

Gravitational Waves:

The instrumental challenges of the detection

*Romain Gouaty
LAPP – Annecy
GraSPA summer school*

Table of Contents

- **Principles:**
 - Effect of GW on free-fall masses
 - Basic detection principle overview
- **Virgo optical configuration or how to measure 10^{-20} m**
 - Simple Michelson interferometer
 - How do we improve the detector sensitivity?
 - How to measure the GW strain $h(t)$ from this detector?
- **Noises limiting the ITF sensitivity: how to tackle them?**
- **Prospectives for interferometers and other detectors**

Reminder: effect of a GW on free fall masses

A gravitational wave (GW) modifies the distance between free-fall masses

Reminder: effect of a GW on free fall masses

A gravitational wave (GW) modifies the distance between free-fall masses

$$\delta x(t) = -\delta y(t) = \frac{1}{2} h(t) L_0$$

$h(t)$: amplitude of the GW (= strain)

Typical amplitude of a GW crossing the Earth:
 $h \sim 10^{-23}$
(h has no dimension/unit)

Case of a GW with polarisation + propagating along z

Reconstructed strain of GW150914

Terrestrial GW Interferometer: basic principle

- Measure a variation of distance between masses
 - Measure the light travel time to propagate over this distance
 - Laser interferometry is an appropriate technique
 - Comparative measurement
 - Suspended mirrors = free fall test masses

Terrestrial GW Interferometer: basic principle

Terrestrial GW Interferometer: basic principle

- Measure a variation of distance between masses
 - Measure the light travel time to propagate over this distance
 - Laser interferometry is an appropriate technique
 - Comparative measurement
 - Suspended mirrors = free fall test masses

- Michelson interferometer well suited:
 - Effect of a gravitational wave is in opposition between 2 perpendicular axes
 - **Light intensity of interfering beams is related to the difference of optical path length in the 2 arms**

Bandwidth: 10 Hz to few kHz

We need a big interferometer:

ΔL proportional to L

→ need several km arms!

Virgo/LIGO: more complicated interferometers

Suspended mirrors

→ Mirrors can be considered as free-falling in the ITF plane for frequencies larger than ~ 10 Hz

WARNING: STILL VERY SIMPLIFIED SCHEME!

Orders of magnitude

Typical amplitude of differential arm length variations when a GW crosses the Earth:

$$\begin{aligned} \delta \Delta L &= \delta l_x(t) - \delta l_y(t) \\ &= h(t) L_0 \end{aligned}$$

$$\begin{aligned} h &\sim 10^{-23} & L_0 &= 3 \text{ km} \\ \rightarrow \delta \Delta L &\sim 3 \times 10^{-20} \text{ m} \\ &\sim \frac{\text{size of a proton}}{100000} \end{aligned}$$

Km scale interferometers

Virgo

- Arm length = 3 km
- Cascina (near Pisa), Italy

LIGO Livingston

- Arm length = 4 km
- Louisiana

LIGO Hanford

- Arm length = 4 km
- Washington State

KAGRA

- Arm length = 3 km
- Underground
- Japan

The detector network

The benefits of the network

- A GW interferometer acts as a wide beam antenna
 - A single detector cannot localize the source
 - Need to compare the signals found in coincidence between several detectors (triangulation):

→ allow to point towards the source position in the sky
→ the telescope is obtained by a network of interferometers

- Looking for rare and transient signals: can be hidden in detector noise
 - requires observation in coincidence between at least 2 detectors
- Since 2007, Virgo and LIGO share their data and analyze them jointly
- Now building the International Gravitational-Wave Network with KAGRA and LIGO India

Multi-messenger astronomy

Astrophysical alerts

GCN (GRBs)

Swift, Fermi, INTEGRAL, ...

SNEWS (supernova)

IceCube, Super-K, SNO, LVD

Alerts in LIGO-Virgo control rooms

Specific analysis (on-line and later)

Online GW candidates (LIGO-Virgo)

+ checks by rapid response team
(operators on sites + remote scientists on shift)

Alerts for the observatories

Radio and optical telescopes

ROTSE, TAROT, SkyMapper, QUEST,
Pi of the Sky, Zadko, Liverpool Telescope, LOFAR

X-ray satellites

Swift/XRT

γ -ray telescopes

HESS, CTA

- Increase the significance of the events
- Better understand the physics of the sources

Table of Contents

- **Principles:**
 - Effect of GW on free-fall masses
 - Basic detection principle overview
- **Virgo optical configuration or how to measure 10^{-20} m**
 - Simple Michelson interferometer
 - How do we improve the detector sensitivity?
 - How to measure the GW strain $h(t)$ from this detector?
- **Noises limiting the ITF sensitivity: how to tackle them?**
- **Prospectives for interferometers and other detectors**

Electromagnetic waves

- Propagation of a perturbation of electric and magnetic fields
- Direction of propagation: along $\vec{k}$
- E and B are in phase, and with perpendicular directions
- E and B are perpendicular to the direction of propagation of the wave (transverse wave)
- Amplitude: amplitude of the E (or B) field,
- Two polarisations: defined by the direction of E (or B)

$$\vec{B} = \frac{\vec{k} \times \vec{E}}{c}$$

Description of plane waves

- Plane wave propagating along z , with speed c

$$A(z, t) = A_0 \cos(kz - \omega t + \epsilon) \quad (\text{since } \vec{k}\vec{r} = kz)$$

{	A_0	amplitude
	λ	wavelength (m)
	$k = \frac{2\pi}{\lambda}$	wave number (rad/m)
	$\omega = kc$	angular frequency (rad/s)

- Average power: $P \propto A_0^2$

- Complex form

$$U(z, t) = A_0 e^{j(kz - \omega t + \epsilon)}$$

$$= \underline{A_0} e^{j(kz + \epsilon)} \quad \text{with} \quad \underline{A_0} = A_0 e^{-j\omega t}$$

--> simpler algebraic calculations, for example $P \propto |U|^2 = UU^*$

--> real plane wave is the real part: $\Re(U(z, t)) = A(z, t)$

- Plane waves do not exist but they are a good approximation of many waves in localized region of space

How do we « observe » ΔL with a Michelson interferometer?

- Input wave $U_i(x, t) = \underline{\mathcal{A}_i} e^{j k x}$
 $= \underline{\mathcal{A}_i}$ on BS
- BS located at (0,0)
- Sensor located at (0, $-y_s$)
- Amplitude reflection and transmission coefficients: r and t

→ We are interested in the beam transmitted by the interferometer: it is the sum of the two beams (fields) that have propagated along each arm

Around the mirrors:

- Radius of curvature of the beam ~ 1400 m
- Size of the beam $\sim$ few cm

→ The beam can be approximated by plane waves

How do we « observe » ΔL with a Michelson interferometer?

- Input wave $U_i(x, t) = \underline{\mathcal{A}}_i e^{j k x}$
 $= \underline{\mathcal{A}}_i$ on BS
- Beam propagating along x-arm:

$$U_{tx} = \underline{\mathcal{A}}_i t_{BS} e^{j k l_x} \dots\dots$$

Sign convention for amplitude reflection and transmission coefficients

Without losses:
 $t^2 + r^2 = 1$

How do we « observe » ΔL with a Michelson interferometer?

- Input wave $U_i(x, t) = \underline{\mathcal{A}}_i e^{j k x}$
 $= \underline{\mathcal{A}}_i$ on BS
- Beam propagating along x-arm:
 $U_{tx} = \underline{\mathcal{A}}_i t_{BS} e^{j k l_x} \quad (-r_x) e^{j k l_x} \dots\dots$

Sign convention for amplitude reflection and transmission coefficients

Without losses:
 $t^2 + r^2 = 1$

How do we « observe » ΔL with a Michelson interferometer?

- Input wave $U_i(x, t) = \underline{\mathcal{A}}_i e^{j k x}$
 $= \underline{\mathcal{A}}_i$ on BS

- Beam propagating along x-arm:

$$U_{tx} = \underline{\mathcal{A}}_i t_{BS} e^{j k l_x} \quad (-r_x) e^{j k l_x} \quad r_{BS} e^{j k y_s}$$

Sign convention for amplitude reflection and transmission coefficients

Without losses:
 $t^2 + r^2 = 1$

How do we « observe » ΔL with a Michelson interferometer?

- Input wave $U_i(x, t) = \underline{\mathcal{A}_i} e^{j k x}$
 $= \underline{\mathcal{A}_i}$ on BS

- Beam propagating along x-arm:

$$\begin{aligned}
 U_{tx} &= \underline{\mathcal{A}_i} t_{BS} e^{j k l_x} \quad (-r_x) e^{j k l_x} \quad r_{BS} e^{j k y_s} \\
 &= \underline{\mathcal{A}_i} t_{BS} r_{BS} (-r_x) e^{2 j k l_x} e^{j k y_s} \\
 &= \frac{\underline{\mathcal{A}_i}}{2} \times \underbrace{(-r_x e^{2 j k l_x})}_{\text{Complex reflection of the x-arm}} e^{j k y_s} \quad \text{with } t_{BS} = r_{BS} = \frac{1}{\sqrt{2}}
 \end{aligned}$$

Complex reflection of the x-arm

interferometer?

- Input wave $U_i(x, t) = \underline{\mathcal{A}_i} e^{j k x}$
 $= \underline{\mathcal{A}_i}$ on BS

- ## Beam propagating along x-arm:

$$\begin{aligned} U_{tx} &= \underline{\mathcal{A}_i} t_{BS} e^{\mathbf{j}kl_x} \quad (-r_x) e^{\mathbf{j}kl_x} \quad r_{BS} e^{\mathbf{j}ky_s} \\ &= \underline{\mathcal{A}_i} t_{BS} r_{BS} (-r_x) e^{2\mathbf{j}kl_x} e^{\mathbf{j}ky_s} \\ &= \frac{\mathcal{A}_i}{2} \times \underbrace{\left(-r_x e^{2\mathbf{j}kl_x} \right)} \end{aligned}$$

Complex reflection of the x-arm

- ## Beam propagating along y-arm:

$$U_{ty} = -\frac{\mathcal{A}_i}{2} \times \underbrace{\left(-r_y e^{2jkl_y}\right)}_{\text{}} e^{jky_s}$$

Complex reflection of the y-arm

Diagram illustrating a quantum communication setup (likely a Mach-Zehnder interferometer) involving a beam splitter (BS) and mirrors.

- Input beam:** Enters from the left with energy U_i .
- Beam Splitter (BS):** Splits the input beam into two paths.
- Path 1 (Vertical):** Travels a distance l_y to a mirror (blue rectangle) at position r_y .
- Path 2 (Horizontal):** Travels a distance l_x to a mirror (blue rectangle) at position r_x .
- Recombination:** The beams reflect back to the BS and recombine.
- Transmitted beam:** Exits downwards with energy U_t .
- Sensor:** Detects the transmitted beam.
- Coordinate System:** A Cartesian coordinate system (x, y) is shown at the bottom right.

Transmitted field:

$$\begin{aligned}
 U_t &= U_{tx} + U_{ty} \\
 &= \frac{A_i}{2} e^{jky_s} \left(r_y e^{2jkl_y} - r_x e^{2jkl_x} \right)
 \end{aligned}$$

Transmitted field:

$$\begin{aligned} U_t &= U_{tx} + U_{ty} \\ &= \frac{A_i}{2} e^{jky_s} \left(r_y e^{2jkl_y} - r_x e^{2jkl_x} \right) \end{aligned}$$

Simple Michelson interferometer: transmitted power

Field transmitted by the interferometer

$$U_t = \frac{A_i}{2} (r_y e^{2jk l_y} - r_x e^{2jk l_x})$$

k is the wave number, $k = 2\pi/\lambda$

λ is the laser wavelength ($\lambda=1064$ nm)

Transmitted power

$$P_t \propto |U_t|^2 = \frac{P_{max}}{2} (1 - C \cos(\Delta\phi))$$

where $\Delta\phi = 2k(l_y - l_x)$

ITF contrast: $C = \frac{2r_x r_y}{r_x^2 + r_y^2}$

$$P_{max} = \frac{P_i}{2} (r_x^2 + r_y^2)$$

What power does Virgo measure?

- In general, the beam is not a plane wave but a spherical wave
 - interference pattern
(and the complementary pattern in reflection)
- Virgo interference pattern much larger than the beam size:
 - ~1 m between two consecutive fringes
 - we do not study the fringes in nice images !

Equivalent size of Virgo beam

Setting a working point

Controlled mirror positions

From the power to the gravitational wave

$$P_t = \frac{P_i}{2} (1 - C \cos(\phi)) \quad \text{where } \phi = 2\frac{2\pi}{\lambda}(l_y - l_x)$$

- Around the working point:

$$\left. \frac{dP_t}{d\phi} \right|_{\phi_0} = \frac{P_i}{2} C \sin(\phi_0) \quad \text{where } \phi_0 = \frac{4\pi}{\lambda} \Delta L_0$$

- Power variations as function of small differential length variations:

$$\delta P_t = \frac{P_i}{2} C \sin(\phi_0) \delta \phi$$

$$\delta P_t = P_i C \frac{2\pi}{\lambda} \sin\left(\frac{4\pi}{\lambda} \Delta L_0\right) \delta \Delta L$$

$$\delta P_t \propto \delta \Delta L = h L_0 \quad \text{around the working point !}$$

From the power to the gravitational wave

- Around the working point:

$$\delta P_t = P_i C \frac{2\pi}{\lambda} \sin\left(\frac{4\pi}{\lambda} \Delta L_0\right) \delta \Delta L$$

$$\delta P_t = \underbrace{\left(\text{Interferometer response}\right)}_{\text{(W/m)}} \times \delta \Delta L$$

↓
Measurable physical quantity

↑
Physical effect to be detected

Improving the interferometer sensitivity

$$\delta P_t = \underbrace{P_i}_\text{green circle} C \sin\left(\frac{4\pi}{\lambda} \Delta L_0\right) \underbrace{(k \delta \Delta L)}_{\propto \delta \phi}$$

Increase the input power on BS

Increase the phase difference between the arms for a given differential arm length variation

Beam resonant inside the cavities

$$P_c = P_i \frac{t_1^2}{(1 - r_1 r_2)^2} \frac{1}{1 + \left(\frac{2\mathcal{F}}{\pi}\right)^2 \sin^2(kL)}$$

$$\text{Finesse } \mathcal{F} = \frac{\pi \sqrt{r_1 r_2}}{1 - r_1 r_2}$$

Virgo cavity at resonance: $L = n \frac{\lambda}{2} \quad (n \in \mathbb{N})$

Virgo $\mathcal{F} = 50$
AdVirgo $\mathcal{F} = 443$

Average number of light round-trips in the cavity:

$$N = \frac{2\mathcal{F}}{\pi}$$

How do we amplify the phase offset?

$$r_{FPx} = -1 \times e^{j \frac{2\mathcal{F}}{\pi} 2k \delta L_x}$$

~number of round-trips in the arm
~300 for AdVirgo

(instead of $r_{armx} = -1 \times e^{j2k(L_x + \delta L_x)}$ in the arm of a simple Michelson)

How do we increase the power on BS?

Detector working point close to a dark fringe
 → most of power go back towards the laser

Resonant power recycling cavity

$$G_{PR} = 38 \quad (r_{PR}^2 = 0.95)$$

→ input power on BS
 increased by a factor 38!

Improved interferometer response

- Response of simple Michelson:

$$\delta P_t = P_i C \frac{2\pi}{\lambda} \sin\left(\frac{4\pi}{\lambda} \Delta L_0\right) \delta \Delta L$$

$$\delta P_t = (\text{Michelson response}) \times \delta \Delta L \quad (\text{W/m})$$

- Response of recycled Michelson with Fabry-Perot cavities:

$$\delta P_t = \underbrace{G_{PR}}_{\sim 38} P_i C \frac{2\pi}{\lambda} \sin\left(\frac{4\pi}{\lambda} \Delta L_0\right) \underbrace{\frac{2\mathcal{F}}{\pi}}_{\sim 300} \delta \Delta L$$

**For the same $\delta \Delta L$,
 δP_t has been increased by a factor ~ 12000**

Order of magnitude of the « sensitivity »

$$\delta P_t = G_{PR} P_i C \frac{2\pi}{\lambda} \sin\left(\frac{4\pi}{\lambda} \Delta L_0\right) \frac{2\mathcal{F}}{\pi} \delta \Delta L$$

Laser wavelength	$\lambda = 1064 \text{ nm}$
Input power	$P_i \sim 100 \text{ W}$
Interferometer contrast	$C \sim 1$
Cavity finesse	$\mathcal{F} \sim 450$
Power recycling gain	$G_{PR} \sim 38$
Working point	$\Delta L_0 \sim 10^{-11} \text{ m}$

Shot noise due to output power of $\sim 50 \text{ mW}$
 $\rightarrow \delta P_{t,min} \sim 0.1 \text{ nW}$ $\longrightarrow$

$$\delta \Delta L_{min} \sim 5 \times 10^{-20} \text{ m}$$

$$\rightarrow h_{min} = \frac{\delta \Delta L_{min}}{L} \sim 10^{-23}$$

In reality, the detector response depends on frequency...

Example of frequency dependency of the ITF response

- Light travel time in the cavities must be taken into account
- Fabry-Perot cavities behave as a low pass filter
- Frequency cut-off:

$$f_c = \frac{c}{4\mathcal{F}L}$$

Ratio between the sensitivity of an interferometer with Fabry-Perot cavities versus the sensitivity of an interferometer without cavities

- Finesse of Virgo Fabry Perot cavities: $F = 450$, $L = 3$ km $\rightarrow f_c = 55$ Hz

Optical layout of Virgo

How do we control the working point?

Small offset from a dark fringe: $\Delta L_0 = n \frac{\lambda}{2} + 10^{-11} \text{ m}$

- Controls to reduce the motion up to $\sim 100 \text{ Hz}$
- Precision of the control $\delta \Delta L_{true} \sim 10^{-15} \text{ m}$

How do we control the working point?

Small offset from a dark fringe: $\Delta L_0 = n \frac{\lambda}{2} + 10^{-11} \text{ m}$

- Controls to reduce the motion up to $\sim 100 \text{ Hz}$
- Precision of the control $\delta \Delta L_{true} \sim 10^{-15} \text{ m}$

$$\delta \Delta L_{ext} = \delta \Delta L_{noise} + \delta \Delta L_{GW}$$

Many other control loops required: control of the laser frequency & intensity, cavities maintained at resonance, mirrors angular controls, ...

From the detector data to the GW strain $h(t)$

- High frequency (>100 Hz): mirrors behave as free falling masses

$$\rightarrow h(t) = \frac{\delta \Delta L_{true}(t)}{L_0}$$

- Lower frequency: the controls attenuate the noise... but also the GW signal!

$\rightarrow$ the control signals contain information on $h(t)$

How to extract all error signals?

Interferometer optical ports

Table of Contents

- **Principles:**
 - Effect of GW on free-fall masses
 - Basic detection principle overview
- **Virgo optical configuration or how to measure 10^{-20} m**
 - Simple Michelson interferometer
 - How do we improve the detector sensitivity?
 - How to measure the GW strain $h(t)$ from this detector?
- **Noises limiting the ITF sensitivity: how to tackle them?**
- **Prospectives for interferometers and other detectors**

What is noise in GW detectors ?

- Stochastic (random) signal that contributes to the signal $h_{rec}(t)$ but does not contain information on the gravitational wave strain $h_{GW}(t)$

$$h_{rec}(t) = h_{noise}(t) + h_{GW}(t)$$

How do we characterize noise?

Data points (noise)

Distribution of the data

→ Noise characterised by its standard deviation σ_x

$$\sigma_x = \frac{D}{\sqrt{\text{average duration}}}$$

D is in (Data units $\times \sqrt{s}$)
or $\frac{\text{Data units}}{\sqrt{\text{Hz}}}$

→ its absolute value is equal to the standard deviation of the noise when it is averaged over 1 s

→ $D = 1 \text{ units}/\sqrt{\text{Hz}}$

How do we characterize a noise... in frequency domain?

$$\begin{array}{ccc}
 \text{Discrete Fourier Transform (DFT)} \\
 s(n) \xrightarrow{\hspace{1.5cm}} S(k) = A(k)e^{j\Phi(k)} \\
 \text{Sampled signal} \hspace{15cm} \text{Fourier spectrum}
 \end{array}$$

→ Noise characterised by the fluctuations of its Fourier spectrum

$$\rightarrow D(k) \text{ in units/VHz}$$

Assumption: noise is random and ergodic

→ noise characterised by its **amplitude spectral density** (ASD)

$$ASD = \sqrt{PSD} = \sqrt{\frac{|DFT|^2}{T}}$$

Data vs time

Noise distribution

Noise ASD

Random gaussian noise
1 count/VHz

Sampled at 10 kHz

From hrec(t) to Virgo sensitivity curve

1/ Reconstruction of $h(t)$

$$h_{rec}(t) = h_{noise}(t) + h_{GW}(t)$$

2/ Amplitude spectral density of $h(t)$
(noise standard deviation over 1 s)

$$ASD = \sqrt{PSD} = \sqrt{\frac{|DFT|^2}{T}}$$

Discrete Fourier Transform (DFT)

$\sim 10^{-19}$ m/ $\sqrt{\text{Hz}}$ (Virgo, 2011)

$\sim 10^{-20}$ m/ $\sqrt{\text{Hz}}$ (Advanced Virgo, 2020)

Image: Danna Berry/SkyWorks/NASA

Compact Binary Coalescences

Signal lasts for a few seconds

→ can detect $h \sim 10^{-23}$

R. Gouaty - GraSPA 2026 - Annecy

Image: B. Saxton (NRAO/AUI/NSF)

Rotating neutron stars

Signal averaged over days ($\sim 10^6$ s)

→ can detect $h \sim 10^{-26}$

Nominal sensitivity of Advanced Virgo

Fundamental noise only

Possible technical noise not shown

Fundamental noise sources

Under vacuum

Goals

- ❑ Isolation against acoustic noise
- ❑ Avoid measurement noise due to fluctuations of air refractive index
- ❑ Keep mirrors clean

Advanced Virgo vacuum in a few numbers:

- ❑ Volume of vacuum system: 7000 m³
- ❑ Different levels of vacuum:
 - 3 km arms designed for up to 10^{-9} mbar (Ultra High Vacuum)
 - $\sim 10^{-6}$ - 10^{-7} mbar in mirror vacuum chambers (« towers »)
- ❑ Separation between arms and towers with cryotrap links

Seismic noise and suspended mirrors

Ground vibrations up to $\sim 1 \mu\text{m}/\sqrt{\text{Hz}}$ at low frequency decreasing down to $\sim 10 \text{ pm}/\sqrt{\text{Hz}}$ at 100 Hz

$\gg 10^{-19} \text{ m}/\sqrt{\text{Hz}}$ needed to detect GW !!

Assuming δx_H small and sinusoidal and θ small:

$$\underline{x_M} = \underline{\mathcal{H}} \times \underline{x_H}$$

Transfer function

Seismic noise: Virgo super-attenuators

Passive attenuation: 7 pendulum in cascade

$$\text{At } 10 \text{ Hz: } \frac{x_{\text{mirror}}}{x_{\text{ground}}} \sim (10^{-2})^7 = 10^{-14}$$

$$x_{\text{ground}} \sim 10^{-9} \text{ m}/\sqrt{\text{Hz}}$$

$$\rightarrow x_{\text{mirror}} \sim 10^{-23} \text{ m}/\sqrt{\text{Hz}}$$

This noise directly modifies the positions of the mirror surfaces, and thus $\delta\Delta L$ and $h_{\text{rec}}(t)$!

Active controls at low frequency

- Accelerometers or interferometer data
- Electromagnetic actuators
- Control loops

Thermal noise (pendulum and coating)

Microscopic thermal fluctuations

→ dissipation of energy through excitation of the macroscopic modes of the mirror

Pendulum mode $f < 40$ Hz
 "Mirror" mode $f > \text{few kHz}$
 "Violin" modes $f > 40$ Hz

This noise directly modifies the positions of the mirror surfaces, and thus $\delta\Delta L$ and $h_{rec}(t)$!

We want high quality factors Q to concentrate all the noise in a small frequency band

Reduction of thermal noise: monolithic suspensions

- Increase the quality factor of the mirrors (with respect to steel wires)
- **Monolithic suspension** developed in labs in Perugia and Rome

Fused-silica fibers:

- Diameter of 400 μm
- length of 0.7 m
- Load stress: 800 Mpa

Reduction of thermal noise: mirror coating

40 kg mirrors of Advanced Virgo
35 cm diameter, 40 cm width
Suprasil fused silica

- Currently the main source of thermal noise
- Very high quality mirror coating developed in a lab close to Lyon (Laboratoire des Matériaux Avancés)
- R&D to improve mechanical properties of coating
- Cryogenics mirrors (at Kagra, future detectors)
 - other substrate
 - other coating
 - other wavelength

Thermal noise: coupling reduction

- Reduce the coupling between the laser beam and the thermal fluctuations
 - **use large beams**: fluctuations averaged over larger surface
 - Thermal Noise $\sim 1/D$, with D = beam diameter
- Impact of large beams:
 - Require large mirrors (and heavier):
 - > Advanced Virgo beam splitter diameter = 55 cm
 - High magnification telescopes to adapt beam size to photodetectors (from $w=50$ mm on mirrors to $w=0.3$ mm on sensors) > require optical benches

Shot noise

Fluctuations of arrival times of photons (quantum noise)

Power received by the photodiode: P_t

→ $N = \frac{P_t}{h\nu}$ photons/s on average.

Standard deviation on this number: $\sigma_N = \sqrt{N}$

→ $\sigma_{P_t} = \sigma_N \times h\nu = \sqrt{\frac{P_t}{h\nu}} h\nu = \sqrt{P_t h\nu}$

Virgo laser: $\lambda = 1.064 \mu\text{m} \rightarrow \nu = \frac{c}{\lambda} \sim 2.8 \times 10^{14} \text{ Hz}$

Working point: $P_t \sim 80 \text{ mW} \rightarrow \sigma_{P_t} = 0.1 \text{ nW}/\sqrt{\text{Hz}}$

→ a variation of power is interpreted as a variation of distance $\delta\Delta L$

$$\delta P_t = (\text{Virgo response}) \times L_0 \times h \quad h_{\text{equivalent}} = \frac{1}{L_0} \frac{\sigma_{P_t}}{(\text{Virgo response})}$$

(in W/m)

$$\rightarrow \mathbf{h_{\text{equivalent}} \propto 1/\sqrt{P}}$$

Radiation pressure noise

- Radiation pressure: transfer of photon's momentum to the reflective surface (recoil force)
- Radiation pressure noise: due to fluctuations of number of photons hitting the mirror surfaces > mirror motion noise
- Radiation pressure noise impact at low frequency:
 - > Mirror motion filtered by pendulum mechanical response

$$\rightarrow h_{\text{equivalent}} \propto \sqrt{P}$$

Quantum noise in the sensitivity

Minimizing shot noise with optical configuration

Reduction of shot noise: high power laser

Goal for AdV (nominal):

- continuous 200 W laser, stable monomode beam (TEM00), 1064 nm

→ decrease shot noise contribution

But limited by side-effects:

➤ Radiation pressure

- Increase of radiation pressure noise
- Cavities more difficult to control
- Parametric instabilities: coupling of laser high order modes with mirrors mechanical modes

➤ Thermal absorption in the mirrors (optical lensing)

→ Need of thermal compensation system

Avoid optical losses to not spoil high power → high quality mirrors

« Perfect » mirrors

- 40 kg, 35 cm diameter, 20 cm thickness in ultra pure silica
- Uniformity of mirrors is unique in the world:
 - a few nanometers peak-to-valley
 - flatness < 0.5 nm RMS (over 150mm diameter)

Optical field models

Classical picture

Coherent State

Vacuum State

Michelson interferometer at dark fringe and quantum noises

- Operating at dark-fringe :
 - The Input Laser is reflected back to the injection
 - A vacuum field enters the interferometer from the output port
- Shot noise arises from the vacuum state phase fluctuations (ΔX_2)
- Radiation pressure noise arises from the vacuum state amplitude fluctuations (ΔX_1)

Reduction of shot noise: squeezing

Inject a phase-squeezed vacuum state in the interferometer (squeezing)

Already in place during O3 run

→ Decrease shot noise

But increase radiation pressure noise

Reduction of quantum noise: frequency dependent squeezing

→ Decrease shot noise at high freq
AND radiation pressure noise at low freq

Installed in Virgo in 2020-2021

→ new filter cavity of ~300 m, with finesse ~10000

→ strong constraints on optical losses, beam matching and alignment, ...
(suspended in vacuum optical benches)

Example of Advanced Virgo noise budget (O3 run)

Example of technical noise: Scattered light

Optical element
(mirror, lens, ...)
vibrating due to
seismic or acoustic
noises

Incident laser beam

some photons of the scattered
light gets recombined with the
interferometer beam

↓
phase noise

↓
extra power fluctuations
(imprint of the optical element vibrations)

Evolution for AdVirgo: suspend the
optical benches and place them
under vacuum

Noises are not always stationary

“Glitches” are impulses of noise. They might look like a transient GW signal

- ❑ environmental disturbances monitored with an array of sensors: seismic activities, magnetic perturbations, acoustic noises, temperature, humidity
→ used to veto false alarm triggers due to instrumental artifacts
- ❑ requires coincidence between 2 detectors to reduce false alarm rate

Table of Contents

- **Principles:**
 - Effect of GW on free-fall masses
 - Basic detection principle overview
- **Virgo optical configuration or how to measure 10^{-20} m**
 - Simple Michelson interferometer
 - How do we improve the detector sensitivity?
 - How to measure the GW strain $h(t)$ from this detector?
- **Noises limiting the ITF sensitivity: how to tackle them?**
- **Prospectives for interferometers and other detectors**

Range of Advanced detectors

Distance at which a neutron star binary coalescence ($1.4 M_{\odot} - 1.4 M_{\odot}$) can be seen with signal-to-noise ratio of 8

Improving the sensitivity (or range) by a factor 10

Increase the volume (or event rate) by $10^3 = 1000$

LIGO-Virgo ranges (Mpc) during the O4 run (2024)

Observing runs

Einstein Telescope and Cosmic Explorer

- Third generation interferometer: gain another factor 10 in sensitivity and enlarge bandwidth

Einstein Telescope (Europe):

Located underground, with ~ 10 km arms

Cryogenics to reduce thermal noise

Xylophone configuration?

cold + hot interferometers in parallel

Cosmic Explorer (US):

With ~ 40 km arms

In operation after 2036+?

Could probe CBC signals from a large fraction of the Universe

Spatial interferometer: LISA

- **Bandwidth: 0.1 mHz to 1 Hz (2.5 million km arm length)**
- Launch of LISA around 2035?
 - operation for 5 to 10 years
- Successful intermediate step: LISA Pathfinder
 - launched end 2015
 - test of free-fall masses
 - validation of differential motion measurements

ET and LISA performances

LISA and ground based detectors sensitivities

Pulsars timing arrays

- **Bandwidth: 1 nHz to 1000 nHz**
- Observation of 20 ms pulsars in radio
 - GW cause the time of arrival of the pulses to vary by a few tens of nanoseconds over their wavelength
 - Weekly sampling over 5 years
- International network
 - Parkes PTA
 - North American NanoHertz Gravitational Wave Observatory
 - European PTA
- **First detections to be confirmed**

A large GW spectrum to be studied...
