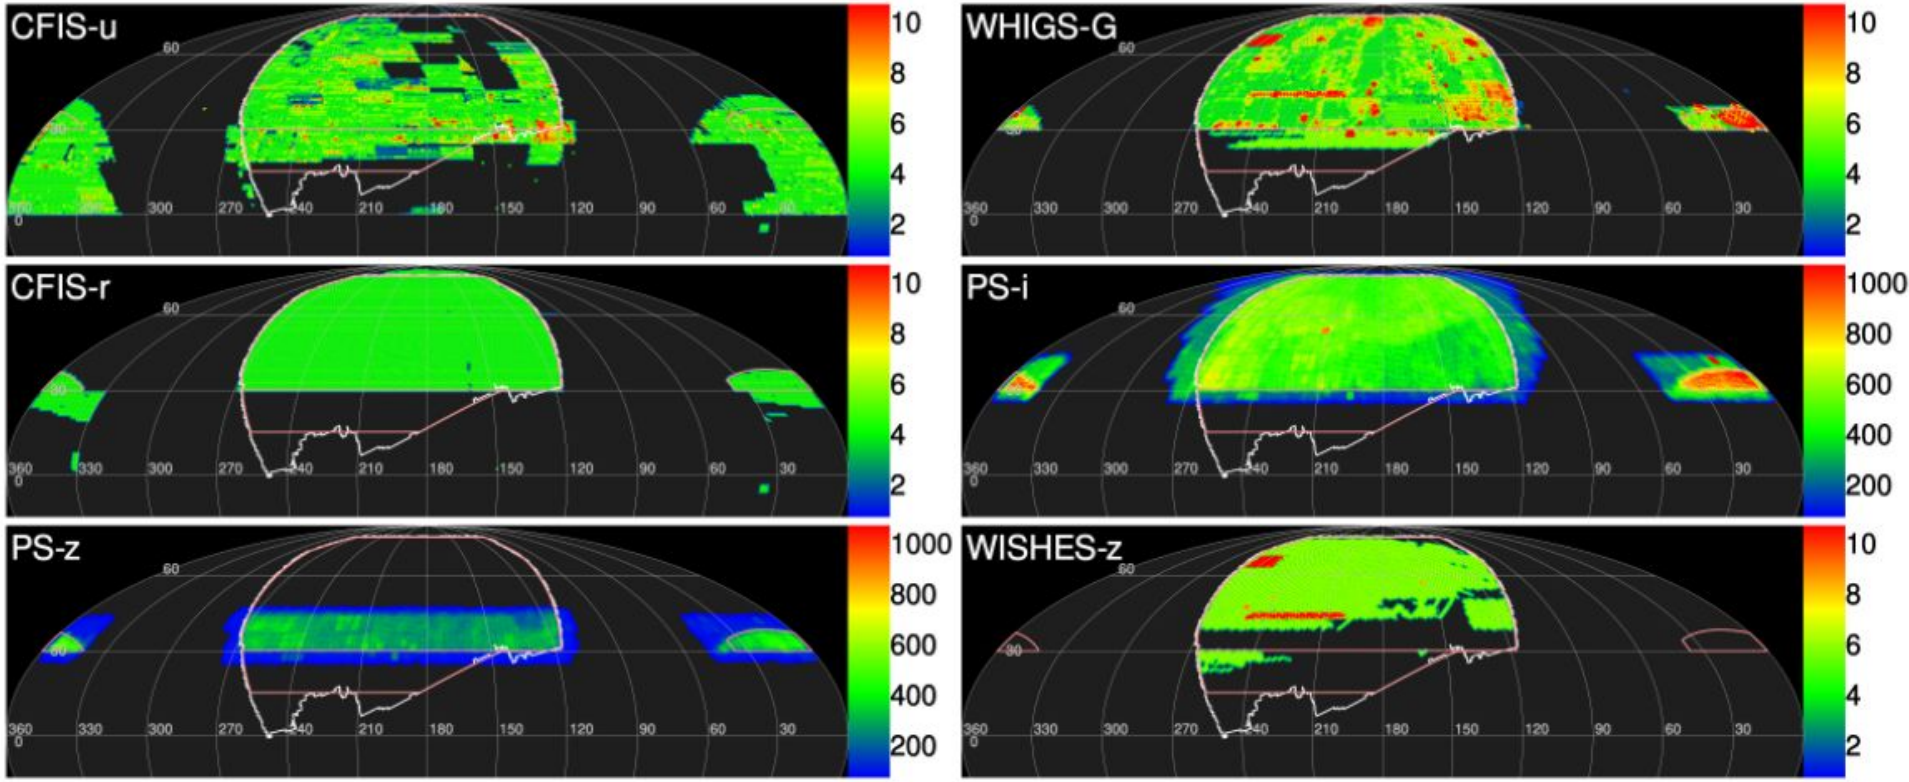
Goal: 6,200 deg^2 in 5 bands;
u, *r* (CFIS: Canada-France Imaging Survey)
i, *z* (Pan-STARRS)
g, *z* (HSC).

P.I.: Jean-Charles Cuillandre (CEA Paris-Saclay) & Alain McConnachie (Victoria/Canada)

- **Optical bands for Euclid for photometric redshifts**
- **Weak lensing**
- Milky Way dynamics
- Large-scale structure
- Galaxy evolution



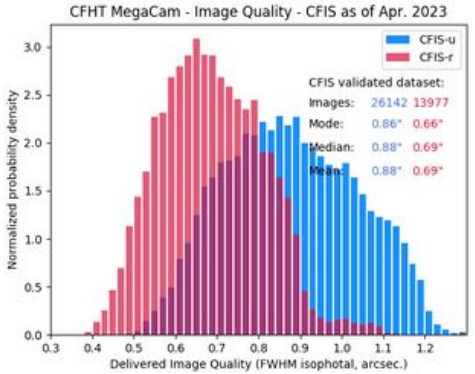
UNIONS multi-band data sky coverage

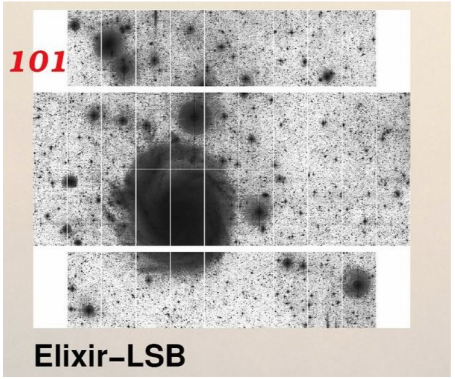


UNIONS image quality

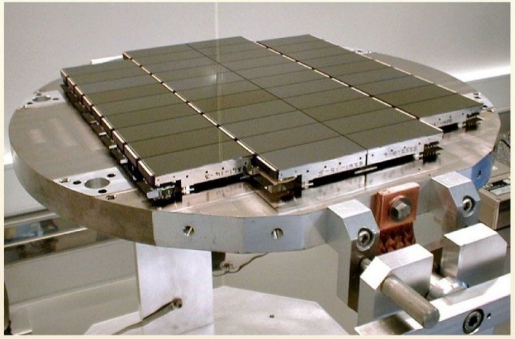
Best wide-field imager on CFHT ever.

Improvements (2011 - 2014)

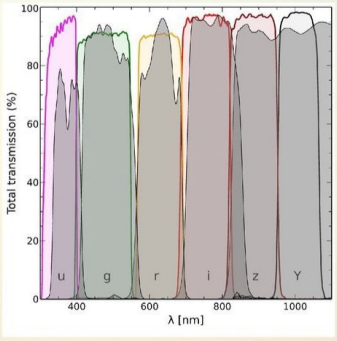




Dome venting



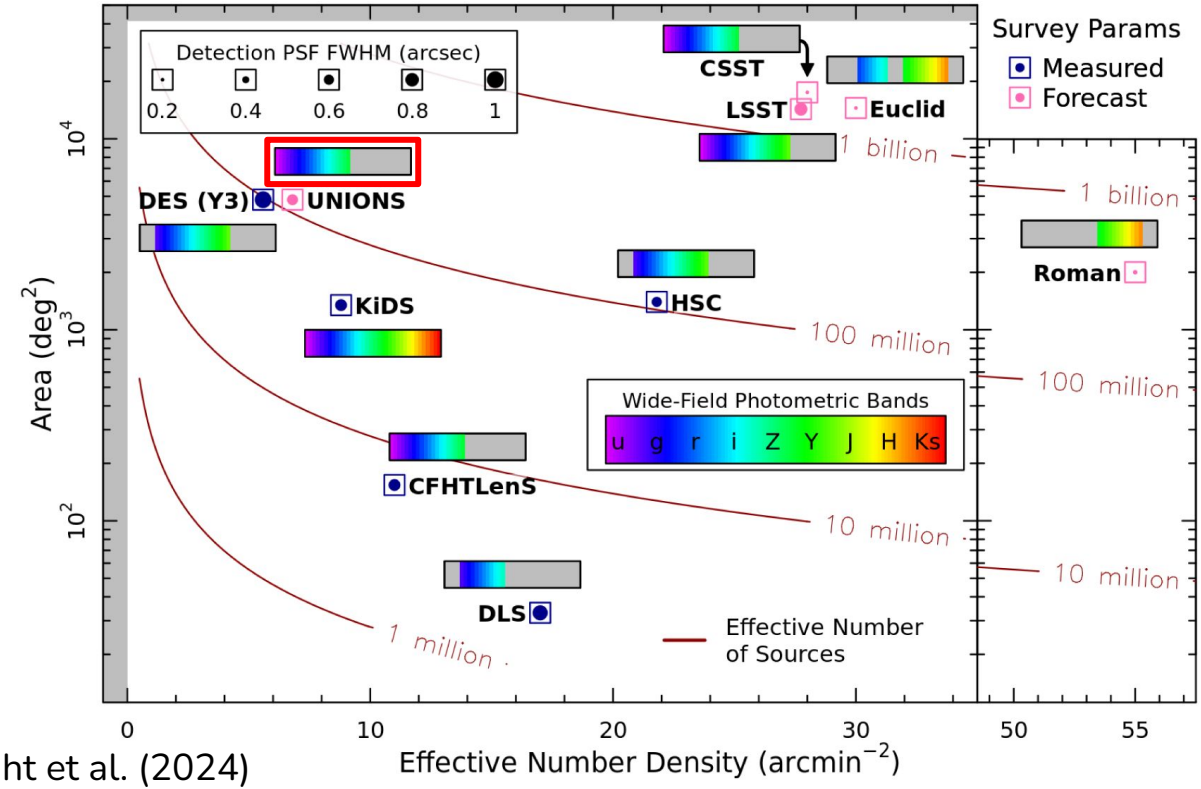
40 CCDs + Fast readout



New "square" filters

UNIONS in the broader survey landscape

Final UNIONS will be a “Stage 3.5” survey—roughly equivalent in depth & area to LSST Y1.



Wright et al. (2024)

ShapePipe & the UNIONS shape catalog

https://github.com/cosmostat/shapepipe

Farrens et al., 2022, A&A, 664, 141

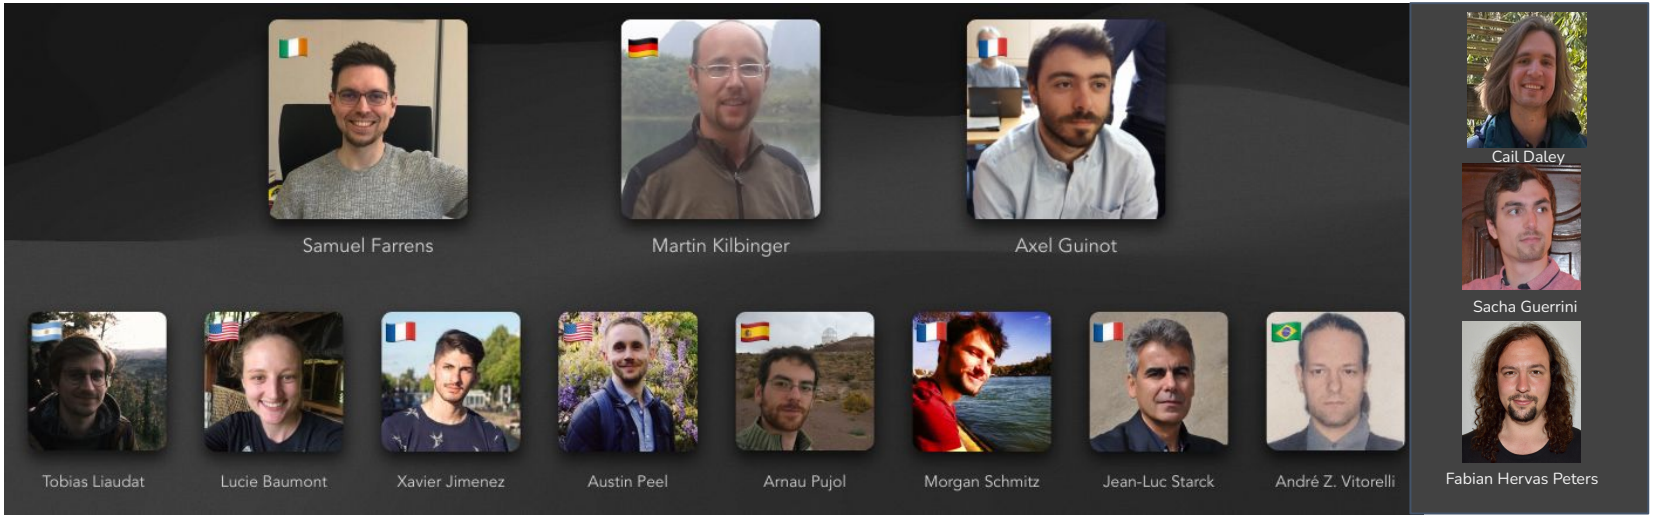
ShapePipe

CI passing | pages-build-deployment passing | python 3.9 | release v1.0.1

ShapePipe is a galaxy shape measurement pipeline developed within the CosmoStat lab at CEA Paris-Saclay.

See the documentation for details on how to install and run ShapePipe.

https://github.com/cosmostat/sp_validation/ for post-processing



ShapePipe philosophy

Goals

- Modular
- Easy
- Fast (enough)
- Robust

Code installation

- Conda
- Docker [allows for cloud computing]
- CD/CI

Three components

Pipeline

- Arguments & config
- I/O
- Job handling (MPI, SMP)
- Errors & logging

Modules

- WL data processing
- Book-keeping
- Post-processing

Utilities

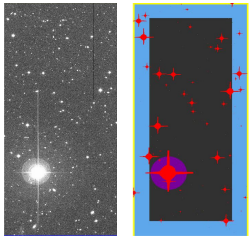
- Scripts
- Tools
- Survey-specific content

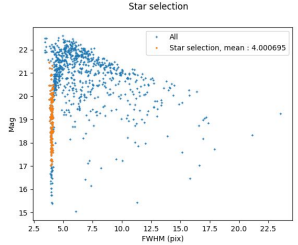
Can process 10k+ images, create catalogues with ~ 500 million objects, 150 Tb.

ShapePipe WL image processing

github/shapepipe
Farrens et al., 2022, A&A, 664, 141

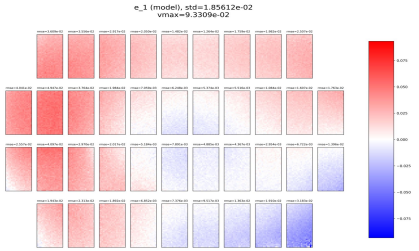
Input images are pre-processed (calibrated for astrometry and photometry)





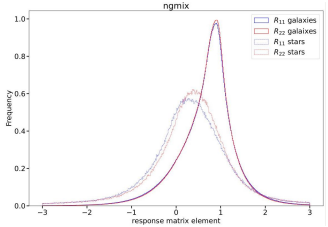
Main processing

- Mask
- Detect objects
- Star candidates on single exposures
- Galaxy candidates on stacks
- Select stars
- Create PSF model (PSFEx, Bertin et al. 2011; MCCD, Liaudat et al. 2021)
- Interpolate PSF model to galaxy positions
- Validate PSF model
- Measure galaxy shapes including calibration information [ngmix + metacalibration]



Post-processing

- Galaxy selection
- Apply calibration
- Systematic checks and validation



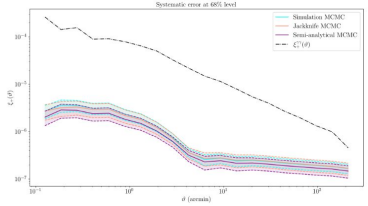


Image simulations & shear calibration

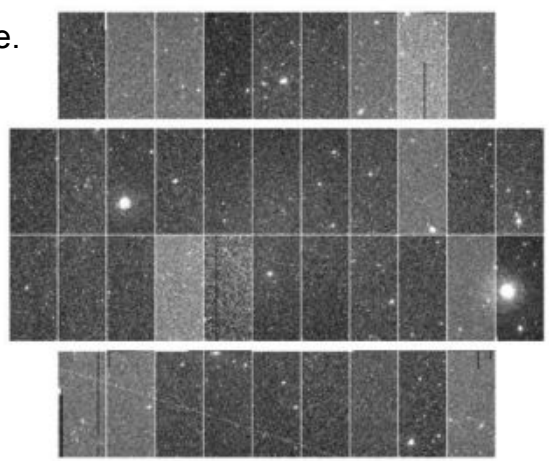
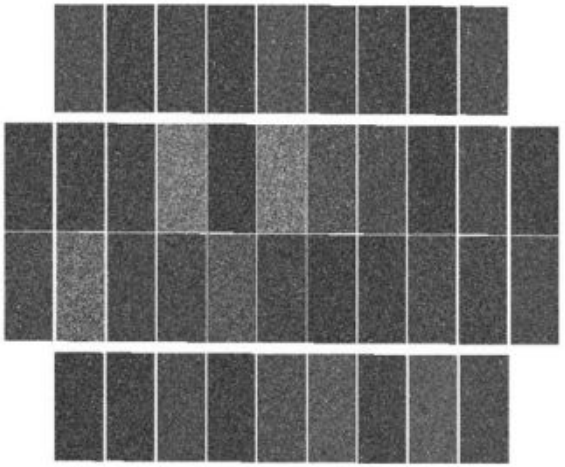
Simulated and real CFHT exposure.





Simulations:

- Realistic galaxy morphologies (Sérsic profiles matched to COSMOS
- Matching survey properties: camera geometry, dither pattern, noise
- Matching observed galaxy distribution: ellipticity, size, SNR, PSF, …
- 80 deg^2 for pipeline validation and calibration

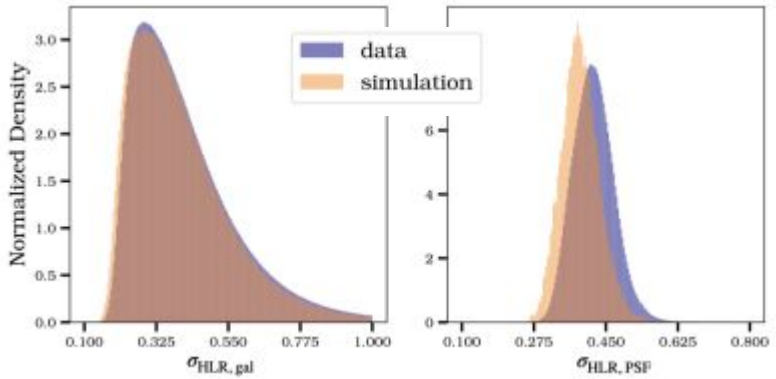


Image simulations & shear calibration

Shape/shear measurement: metacalibration = **self-calibration** using data.

Residual shear bias mainly from blends, expected 1-2%. Calibrated with **image simulations.** Final value TBD.

UNIONS vs. DES:

- Seeing 0.69” vs. 0.95”, less sensitive to blends:
  - **2✕ smaller** amplitude
  - At 2✕ smaller distance between galaxies

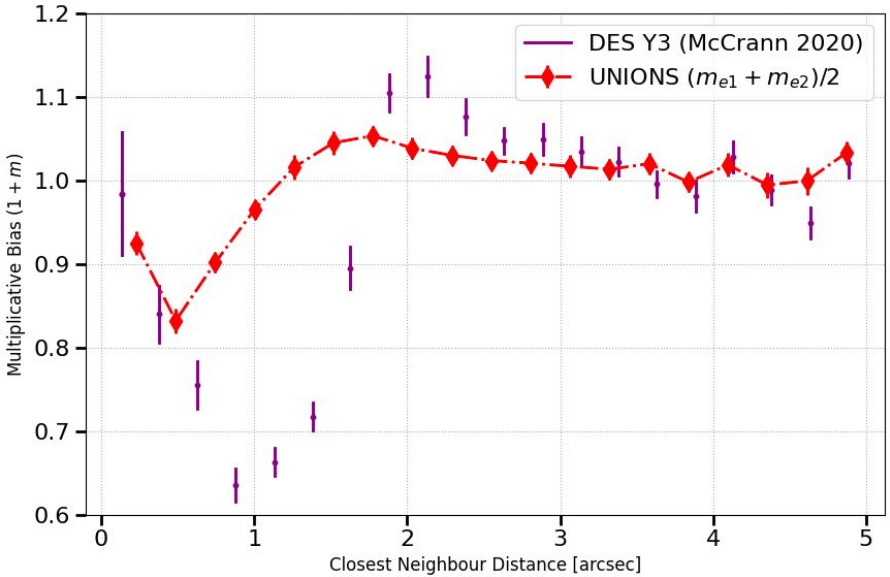

Image simulations & shear calibration

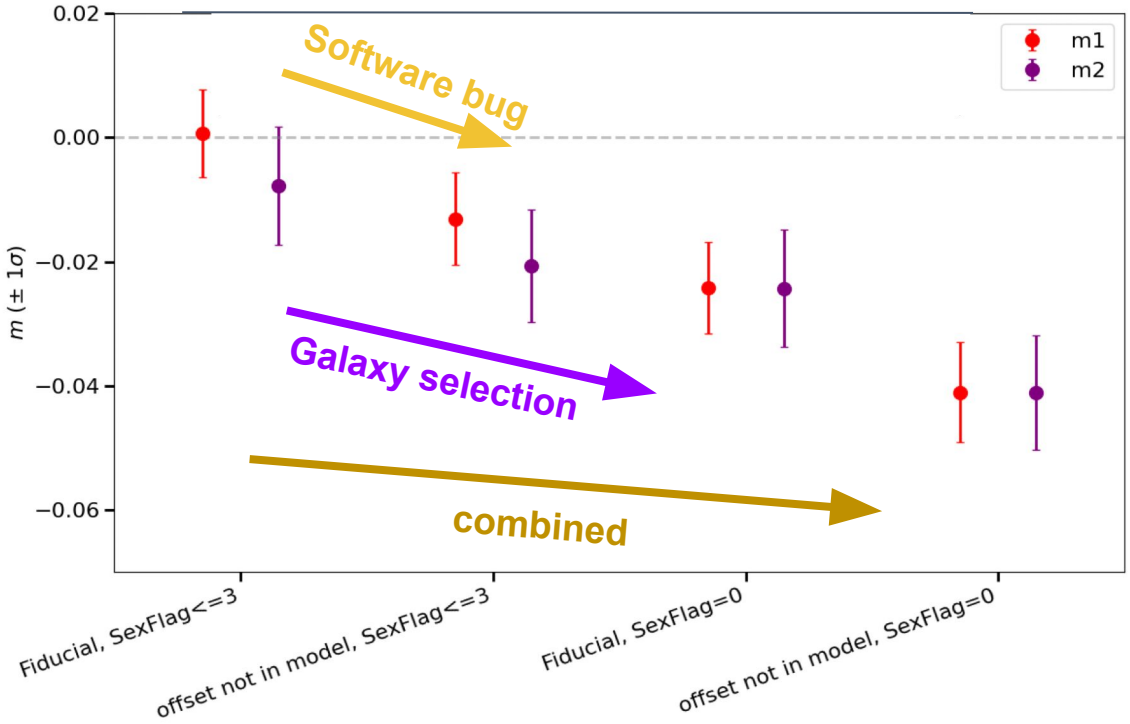
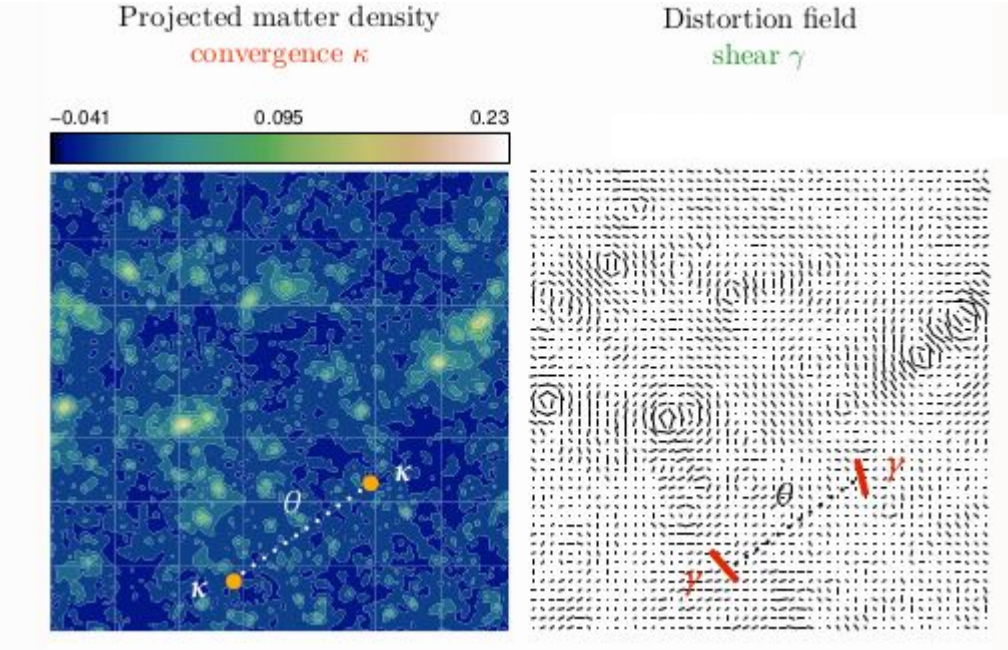
Additional residual shear bias *m*.

Simulations quantify *m* due to

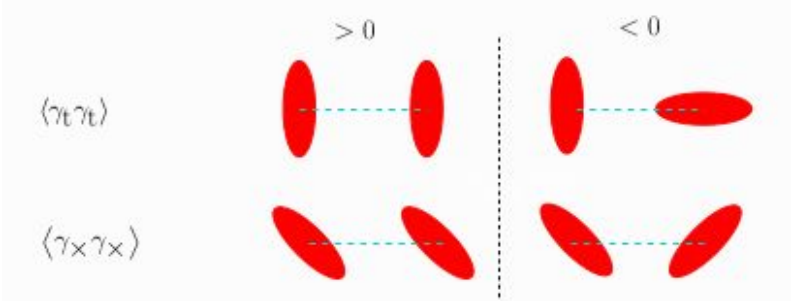
- **Software bug**
  (pixel vs. arcsec units)
- **Galaxy selection**
  (removing objects as blended is correlated with ellipticity and shear)



2-point correlation functions



2-point shear correlation function
↔variance of convergence σ^2_κ
↔ κ power spectrum
= projection(δ power spectrum)



Linear combinations

$$\xi_+(\vartheta) = \langle\gamma_t\gamma_t\rangle(\vartheta) + \langle\gamma_\times\gamma_\times\rangle(\vartheta)$$
$$\xi_-(\vartheta) = \langle\gamma_t\gamma_t\rangle(\vartheta) - \langle\gamma_\times\gamma_\times\rangle(\vartheta)$$

First shear cosmology with UNIONS

- Traditional cosmic shear analysis à la KiDS, DES, HSC.
- 2D: single redshift bin since more time is required to estimate & validate tomographic redshifts.
- Blinded analysis; blinding performed on the redshift distribution.
- 2-point correlation function (2PCF) used as data vector for cosmological inference.

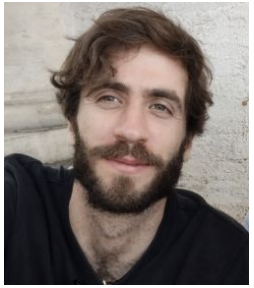
The 2D cosmic shear team

Core members in alphabetical order (many others have contributed as well):

Cail Daley
(B-mode systematics)

Lisa Goh
(inference / covariance)

Sacha Guerrini
(inference / PSF systematics)

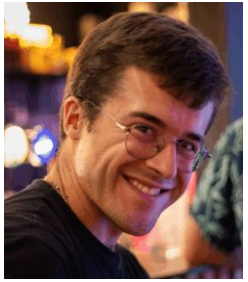


Calum Murray
(validation, IA)

Fabian Hervas-Peters
(image simulations)

Martin Kilbinger
(shape catalog)

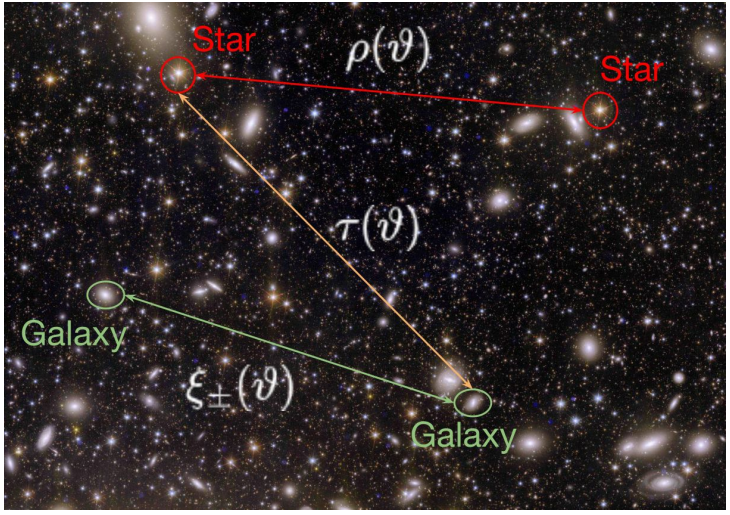
Anna Wittje
(redshift estimation)

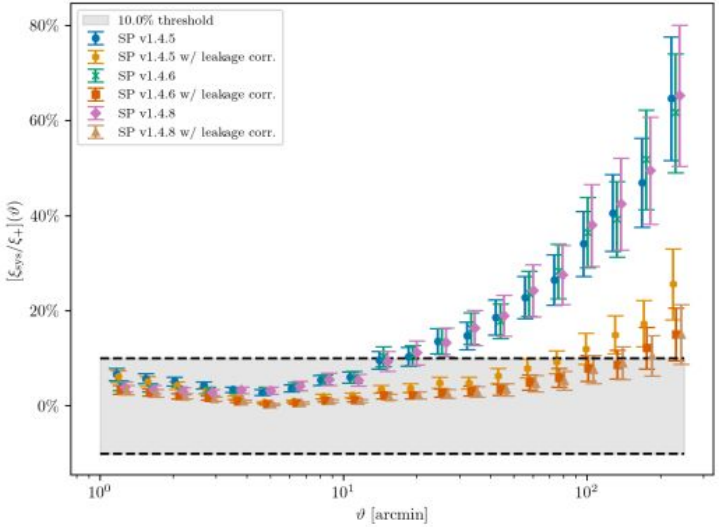


Antonin Corinaldi
(intrinsic alignment)

PSF Systematics

- Two modes:
  - PSF leakage: PSF imprint in galaxy shapes.
    UNIONS: 1-2% leakage; corrected on galaxy basis.
  - PSF modelling errors: residuals can mimic shear correlations.
- Use star-galaxy correlations to quantify [Guerrini et al. 2025]



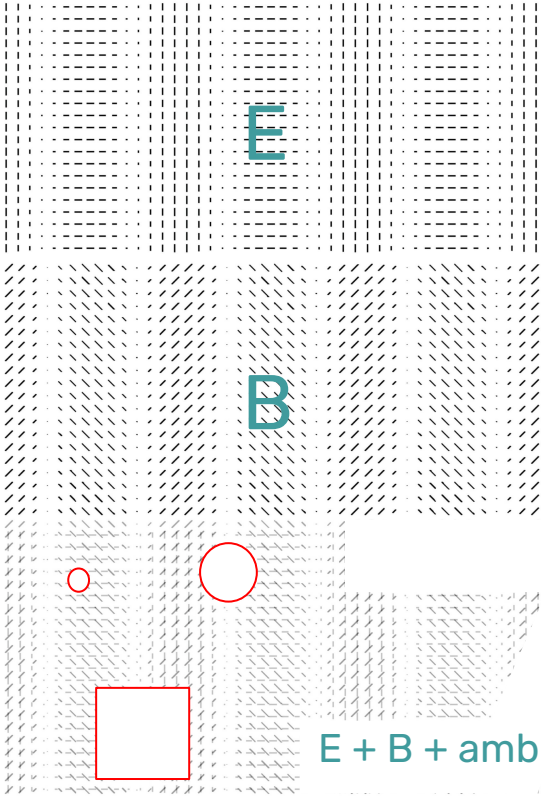


B-mode systematics

Spin-2 shear fields can be decomposed into **E-modes** containing the vast majority of lensing information and **B-modes** which are a probe of systematics at UNIONS noise levels.

In the presence of masking, some **ambiguous** modes cannot be cleanly attributed to E or B, although recent **purified** estimators can separate out these modes.

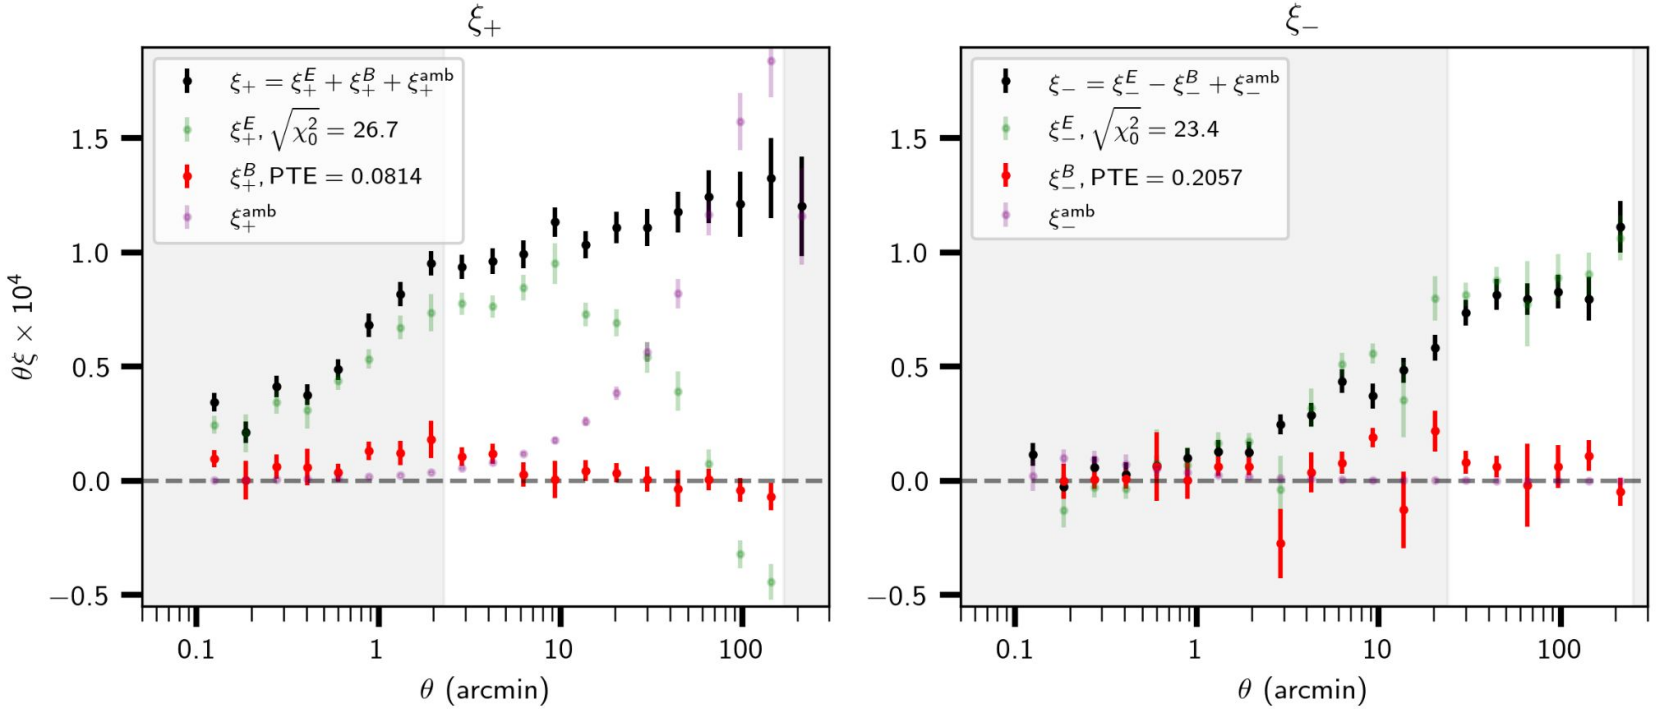
We use three B-mode approaches: pure correlation functions, COSEBIS, and bandpowers.



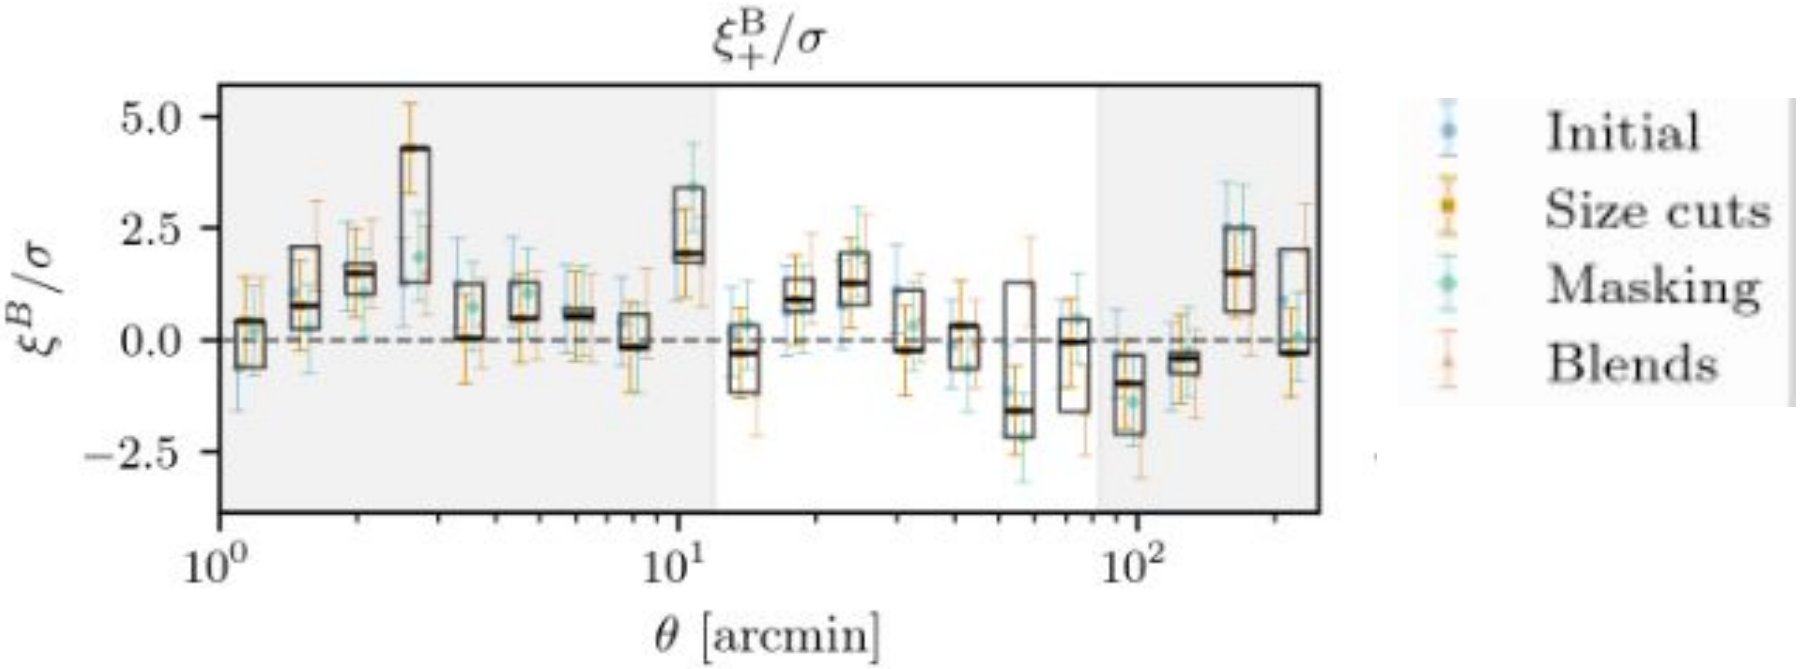
BICEP2 Collaboration

Pure B-mode correlation functions

B-modes on small scales (~4’ in ξ+ and ~30’ in ξ-); large scales are ok.



Pure B-mode correlation functions

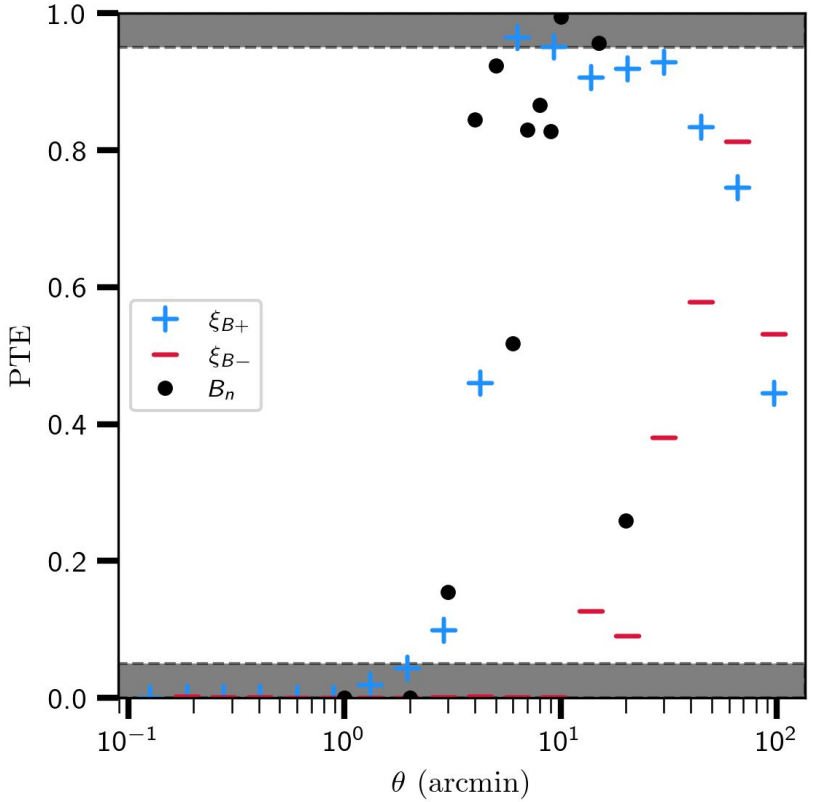


Testing masking and galaxy selections.

B-mode scale cuts

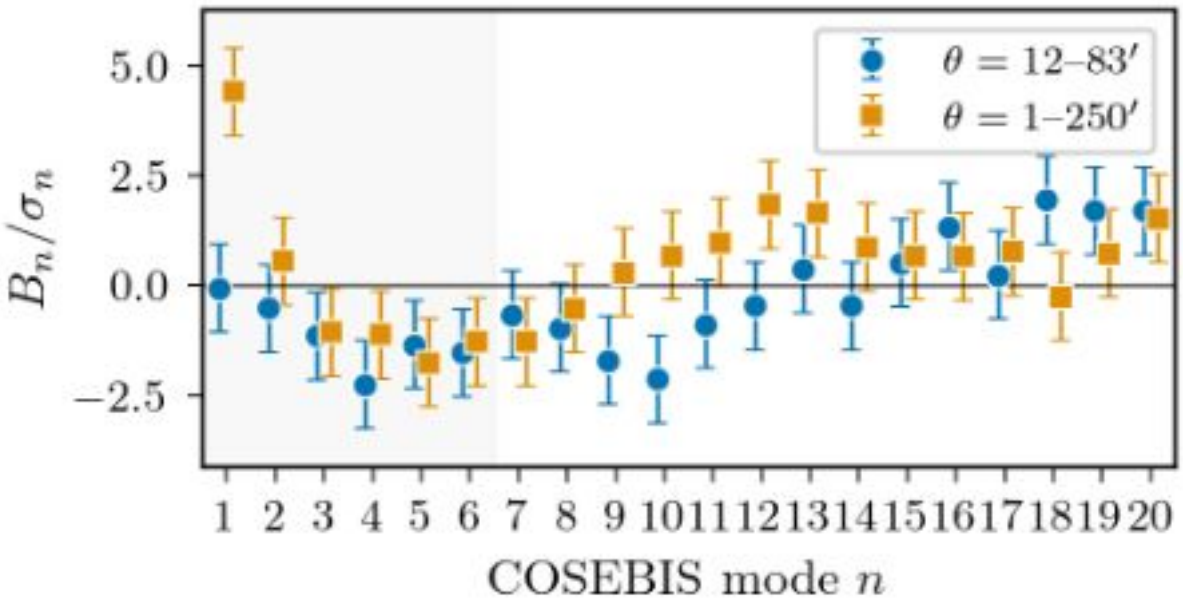
Pure-B correlation functions and COSEBIS tell a similar story:

- ξ+ PTE is acceptable above θ~3-4
- B□ (dominated by ξ+) PTE is acceptable above θ~3-4
- ξ- (probing ≲10x smaller scales) PTE is acceptable above θ~20-30.



B-mode COSEBIs

- Complete Orthgonal Sets of E-/B-mode Integrals [Schneider, Eifler & Krause 2010].
- Transform shear correlation function into discrete, pure E- and B-modes.
- First few modes have most SNR



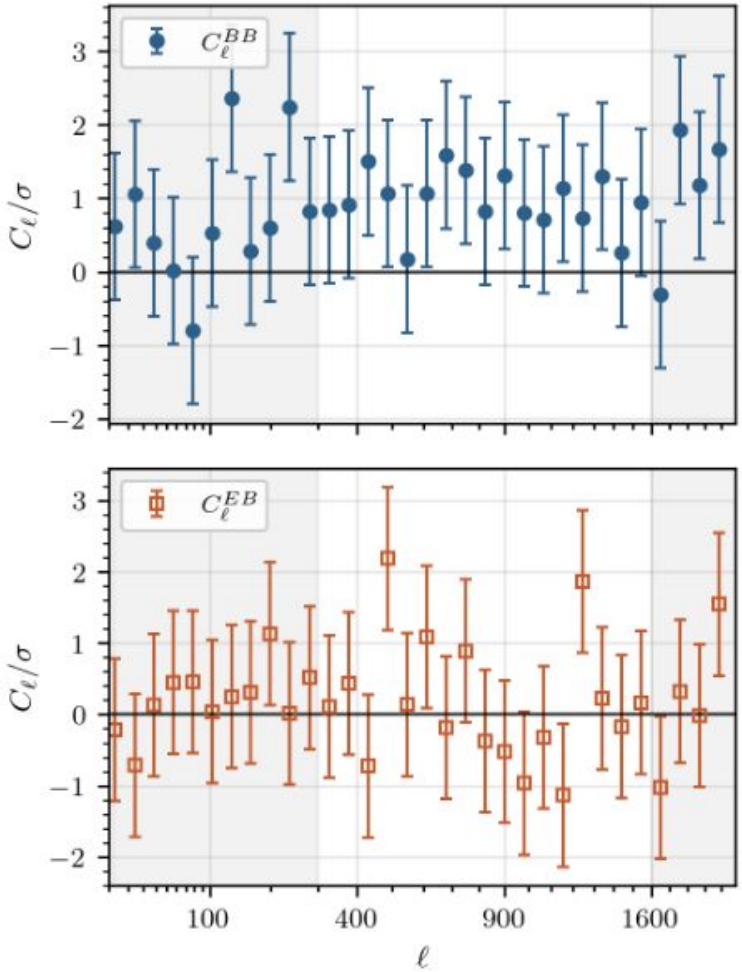
ℓ

B-mode band powers

Harmonic-space band power spectra.

- New direct catalogue-based estimation [Wolz et al. 2025], implemented in NaMaster
- Accounts for noise and mask mixing matrix, estimates covariance
- B-mode passes null test with l_{min}=300

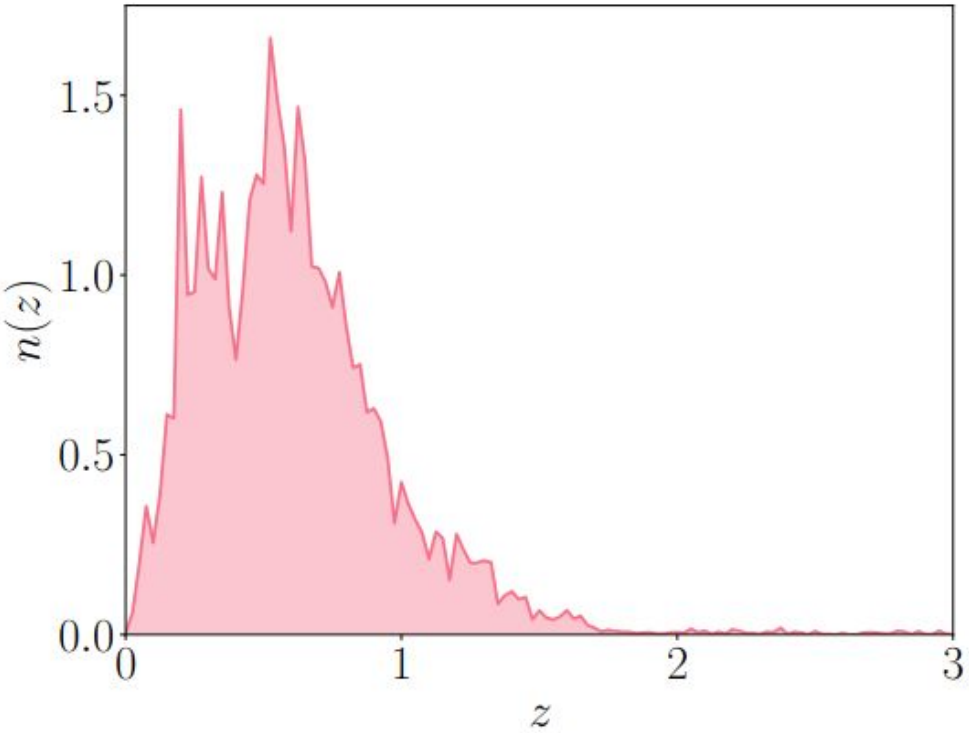
Conclusion: consistent scale cuts in configuration space (12’ - 83’) and harmonic space (300 - 1200).



Redshift Distributions

Redshift distribution estimated using self-organizing maps (SOMs).

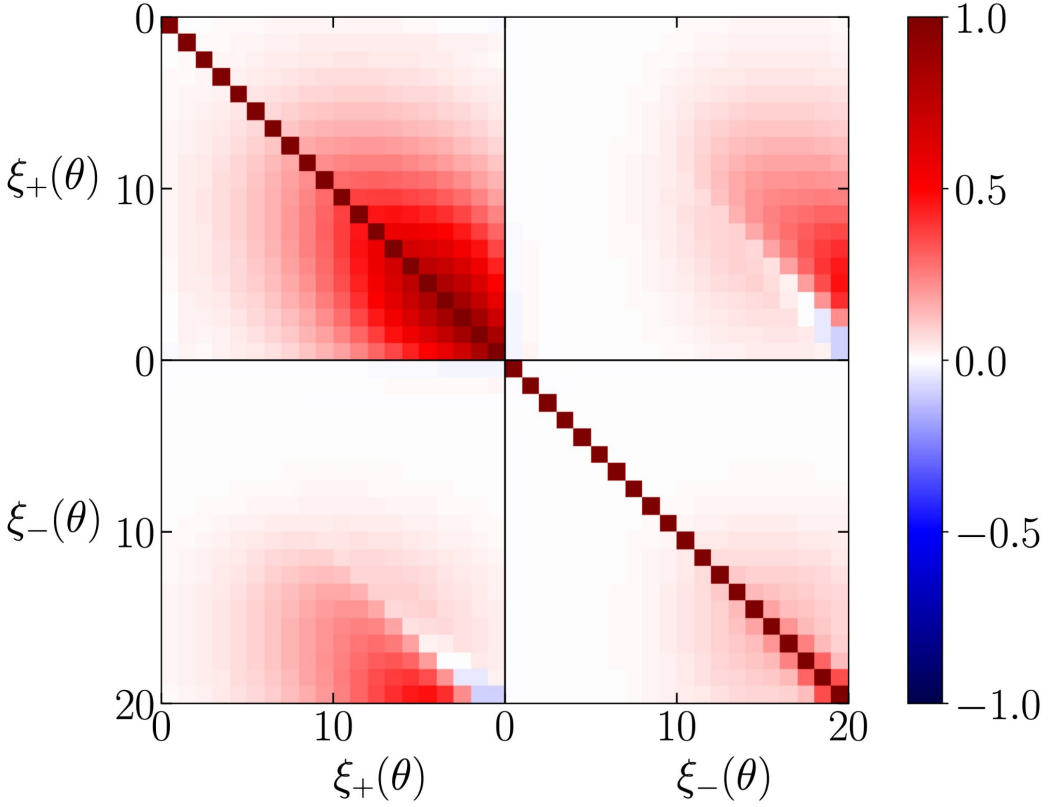
Three blinded redshift distributions produced—allows us to run the full inference pipeline on the data without risking confirmation bias.



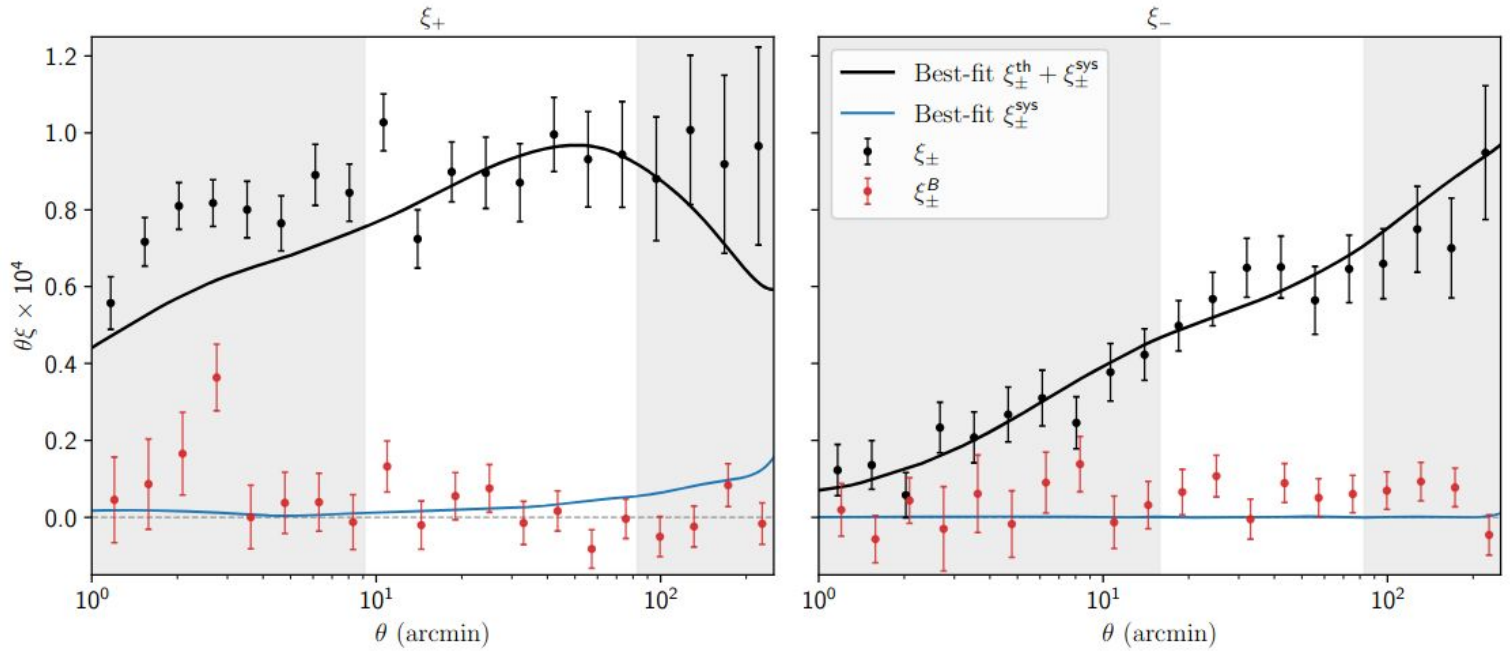
Covariance & Inference

Covariance estimated with CosmoCov and validated against data-driven jacknife.

Other parameters marginalized over in inference: intrinsic alignment [Hervas Peters 2024 direct measurement], multiplicative bias, PSF systematics, n(z) bias.

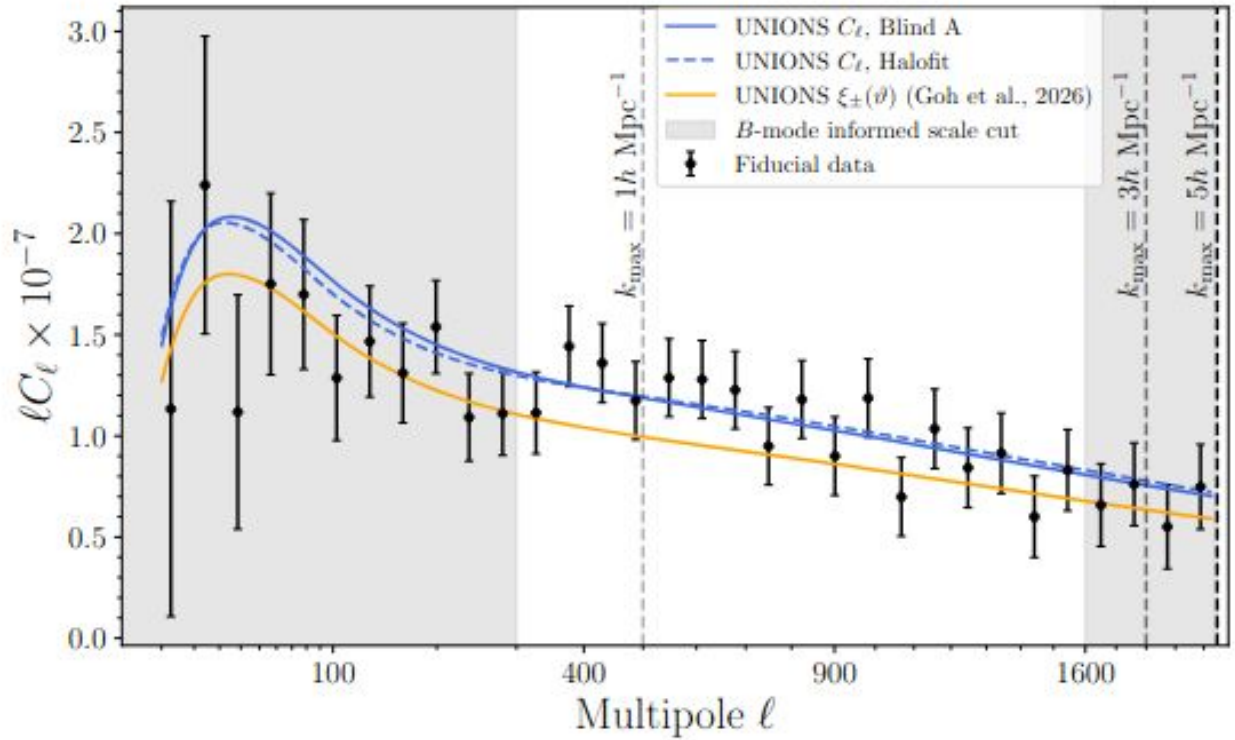


Current Best-fit Theory & Systematics



Cutting two 5’ < θ < 10’ data points in ξ+ improves χ² by 13..

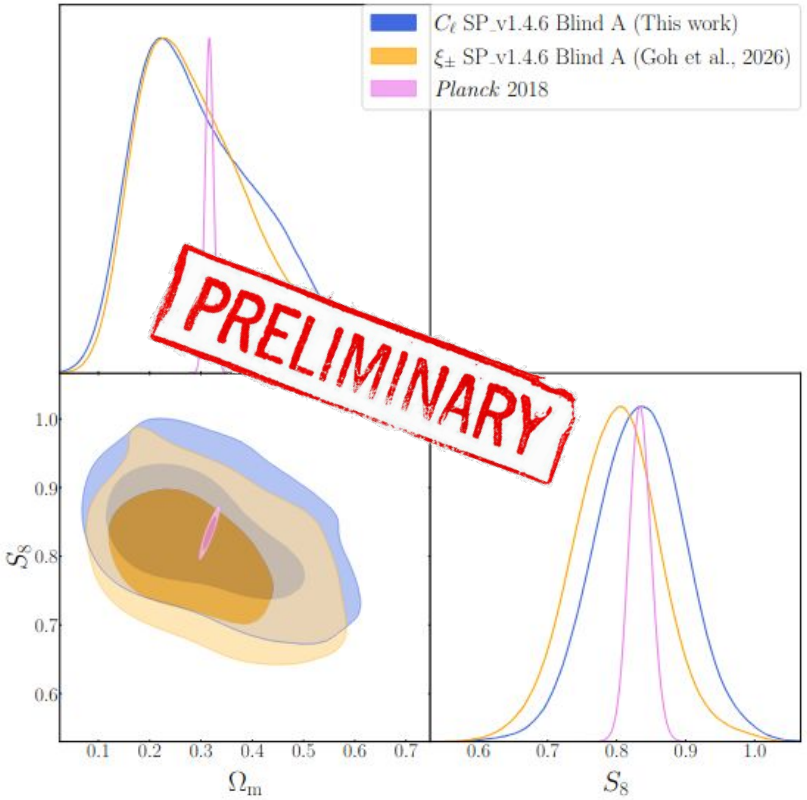
Best fit in harmonic space



Blinded Cosmological Contours

Constraints on S_8: ±0.06

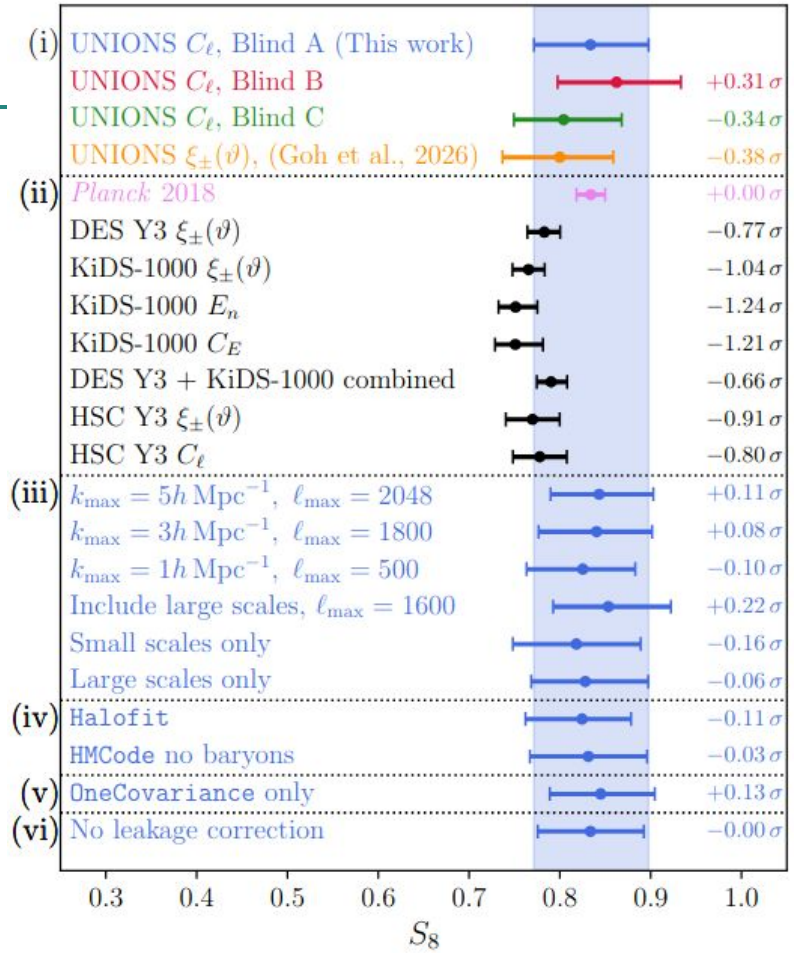
- ~0.015 comes from conservative θ > 10’ scale cut
- Non-tomographic analysis significantly reduces constraining power as well.
- Shift between configuration and harmonic space at 1.5σ



Blinded constraints

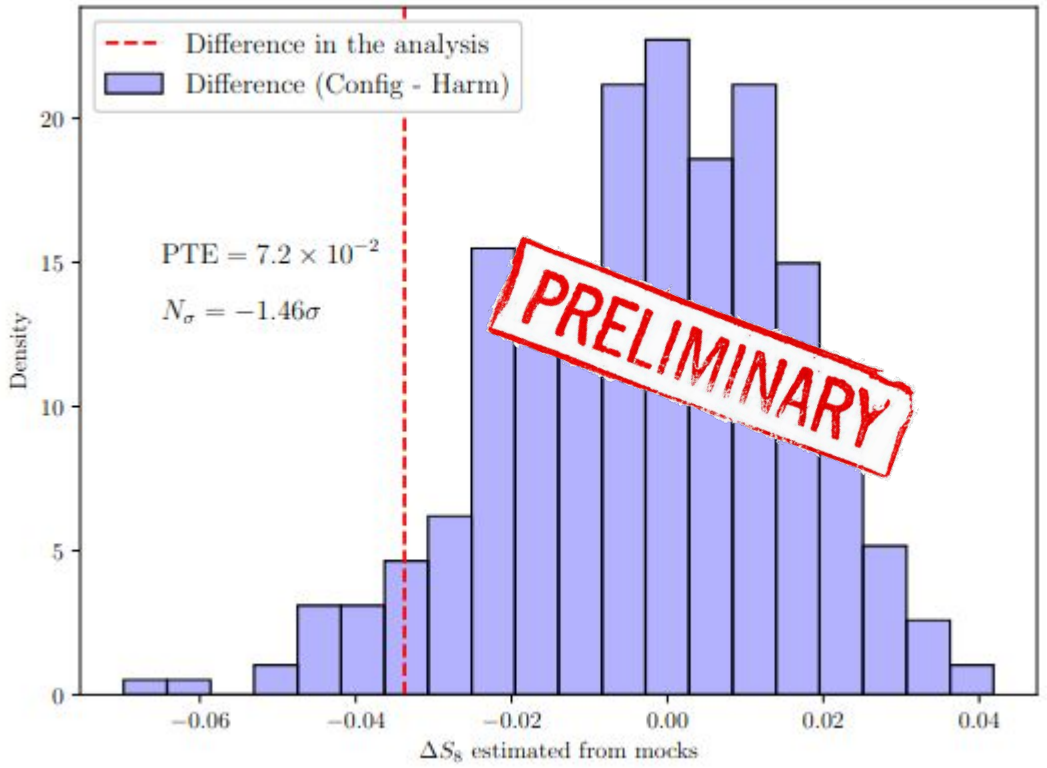
Constraints on S_8: ±0.06

- ~2-3x larger than best constraints from DES, HSC, & KiDS
- Somewhat larger; consistent with Planck and KiDS-Legacy
- Insensitive against further scale cuts, non-linear model, covariance.



Configuration vs. harmonic space

- Shift quantified with log-normal mocks.
- Skewed distribution?
- Similarly observed in KiDS.



Summary & Next Steps

- UNIONS is a unique dataset for weak lensing:
  - excellent image quality (Mauna Kea)
  - homogeneous survey depth (adaptive observing strategy).
  - Large area (> 6,000 deg2)
  - Very good photo-z's (*u*-band @ CFHT)
- Competitive in the Euclid and Rubin era, in particular for cross-correlations with SDSS and DESI: lensing by galaxies, groups, clusters, voids; 3x2pt.
- First UNIONS cosmic shear results are imminent!
  - Analysis is in its final stages, tracking down potential scale-dependent systematics before unblinding.
  - Error bar on S_8 forecasted to be ~0.06, and may improve if we can reduce systematics on small scales.
- Up next: simulation-based inference, tomographic analysis, and much more!

Intrinsic alignment at formation time	Murray et al. in prep.
Intrinsic alignment multipole measurements	Paviot et al. in prep.

PSF Systematics

Three quantities can be used to form six ρ-statistics and three τ-statistics:

- Ellipticity
  (model & galaxy)
- Ellipticity errors
  (model evaluated at star locations)
- Size errors
  (model evaluated at star locations)

$$\delta\mathbf{e}^{\mathrm{sys}}_{\mathrm{model}} = \alpha \underbrace{\mathbf{e}_{\mathrm{model}}}_{\text{Leakage}} + \beta \underbrace{(\mathbf{e}_* - \mathbf{e}_{\mathrm{model}})}_{\text{Ellipticity error}} + \eta \underbrace{\left(\mathbf{e}_* \frac{T_* - T_{\mathrm{model}}}{T_*}\right)}_{\text{Size error}}$$

$$\begin{pmatrix} \tau_{0,1} \\ \tau_{2,1} \\ \tau_{5,1} \\ \vdots \\ \tau_{0,n} \\ \tau_{2,n} \\ \tau_{5,n} \end{pmatrix} = \begin{pmatrix} \rho_{0,1} & \rho_{2,1} & \rho_{5,1} \\ \rho_{2,1} & \rho_{1,1} & \rho_{4,1} \\ \rho_{5,1} & \rho_{4,1} & \rho_{3,1} \\ & \ddots & \\ \rho_{0,n} & \rho_{2,n} & \rho_{5,n} \\ \rho_{2,n} & \rho_{1,n} & \rho_{4,n} \\ \rho_{5,n} & \rho_{4,n} & \rho_{3,n} \end{pmatrix} \begin{pmatrix} \alpha \\ \beta \\ \eta \end{pmatrix},$$

Solve system of linear equations to get leakage contribution to 2PCF:

$$\xi_{\mathrm{PSF,sys}}(\vartheta) = \alpha^2 \rho_0(\vartheta) + \beta^2 \rho_1(\vartheta) + \eta^2 \rho_3(\vartheta) + 2\alpha\beta \rho_2(\vartheta) + 2\alpha\eta \rho_5(\vartheta) + 2\beta\eta \rho_4(\vartheta)$$
