Neutrino Astronomy

Advantages of neutrinos:

Electrically neutral → not bent by the ambient magnetic fields (unlike cosmic-rays)
→ their direction point back to their source

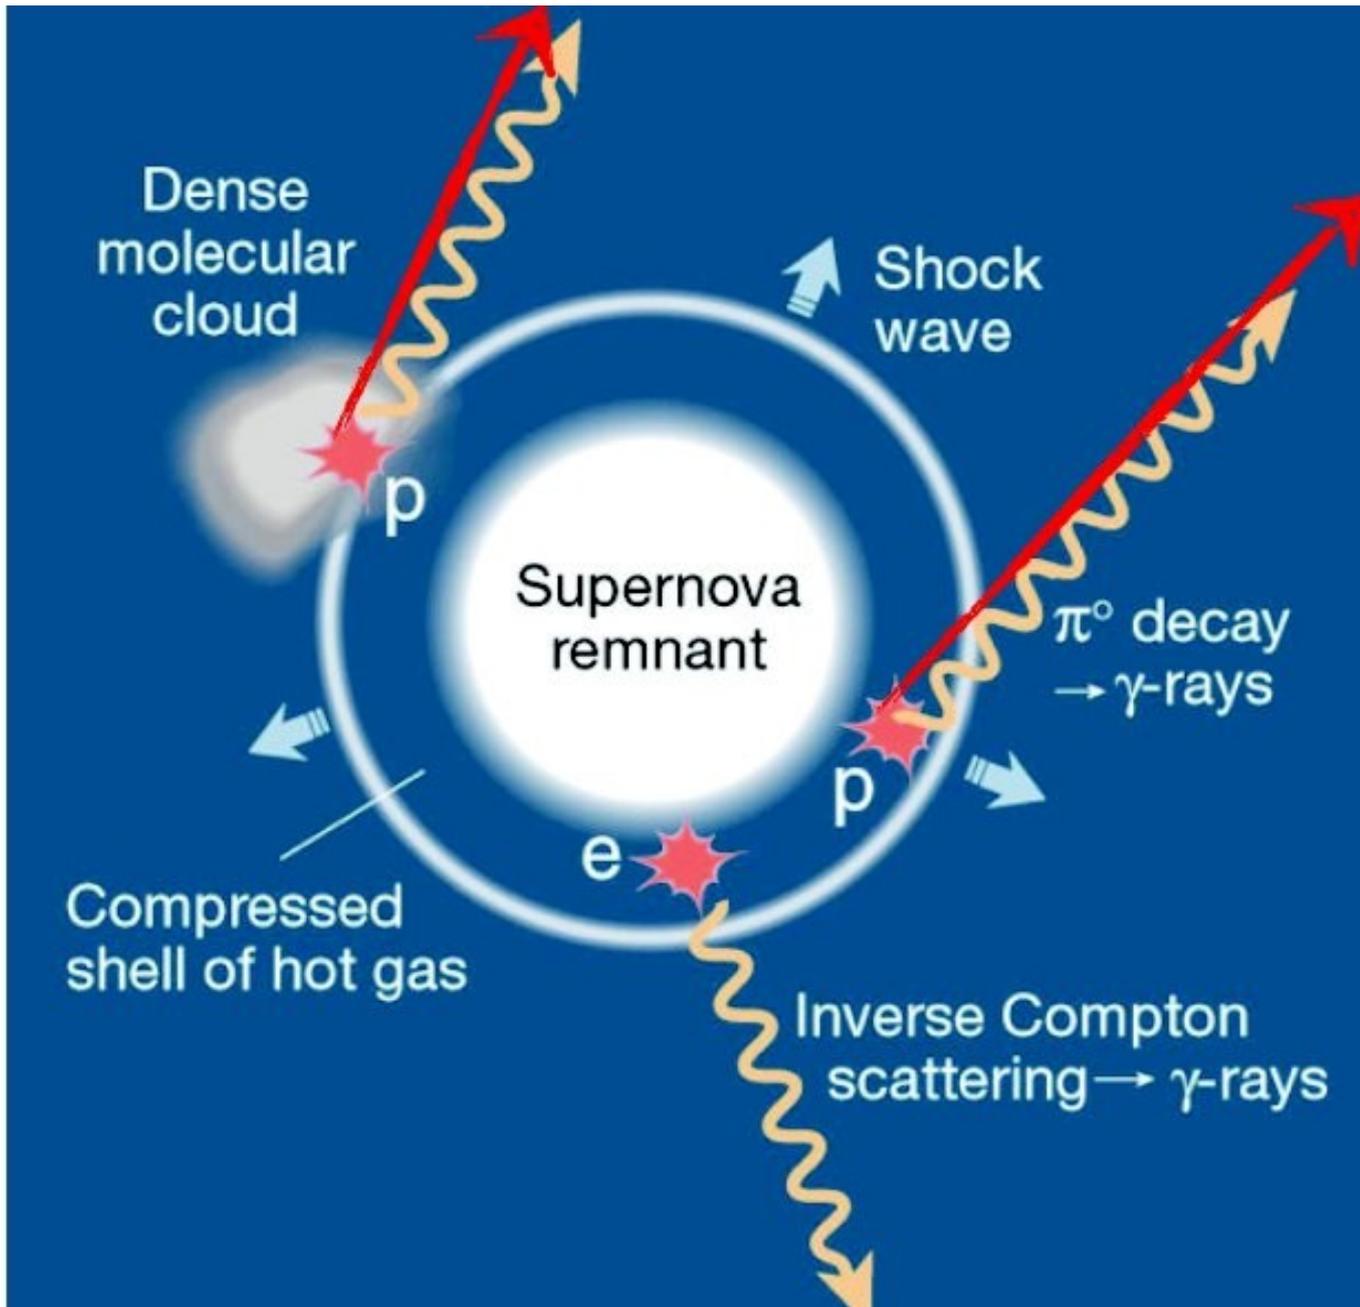

Weakly interacting → No absorption: observation at cosmological distances (unlike photons)
→ escape from the dense areas of the Universe (core of stars, ect.)

→ Neutrinos are an ideal probe to observe distant astrophysical objects and provide information on the dynamics of the most energetic phenomena of the Universe.

→ Neutrino might shed light on the origin of very high energy cosmic rays

Extragalactic and Galactic cosmic-rays accelerators

modified from F.Aharonian, Nature 416, 797-798 (25 April 2002)

$$\Pi^{\pm} \rightarrow \nu$$

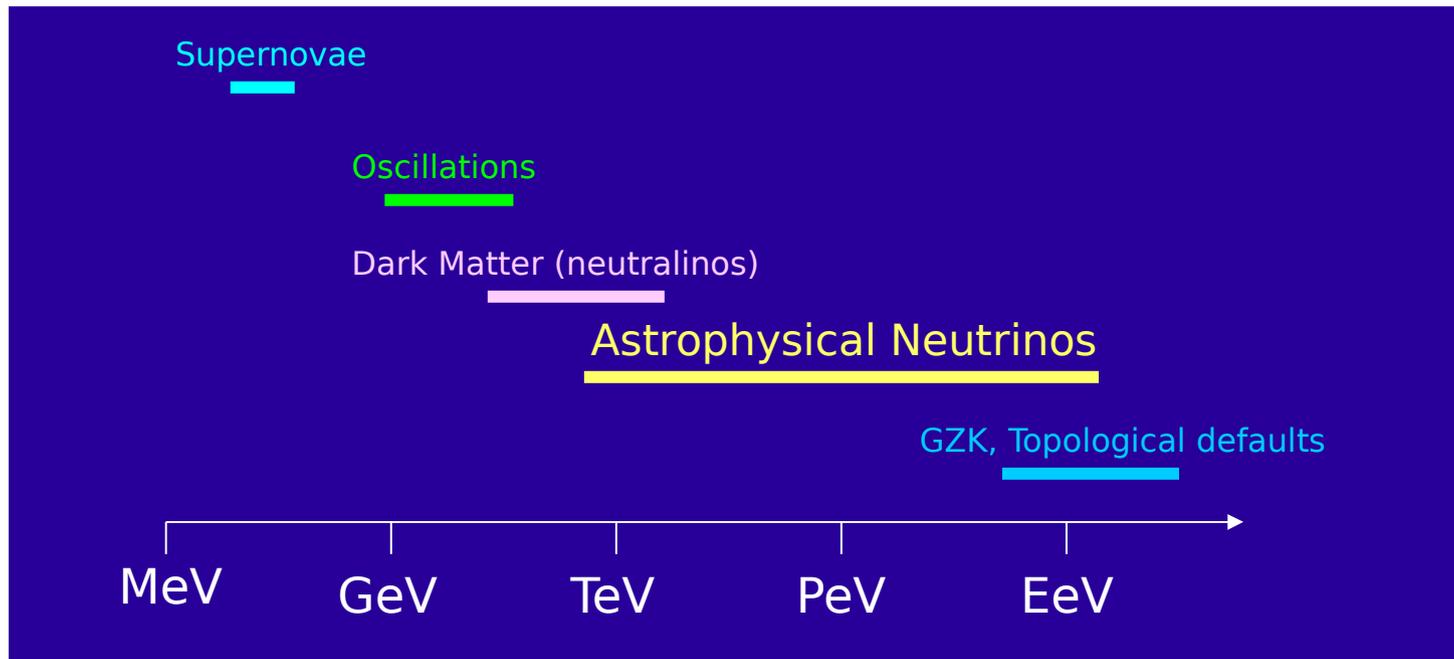

ν not produced
in leptonic
interactions.

Neutrino Astronomy

- Extragalactic/Galactic Cosmic Rays accelerators (AGN, GRBs, microquasars, SNRs)
- Indirect dark matter searches
- Beyond the Standard Model (Lorentz symmetry violation, monopoles ect.)

Specific to IceCube:

- Supernovae explosions
- Primary Cosmic Rays around the Knee (Cosmic Rays anisotropy/Icetop)

Neutrino detection principle

3D photomultiplier array

Cherenkov light from muon

γ

41°

Neutrino are weakly interacting particles:

On 10 billion neutrinos coming from the Sun and crossing the Earth, only 1 will interact!!!

→ A large volume of detection is required

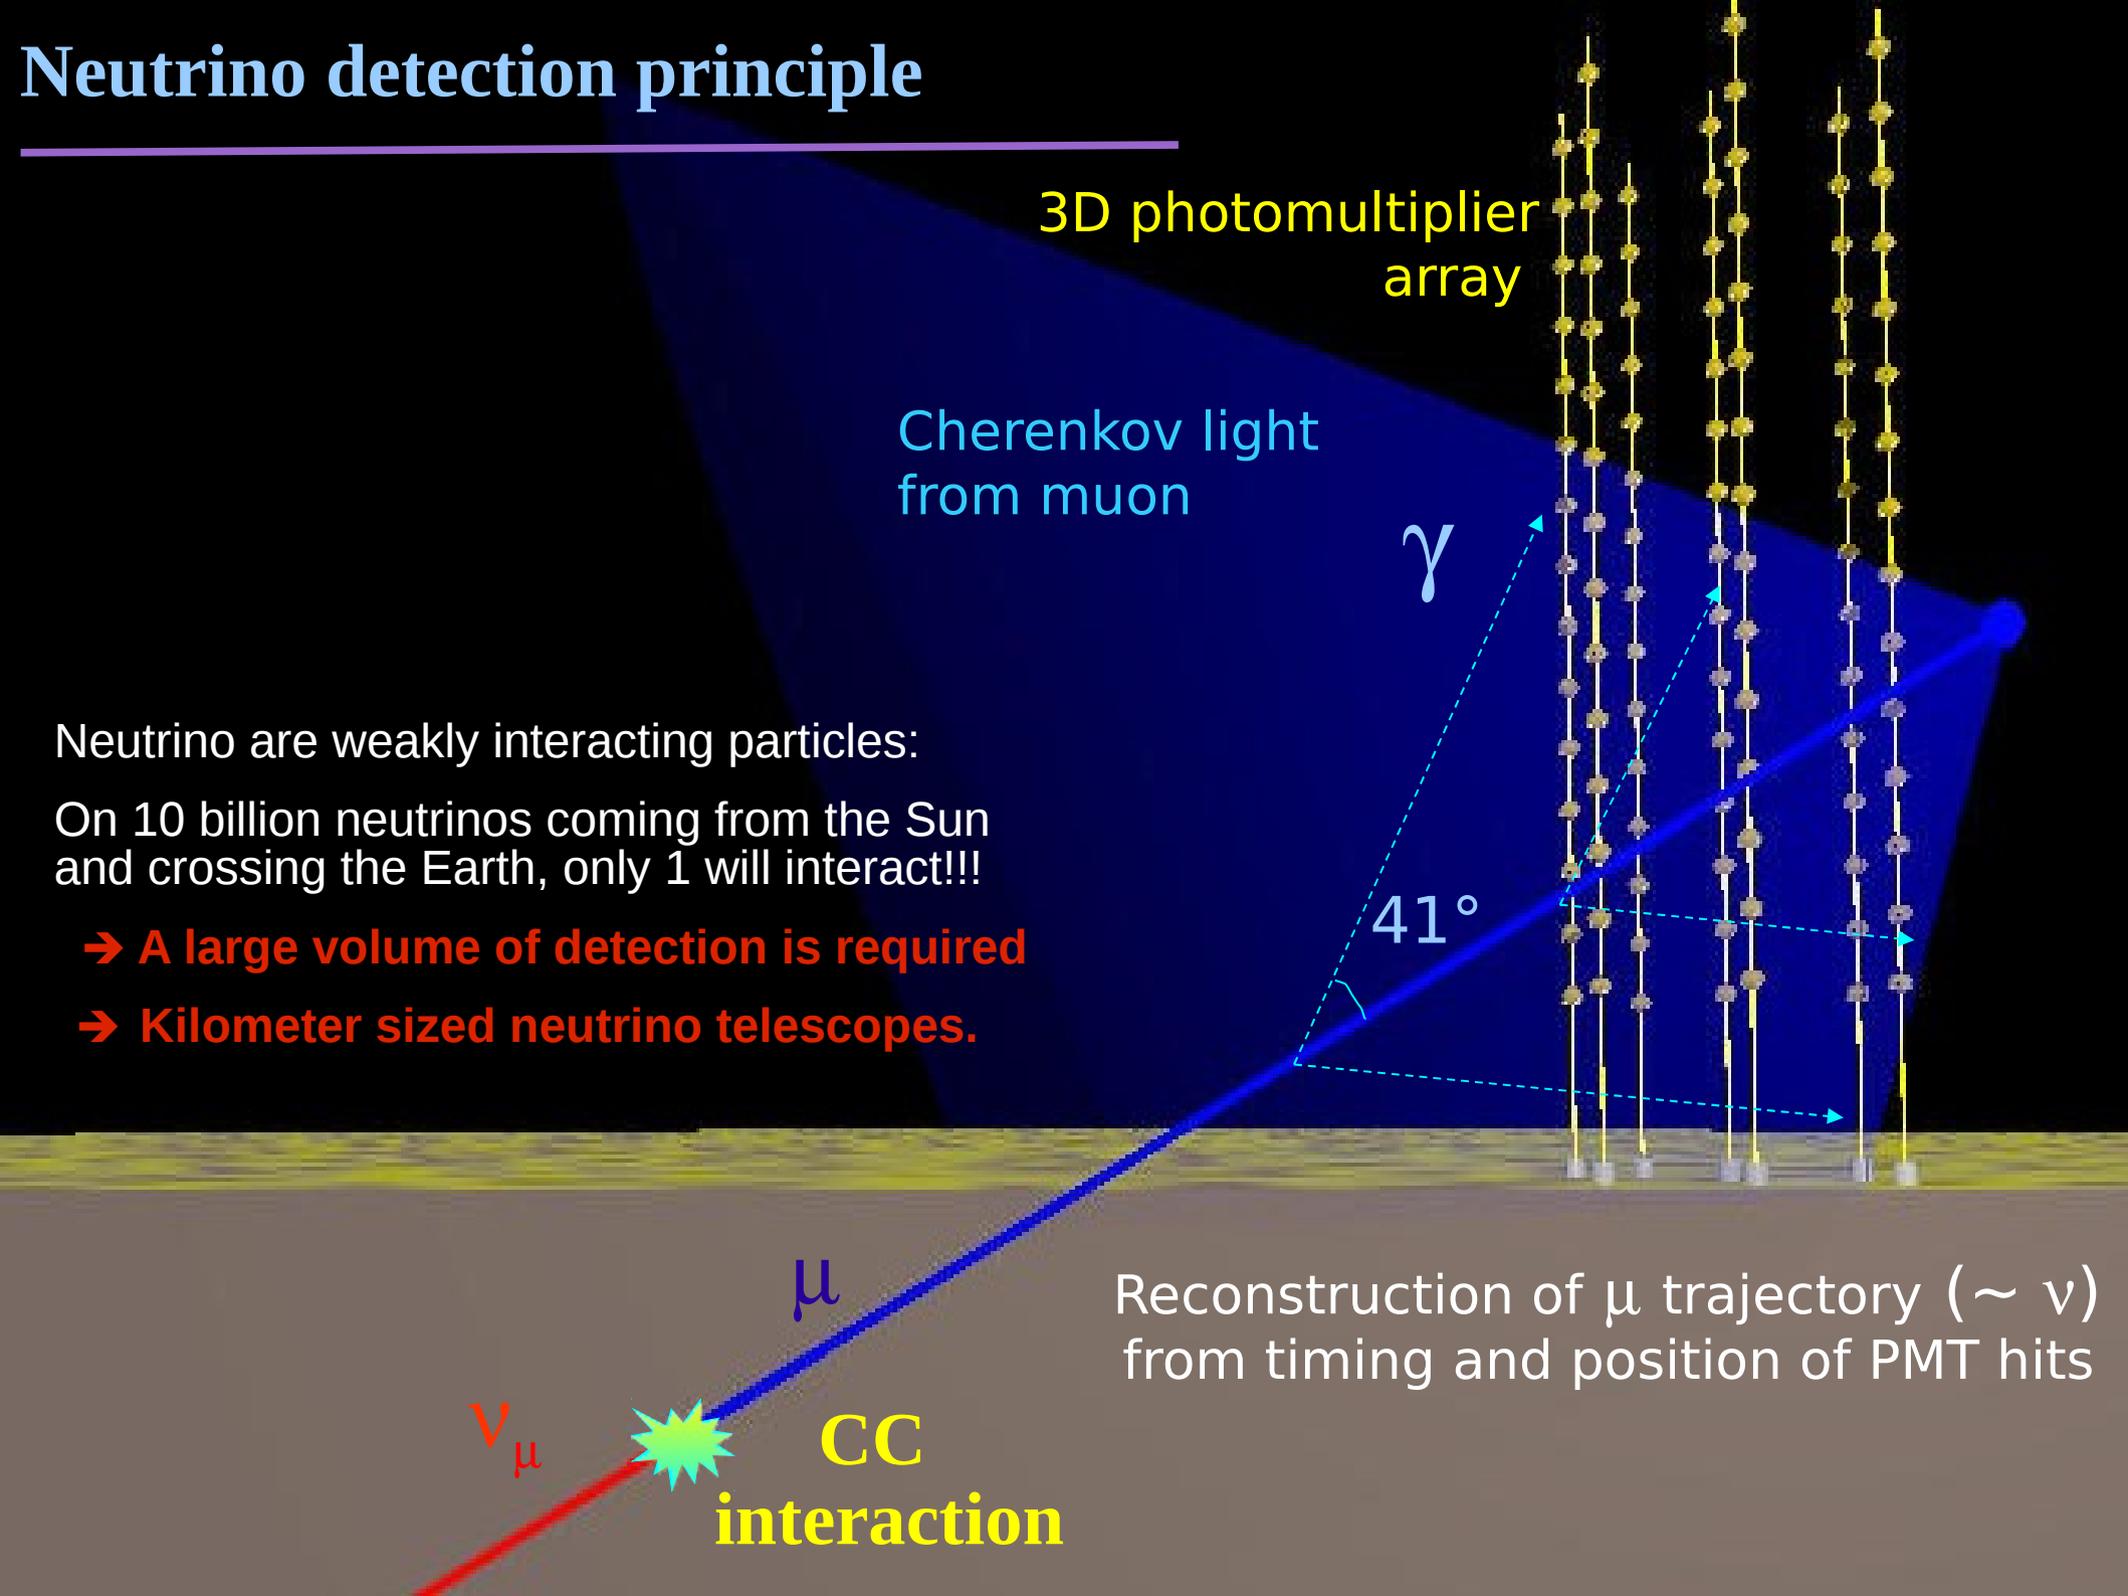

→ Kilometer sized neutrino telescopes.

Reconstruction of μ trajectory ($\sim v$) from timing and position of PMT hits

Cubic Kilometer sized telescopes only

IceCube

An aerial photograph of the IceCube neutrino observatory in Antarctica. The image shows a vast, flat, white ice field under a clear blue sky. A network of detector strings is laid out in a grid pattern across the ice. Several small, dark structures are visible on the ice, likely part of the infrastructure for the observatory.

IceCube

- 5168 DOMs/86 strings

- 60 DOMs/string

- Spacing:

~ 125m between lines

~ 17m between DOMs

- Angular resolution: $\sim 0.4\text{-}1^\circ$

IceCube taken during construction:

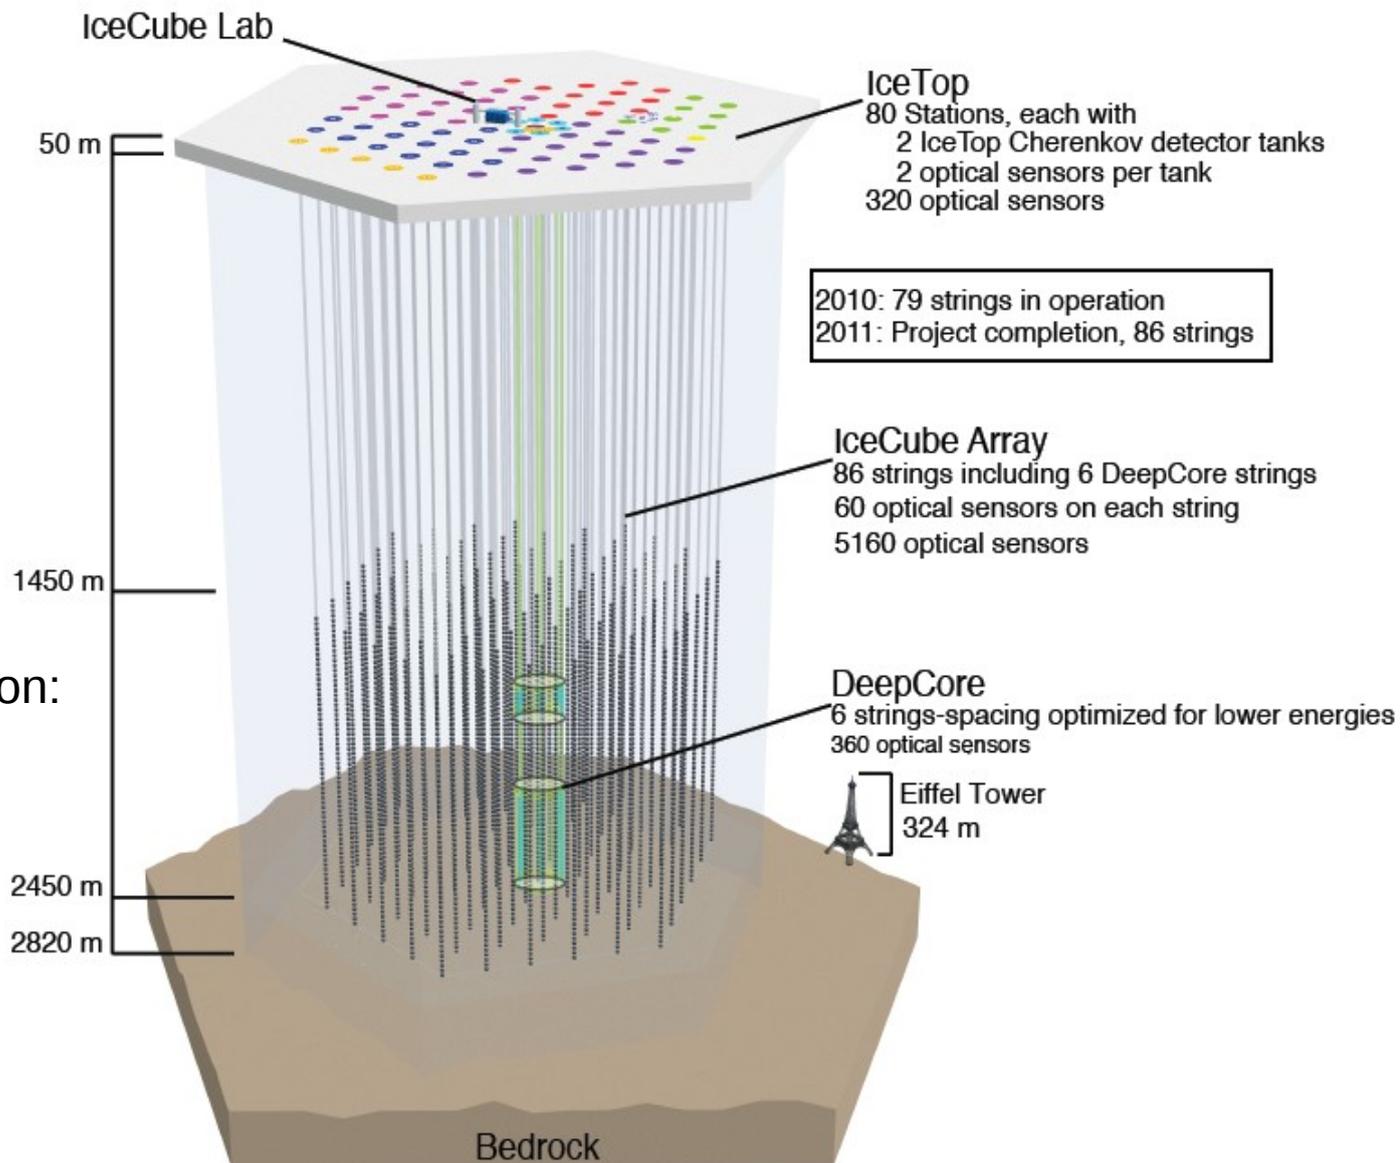

2006-7 data set: IC9

2007-8 data set: IC22

2008-9 data set: IC40

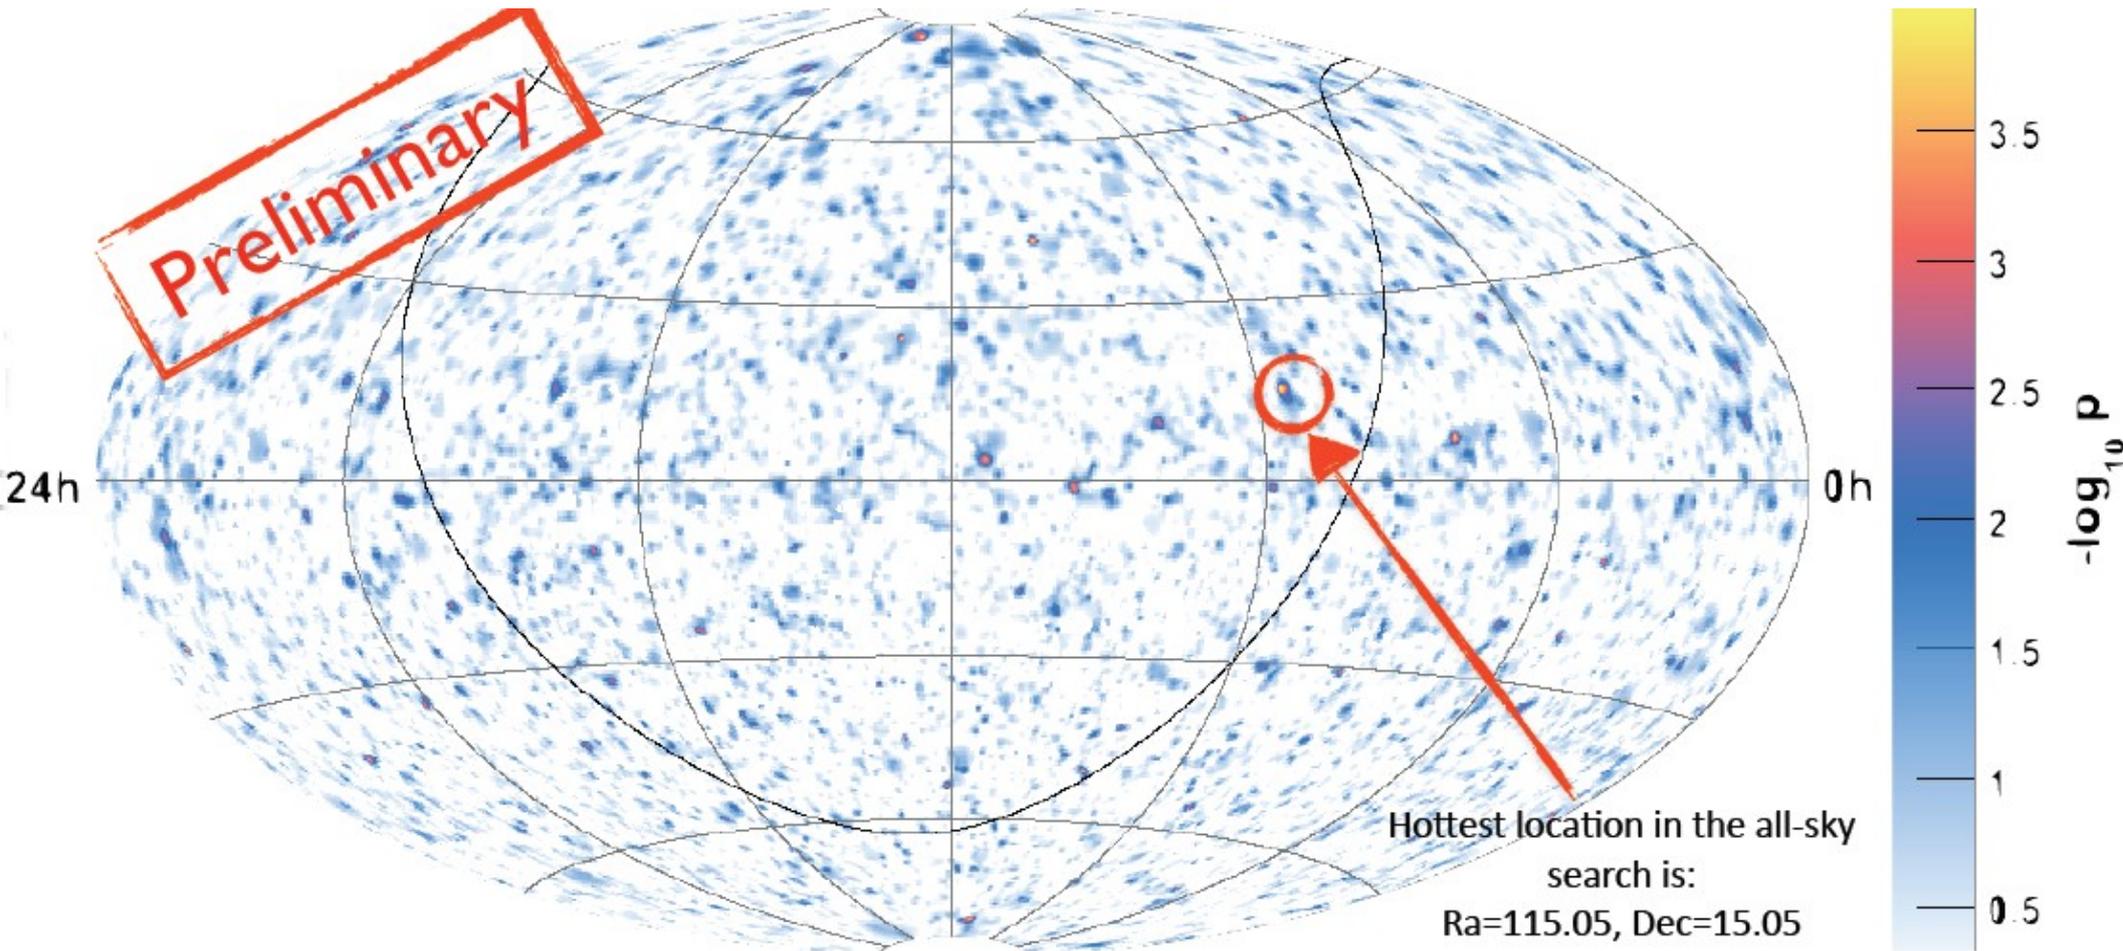

2009-10 data set: IC59

Current configuration: IC79

Point Source Search IC40

Northern Hemisphere
Background: **Atmospheric Neutrinos**

Southern Hemisphere
Background: **Atmospheric Muons**

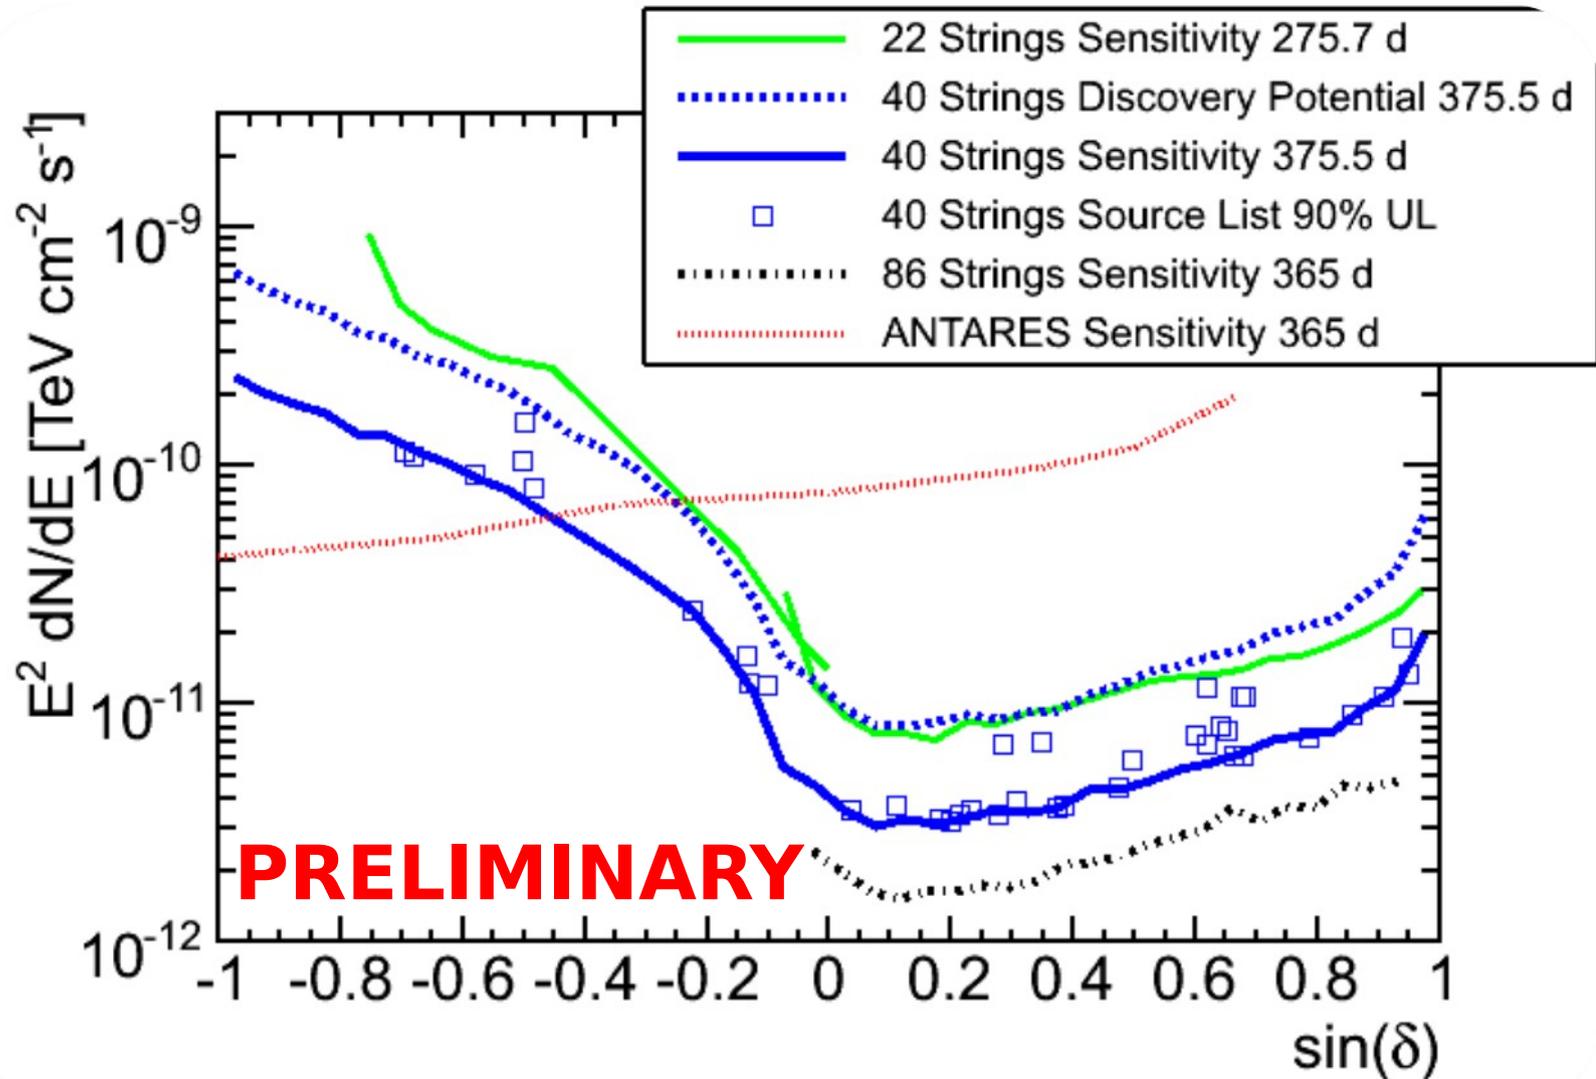

Pre-trials significance

All-sky p-value = 18%
Not significant, no evidence of a neutrino source

Livetime = 375.5 days

Events = 36900
(14121 up-going,
22779 down-going)

Sensitivity at the 90% C.L. for IC40

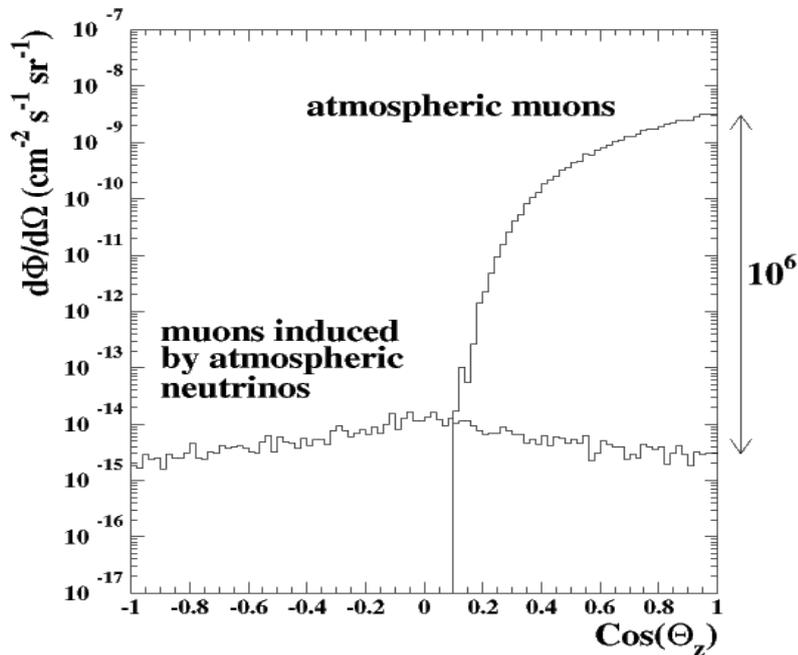

Northern Hemisphere: $E^2 \cdot \Psi(E) \sim 2 - 200 \cdot 10^{-12} \text{ TeV} \cdot \text{cm}^{-2} \cdot \text{s}^{-1} [\text{TeV} - \text{PeV}]$

Southern Hemisphere: $E^2 \cdot \Psi(E) \sim 3 - 700 \cdot 10^{-12} \text{ TeV} \cdot \text{cm}^{-2} \cdot \text{s}^{-1} [E > \text{PeV}]$

IceCube-DeepCore

- The DeepCore detector
- The Atmospheric muon veto
- The Atmospheric neutrino veto
- Application to the Southern Hemisphere

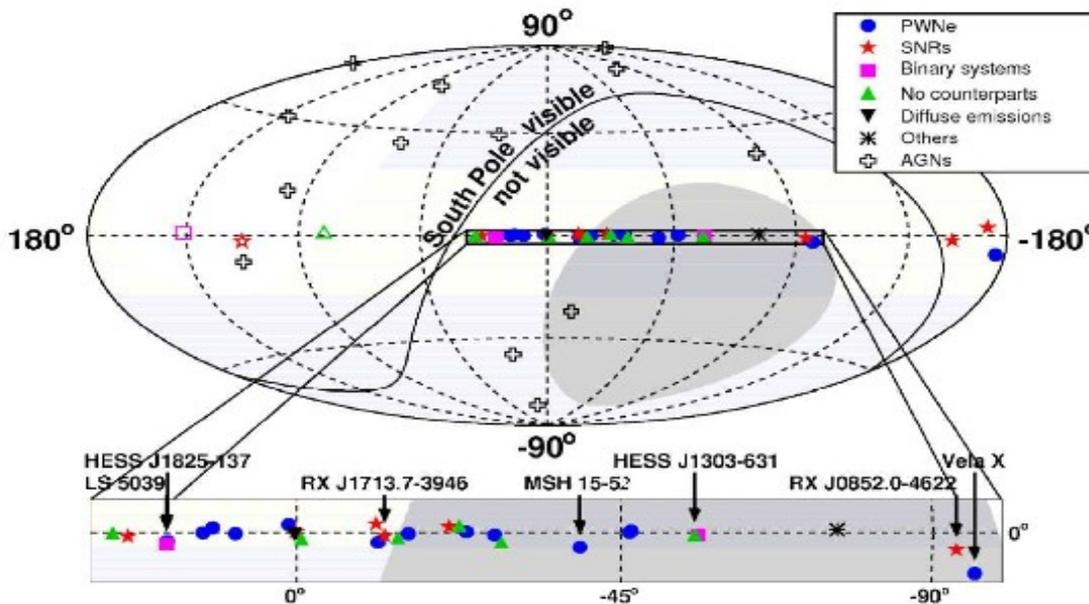

Accessing the Southern Hemisphere below 1 PeV

IceCube is at the **South Pole**.

Field of view ($E_\nu < 1$ PeV):
Northern Hemisphere.

Southern Hemisphere:

At least **5 SNRs** have been detected
+
Galactic Center
+
Many sources to be identified

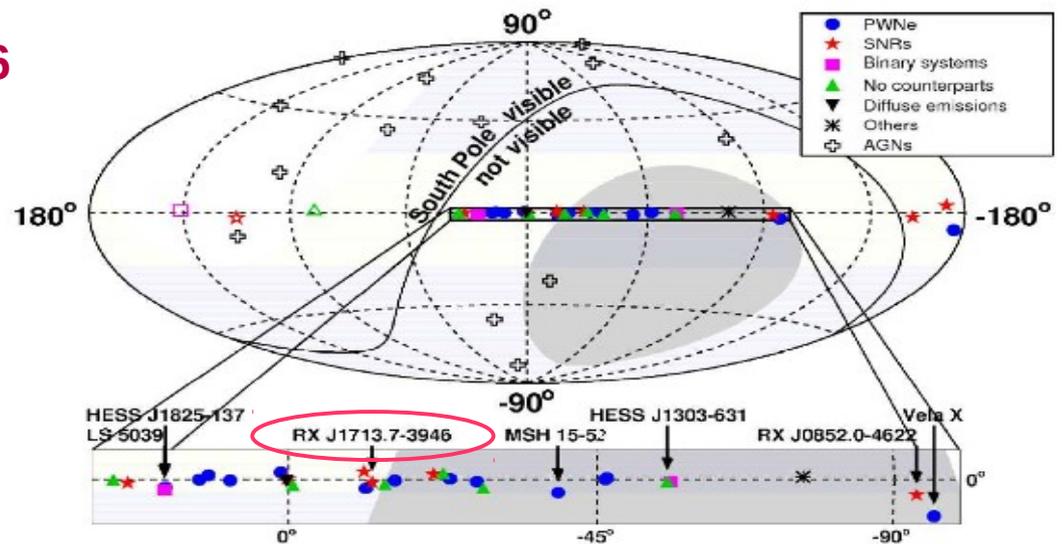

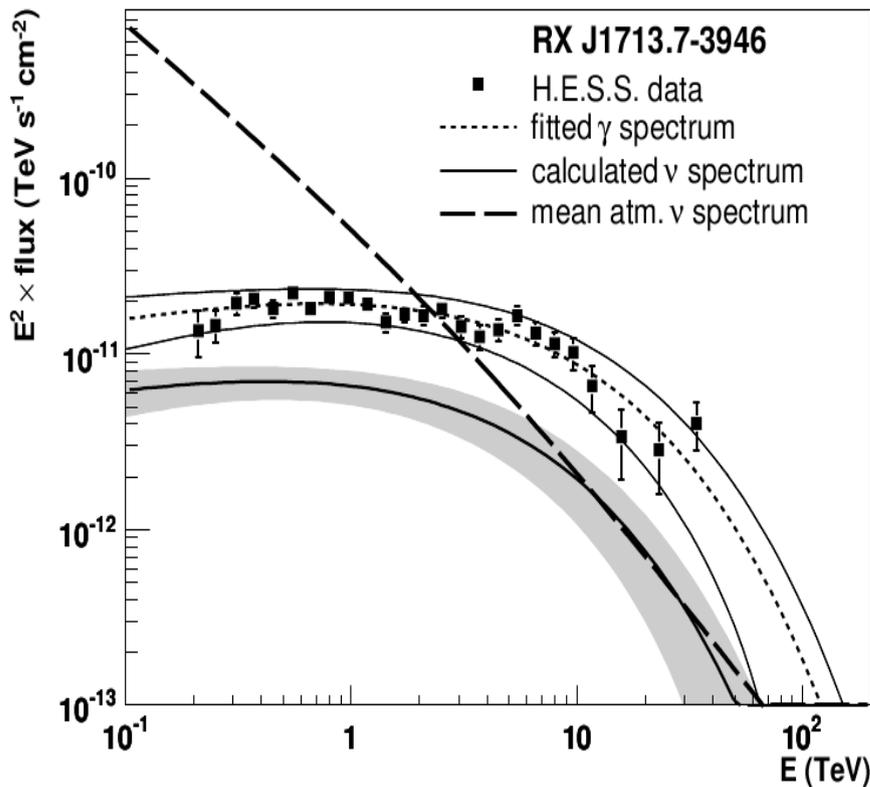

The link to Gamma-Ray Astronomy

Benchmark source: SNR RXJ 1713.7-3946

Right Ascension: 17:13:00 h

Declination: -39:45:00 deg

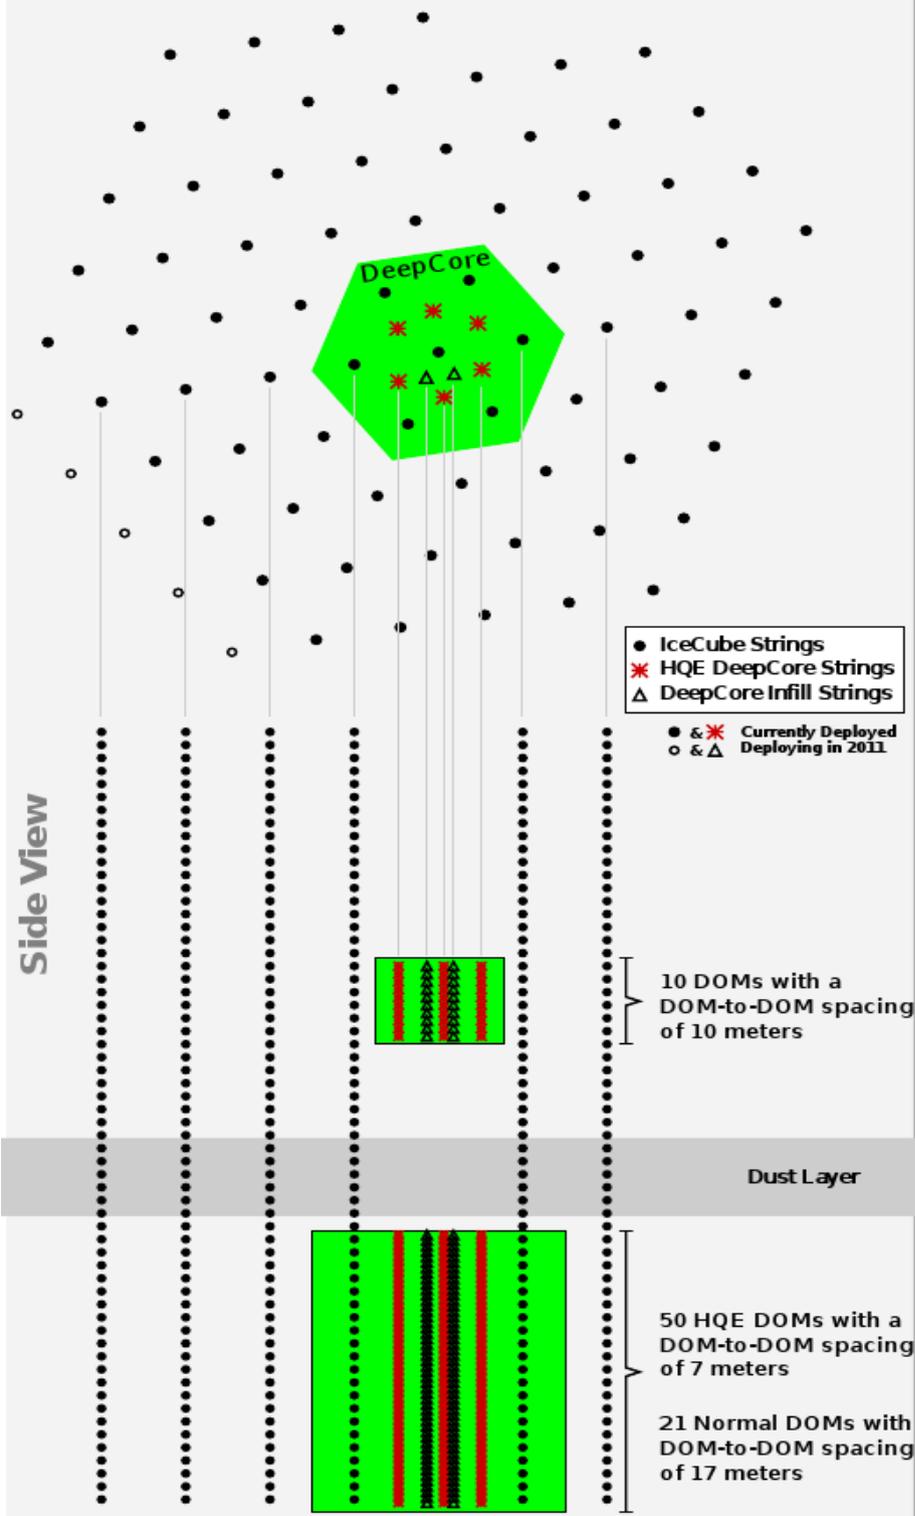

Very young and the brightest SNR of the Southern Hemisphere

The **measured gamma ray spectrum** allows to estimate the **neutrino spectrum**, in the case that they are produced in proton-proton interactions [*astro-ph*]arxiv: 0607286 (2007).

How to open the field of view of IceCube to the Southern Hemisphere for Galactic Neutrino Sources with a soft-spectrum?

$$\frac{dN}{dE_\nu} = 15.52 \left(\frac{E_\nu}{1 \text{ TeV}} \right)^{-1.72} e^{-\sqrt{\frac{E_\nu}{1.35}} 10^{-12} \text{ TeV}^{-1} \cdot \text{cm}^{-2} \cdot \text{s}^{-1}} .$$

The DeepCore detector

- 15 strings/ 60 DOMs each:
 - 6 strings with **40% higher quantum efficiency**
 - 7 surrounding IceCube strings.
 - 2 infill strings with standard IceCube PMTs
- **Denser spacing:** ~70m between the strings
~7m between the DOMs
- **Very clear ice** (twice as clear as the average ice in the upper part of IceCube)
 - ➔ Larger number of photons are recorded.
 - ➔ Improved reconstruction at low energies
- Currently deployed: 7 strings.

The two infill strings will be deployed in the Austral summer 2010/2011.

Purpose:

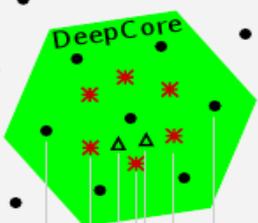

- Enhance the sensitivity of IceCube for **low energies** (< 100 TeV).
- Lower the detection threshold of IceCube by an order of magnitude to energies **as low as 10 GeV**.

Overhead View

The Atmospheric muon Veto

Veto atmospheric muons while keeping a good passing rate of starting neutrinos.

Side View

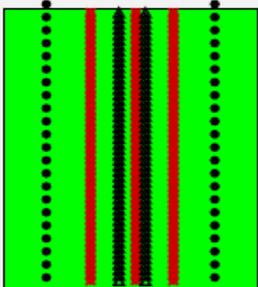

- IceCube Strings
- * HQE DeepCore Strings
- △ DeepCore Infill Strings

● & * Currently Deployed
○ & △ Deploying in 2011

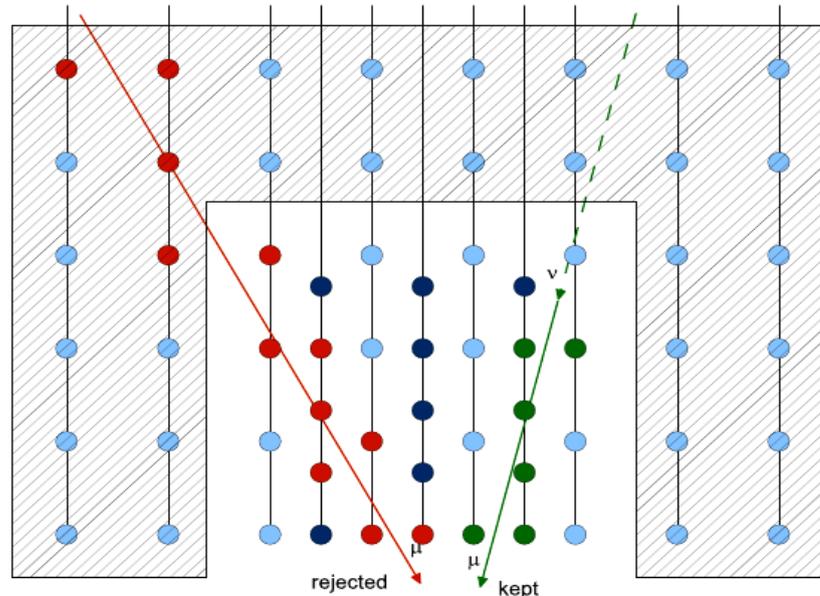

10 DOMs with a DOM-to-DOM spacing of 10 meters

Dust Layer

50 HQE DOMs with a DOM-to-DOM spacing of 7 meters

21 Normal DOMs with DOM-to-DOM spacing of 17 meters

- not hit IceCube DOM
- not hit DeepCore DOM
- / ● hit DOM

Events with hits in the **veto region** (shaded) are treated as atmospheric muon background. Events with hits in the **fiducial region** are signal.

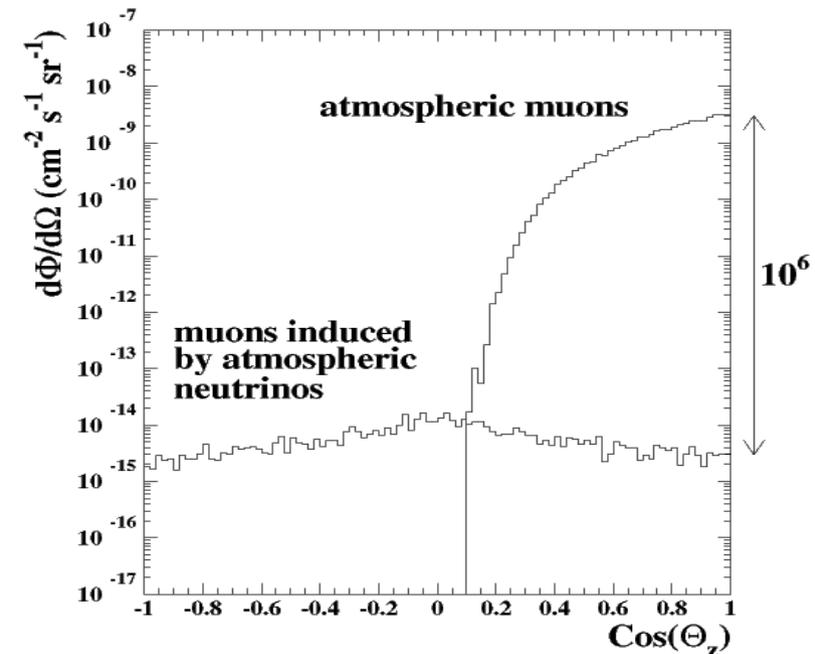

Fiducial Volume: cylinder around **String 36**. **R=200m, H=350m** (6 DC strings + 7 surrounding IC strings + 2 infill IC strings.)

Atmospheric muon Veto: L1 & L2 cuts

- **Level 1 cuts** aim to reduce the atmospheric background for 3-4 orders of magnitude, before reconstruction, using only the topology of the hits.
 - Keep events with **hits only in the Fiducial Volume**
 - Background rejection: $\sim 5 \times 10^{-4}$
- **Level 2 cuts** are based on the output of the vertex reconstruction algorithm.
 - **LLHR** – Likelihood for the track to be starting inside the Fiducial Volume.
 - The reconstructed vertex position is described by the **Z-coordinate** and the **radius R** from the center of DeepCore:

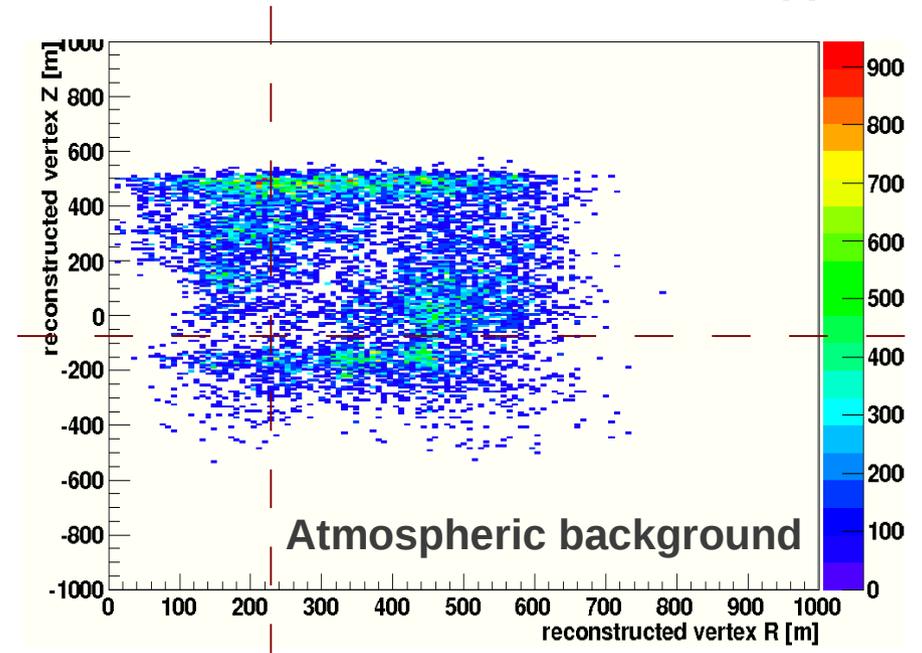

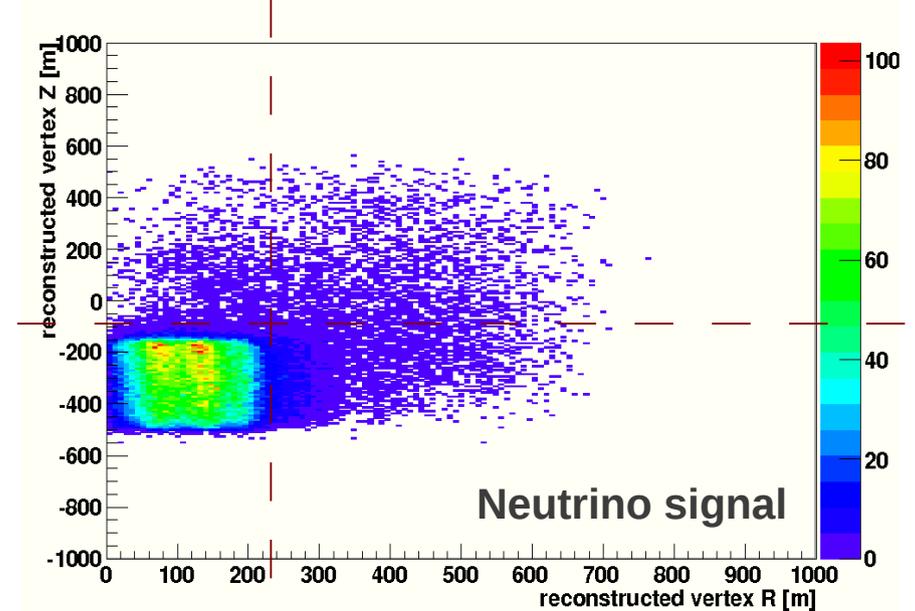

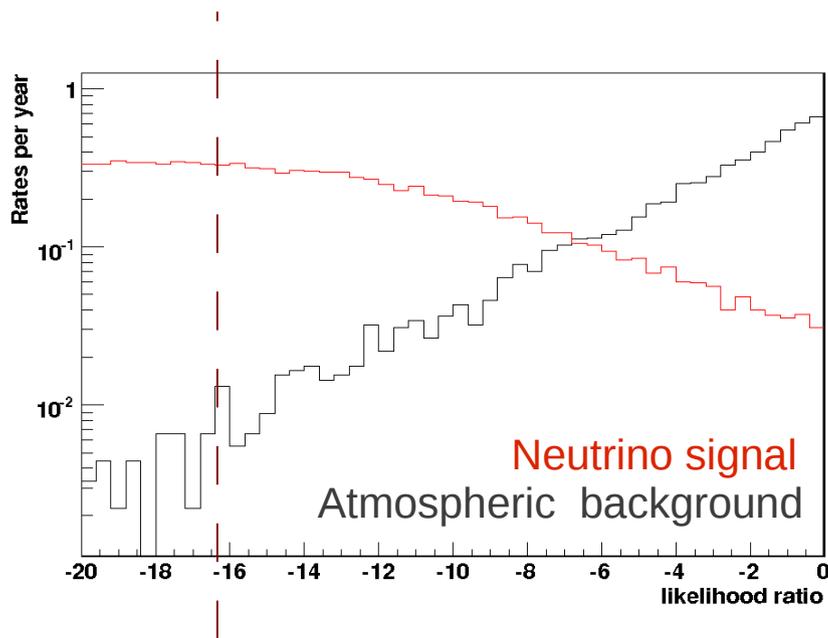

$$LLHR = \frac{P(\text{nohit}|\text{external})}{P(\text{nohit}|\text{internal})}$$

$$R = \sqrt{(X_{\text{vertex}} - 46\text{m})^2 + (Y_{\text{vertex}} + 34.5\text{m})^2} .$$

Atmospheric Muon Veto L2 Cuts: Optimization for Point Source search

Reject the maximum number of atmospheric muon background while keeping the maximum number of signal events starting inside IceCube-DeepCore.

$R < 180\text{m}$, $Z < -210$ and $LLHR < -16$

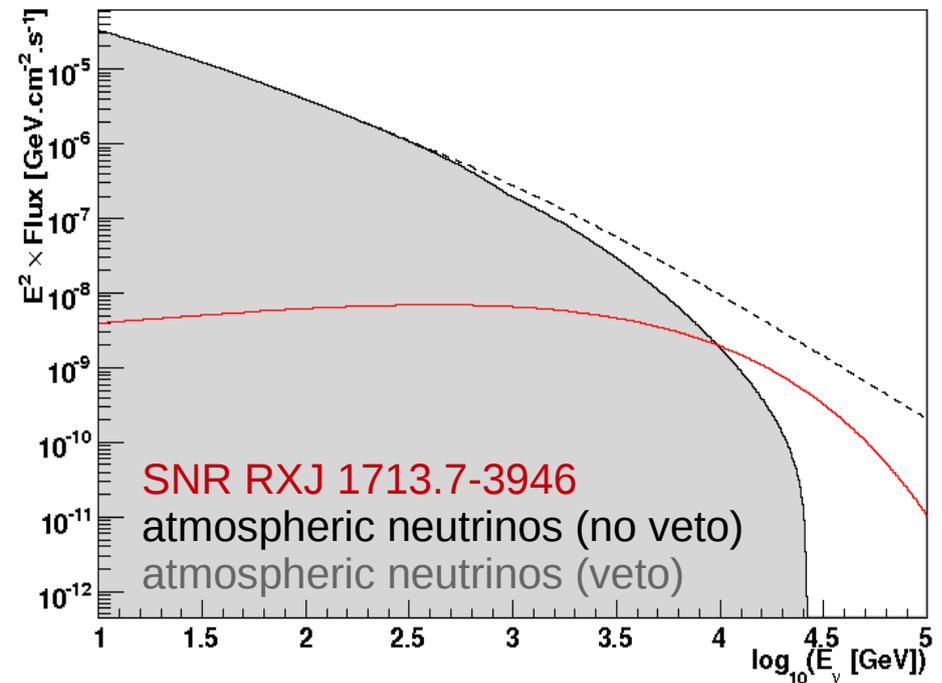

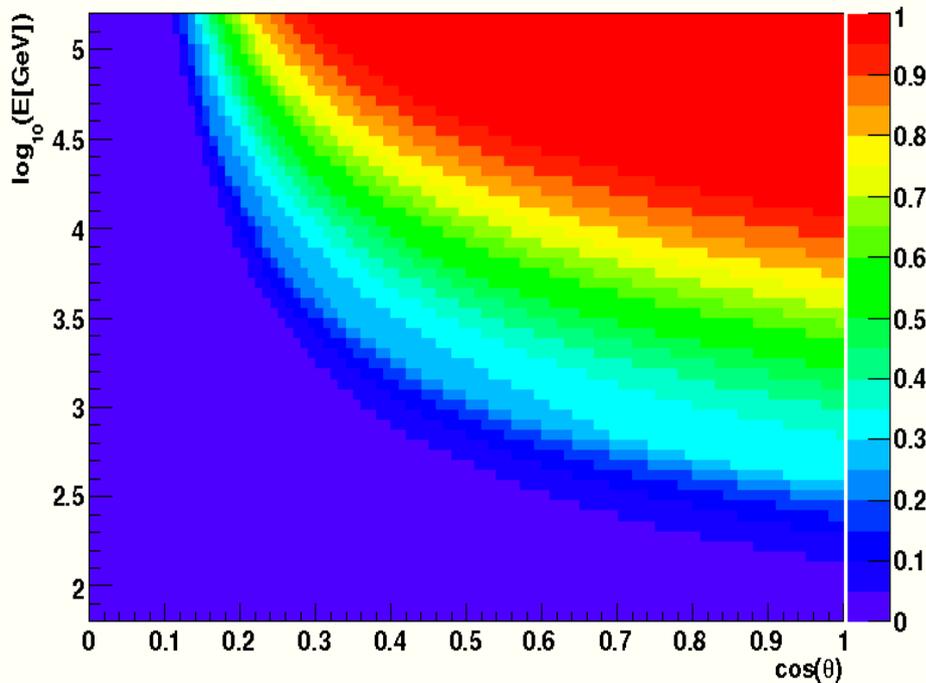

Background rejection: 10^{-6}
Signal passing rate: $\sim 50\%$

$$\text{Purity} = \frac{\text{Signal}}{\text{Signal} + \text{Atmospheric muon background}} > 98\%$$

Atmospheric neutrino veto

Phys.Rev.D79,043009 (2009) [astro-ph]: 0812.4308, S.Schonert et al.

- At **Tev-PeV energies**, the opening angle between a downward-going atmospheric ν_μ and the μ produced by the decay of the same parent meson in the atmosphere is very small.
 - a downward-going atmospheric ν_μ has a **certain probability** to reach the detector accompanied by its partner μ .
 - veto a downward-going atmospheric ν_μ by the detection of a correlated atmospheric μ .
- The veto performances depend on the **atmospheric muon veto** efficiency, the **depth** of the telescope and on the **neutrino energy** and **direction**.

Point-source analysis: SNR RXJ 1713.7-3946

- Monte Carlo simulations with **IceCube 80-strings** and **DeepCore 6-strings** configurations.
- Keep events in a **zenith band of width 10°** around the source.
 - Signal: Muon-neutrinos starting inside DeepCore (IceCube Neutrino Generator): *2800 events*.
 - Background: atmospheric muons (CORSIKA) *< 2 events*.
atmospheric neutrinos (*conventional flux, HONDA 2006*) *< 2250 events*.
 - Signal events are distributed according to:

$$\frac{dN}{dE_\nu} = 15.52 \times \left(\frac{E_\nu}{1 \text{ TeV}} \right)^{-1.72} e^{-\sqrt{\frac{E_\nu}{1.35}}} 10^{-12} \text{ TeV}^{-1} \cdot \text{cm}^{-2} \cdot \text{s}^{-1} .$$

Source PDF:

$$S_i = \frac{1}{2\pi\sigma^2} e^{-\frac{|\vec{x}_i - \vec{x}_s|}{2\sigma^2}}$$

Track reconstruction algorithms are under development:

Approximated angular resolution of DeepCore:

$\sigma = 2^\circ$ (*consistent with preliminary results from reconstruction*)

Neutrino energies considered: **$100 \text{ GeV} < E_\nu < 1 \text{ PeV}$** .

Unbinned Likelihood Ratio method

J. Braun et al., *Astropart.Phys.*29:299-305 (2008)

- The events are given a probability to belong to the source with a certain uncertainty σ .

$$S_i = \frac{1}{2\pi\sigma^2} e^{-\frac{|\vec{x}_i - \vec{x}_s|}{2\sigma^2}}$$

Source PDF with σ : DeepCore angular resolution (2°)

- The probability for an event to be an atmospheric background event is given by:

$$B_i = \frac{1}{\omega_{band}}$$

Background PDF with ω : solid angle of the zenith band.

- The **Likelihood** for a source to be at location X_s with a strength N_s is therefore:

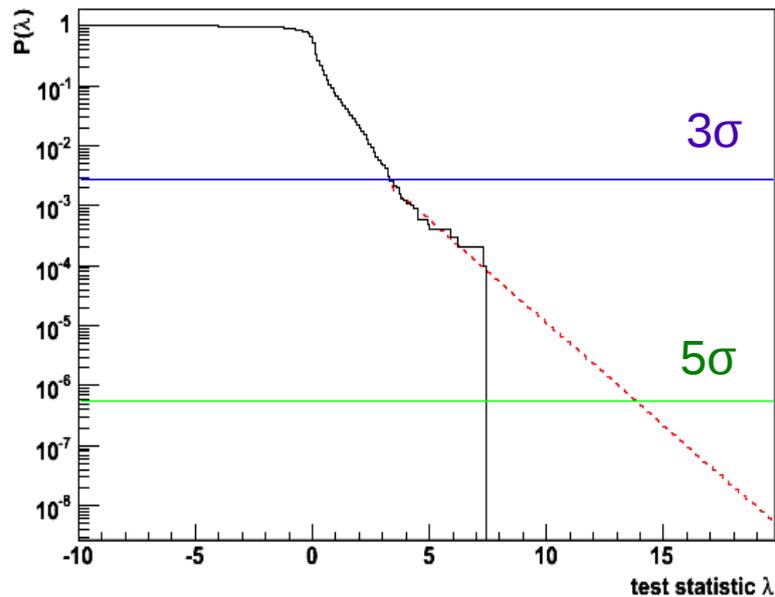

$$L = \prod_N \frac{N_s}{N} S_i + \left(1 - \frac{N_s}{N}\right) B_i$$

N: total number of events
(signal + background)

- The likelihood L is maximized to obtain the best estimate of the number of signal events.

Test Statistic & Significance

- The events are Poisson-distributed around a mean source strength: $\langle N_s \rangle = [-10; 40]$ events.
→ Scale the flux model by a factor **FLUXSCALE**.
- Signal + Background simulation: **1000** experiments for each **FLUXSCALE**.
- Background alone: **10000** experiments with randomized azimuth.
- For each experiment we record the **test statistic λ** to determine the significance of a deviation from the null hypothesis H_0 :

$$\lambda_{3\sigma} = 3.4 \quad \lambda_{5\sigma} = 13.9$$

$$\lambda = -2 \cdot \text{sign}(\hat{N}_s) \cdot \log \frac{L(\vec{X}_s, 0)}{L(\vec{X}_s, \hat{N}_s)}$$

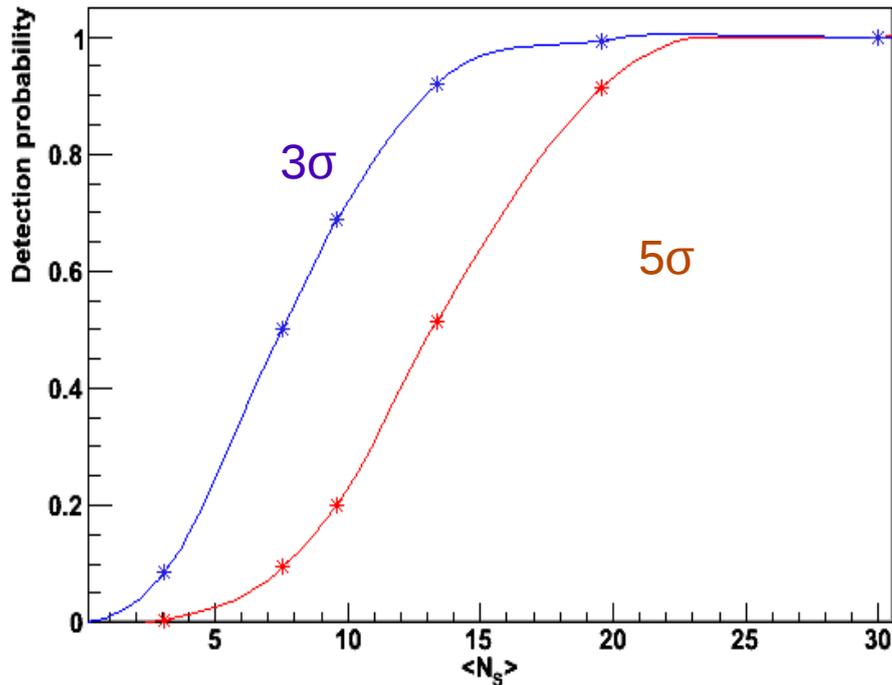

$H_0 = L(\vec{X}_s, 0)$: The data consists of background events.

$H_s = L(\vec{X}_s, \hat{N}_s)$: The data consists of \hat{N}_s signal events from the source and background events.

The **discovery potential at 3σ and 5σ** are the number of experiments with λ above the 3σ and 5σ threshold, respectively.

Discovery Fluxes: SNR RXJ 1713.7-3946

- 3σ and 5σ confidence level **detection probability** vs. Poisson mean number of source signal events (atmospheric muon background rejection: 10^{-6}).

Number of signal events needed on top of the background to achieve a **50% chance of detection** at the 3σ and 5σ C.L.:

$$\left\{ \begin{array}{l} \bar{\mu}(50\%, 3\sigma) = 7.656 \text{ events} \\ \bar{\mu}(50\%, 5\sigma) = 13.17 \text{ events} \end{array} \right.$$

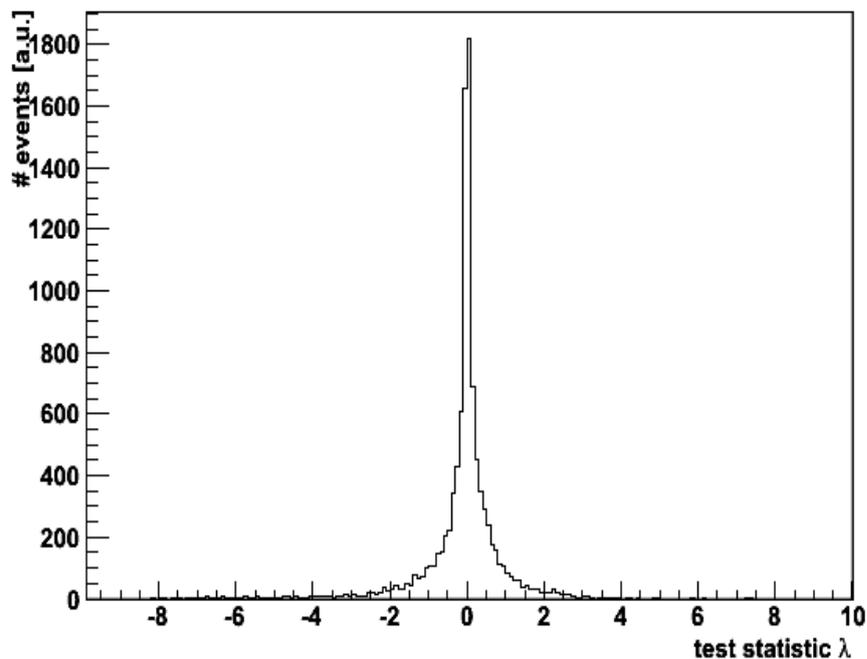

DISCOVERY FLUXES (after one year):

$$\Phi_{50\%, 3\sigma} \leq 4.00 \times 15.52 \times E^{-1.72} \times e^{-\sqrt{E/1.35}} \times 10^{-10} \text{ TeV}^{-1} \cdot \text{cm}^{-2} \cdot \text{s}^{-1}$$

$$\Phi_{50\%, 5\sigma} \leq 6.96 \times 15.52 \times E^{-1.72} \times e^{-\sqrt{E/1.35}} \times 10^{-10} \text{ TeV}^{-1} \cdot \text{cm}^{-2} \cdot \text{s}^{-1}$$

Sensitivity to SNR RXJ 1713.7-3946

Neyman 90% C.L. Upper Limit (*Amsler et al. 2008*)

Distribution of λ for background alone

$$\lambda_{\text{Median}} \sim 0.00$$

$$\mu_{90\%} = 5.86 \text{ events}$$

Neyman-Pearson lemma:

$$\text{Reject } H_0 \text{ if } P(\lambda > \lambda_{\text{Median}} | H_0) = 90\%$$

H_0 – Null hypothesis.

The data consists only of background

H_1 – The data consists of signal and background.

Sensitivity at the 90% C.L (after one year):

$$\phi_{90\%} \leq 2.84 \times 15.52 \times E^{-1.72} \times e^{-\sqrt{E}/1.35} \times 10^{-10} \text{ TeV}^{-1} \cdot \text{cm}^{-2} \cdot \text{s}^{-1}$$

Enhancement of the Sensitivity (after one year, at the 90% C.L.)

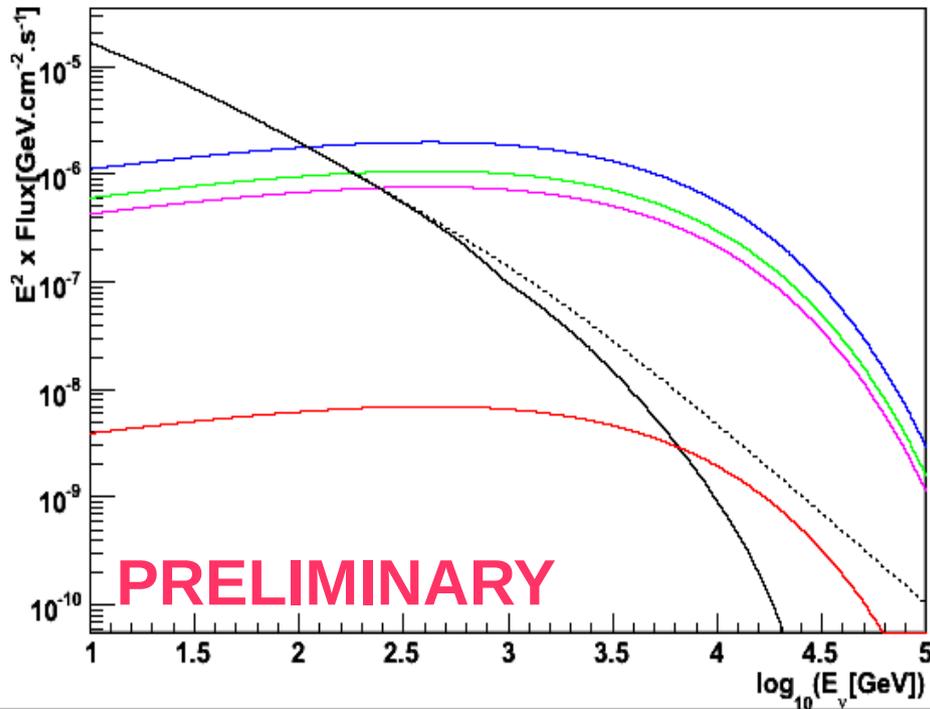

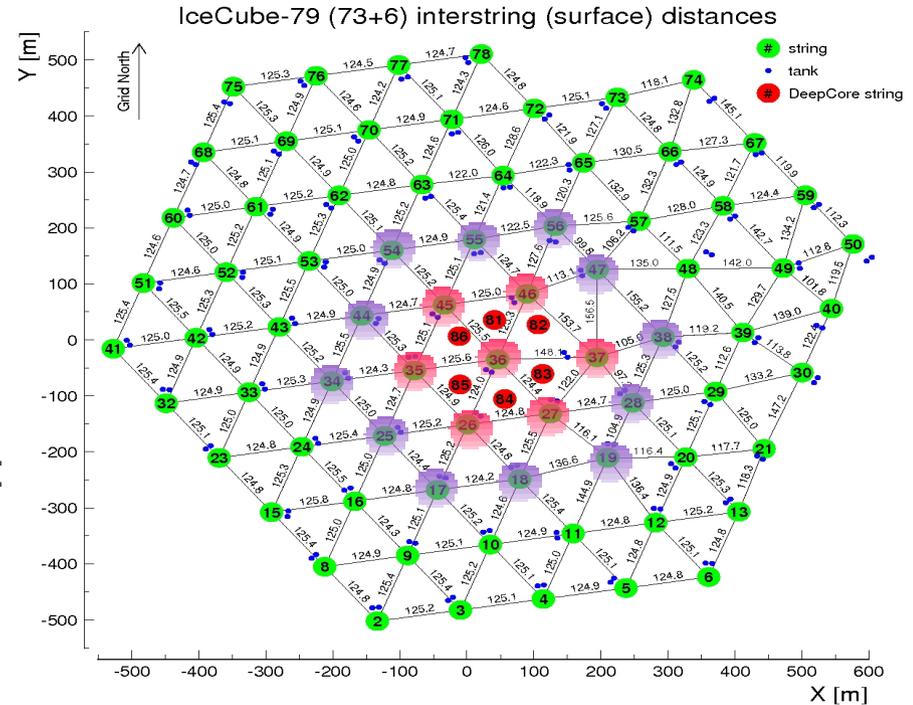

(1) → (2): Relaxation of the μ_{Atmo} Veto cuts:

$\left\{ \begin{array}{l} \text{Background rejection of } 10^{-5} \\ \text{Passing rate of starting neutrinos: 85\%} \end{array} \right.$

→ Sensitivity enhanced by a **factor of ~ 2.**

(2) → (3): Increase horizontally the Fiducial Volume:

→ Sensitivity enhanced by a **factor of ~1.5.**

(1) $\phi_{90\%} \leq 2.84 \times 15.52 \times E^{-1.72} \times e^{-\sqrt{E/1.35}} \times 10^{-10}$

(2) $\phi_{90\%} \leq 1.53 \times 15.52 \times E^{-1.72} \times e^{-\sqrt{E/1.35}} \times 10^{-10}$

(3) $\phi_{90\%} \leq 1.09 \times 15.52 \times E^{-1.72} \times e^{-\sqrt{E/1.35}} \times 10^{-10}$

— expected signal flux

- - - atmospheric neutrino flux (no veto)

— atmospheric neutrino flux

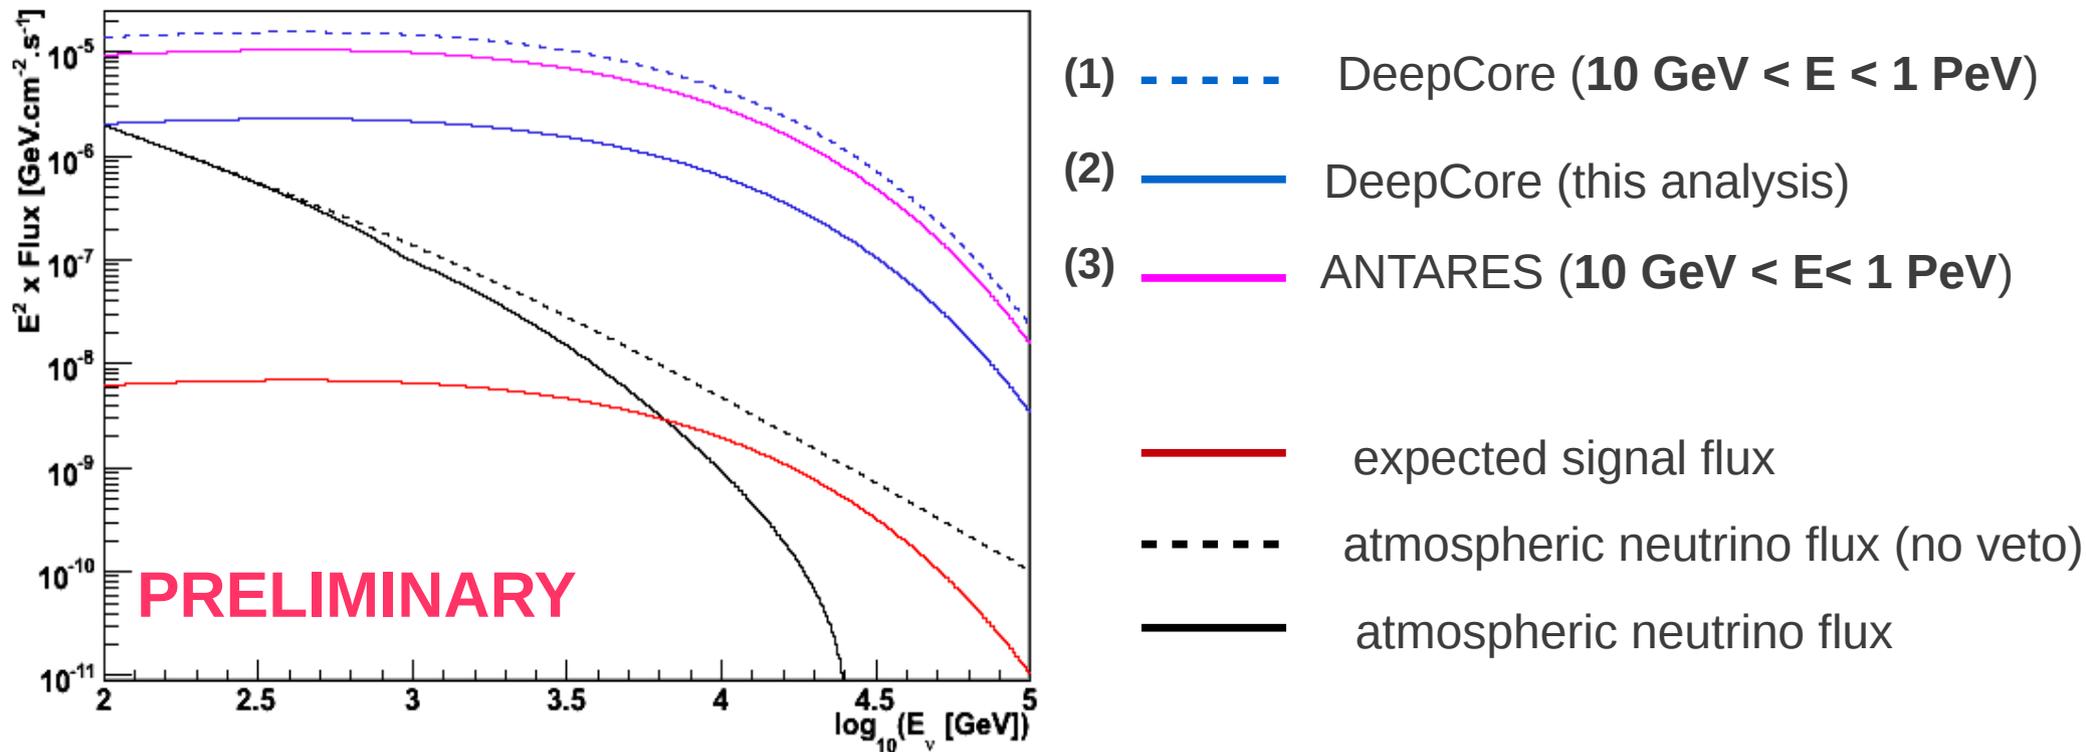

Comparison ANTARES vs IceCube-DeepCore Discovery Potential at 5σ

Calculations for ANTARES have been made by A. Kappes (from [\[astro-ph\]arXiv:0607286](#)):

- Use of an ANTARES old effective area which is not zenith dependent (*Brunner et al., 2005*)
- It is assumed that all atmospheric muons can be suppressed.
- Assumed angular resolution: 0.4° for energies between **10 GeV and 1 PeV**.

Discovery potential of ANTARES to the SNR RXJ 1713.7-3946 (after 1 year):

$$\phi_{50\%, 5\sigma} \leq 15 \times 15.52 \times E^{-1.72} \times e^{-\sqrt{E/1.35}} \times 10^{-10} \text{ TeV}^{-1} \cdot \text{cm}^{-2} \cdot \text{s}^{-1}$$

CONCLUSIONS and OUTLOOK

- An **innovative** and **exploratory approach** to Neutrino Astronomy is under development to observe steady soft/hard-spectra **galactic neutrino sources**.
- A **very preliminary** sensitivity to the **benchmark source *RXJ 1713.7-3946*** has been presented.
- The **atmospheric muon veto** and **IceCube-DeepCore** can be used to open the field of view of IceCube to the Southern Hemisphere below 1 PeV.
- The **atmospheric neutrino veto** can be used to discriminate part of the source signal (depending on the source location and the neutrino energy) from the background of atmospheric Neutrinos.
- By using **DeepCore as an active veto** (against atmospheric muons and neutrinos) the discovery potential/sensitivity of DeepCore to the SNR *RXJ 1713.7-3946* **becomes comparable** with the discovery potential/sensitivity of ANTARES.

NEXT STEPS

- Develop dedicated **simulations** (based on CORSIKA) to assess the **atmospheric neutrino veto** capability in practice.
- Study the impact of the atmospheric neutrino veto on the discovery potential/sensitivity as a function of the energy.
- Include muon track and energy **reconstruction algorithms**.
 - Determine IceCube-DeepCore angular resolution as a function of the energy.
- Include **energy term in the likelihood** maximization (expected improvement of about **30%**) as described in ***J.Braun et al., Astroparticle Physics 29 (2008) 299-305***
- Estimate the sensitivity to **other astrophysical objects of interest** (H.E.S.S. SNRs, Galactic Center region) throughout the Southern Hemisphere.
- Investigate **potential extensions of *IceCube-DeepCore*** to enhance the sensitivity.
- **Analysis of the first data** from the 79 strings configuration of IceCube-DeepCore (Spring 2011).
- Investigate new strategies to **combine the data recorded by ANTARES and DeepCore**

Thank you!

EXTRA SLIDES

Test Statistic

- The events are Poisson-distributed around a mean source strength: $\langle N_s \rangle = 0 - 40$ events.

→ Scale the flux model by a factor **FLUXSCALE**.

- Downward fluctuations of the background:

$$-10 < N_s < 40$$

- Signal + Background simulation: **1000** experiments for each **FLUXSCALE**.

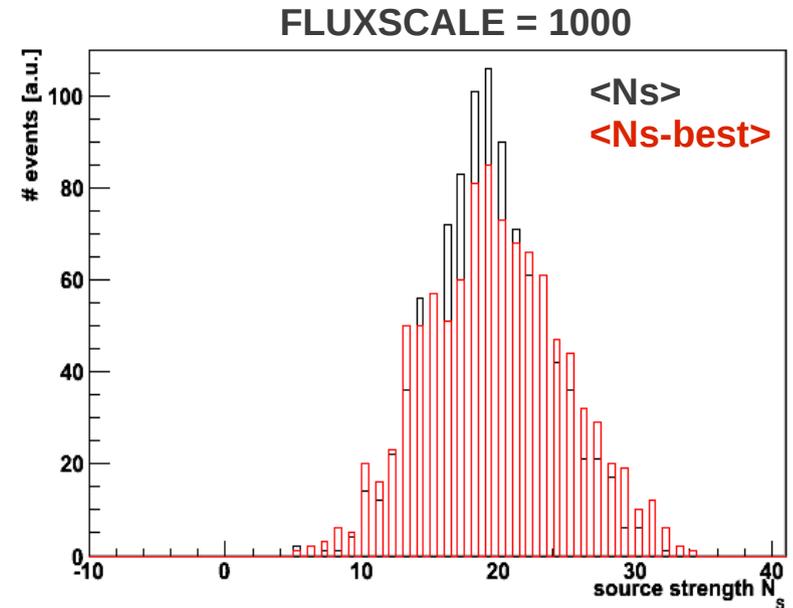

- Background alone: **10000** experiments with randomized azimuth.

- For each experiment we record the **test statistic** λ to determine the **significance** of an observed deviation from the null hypothesis.

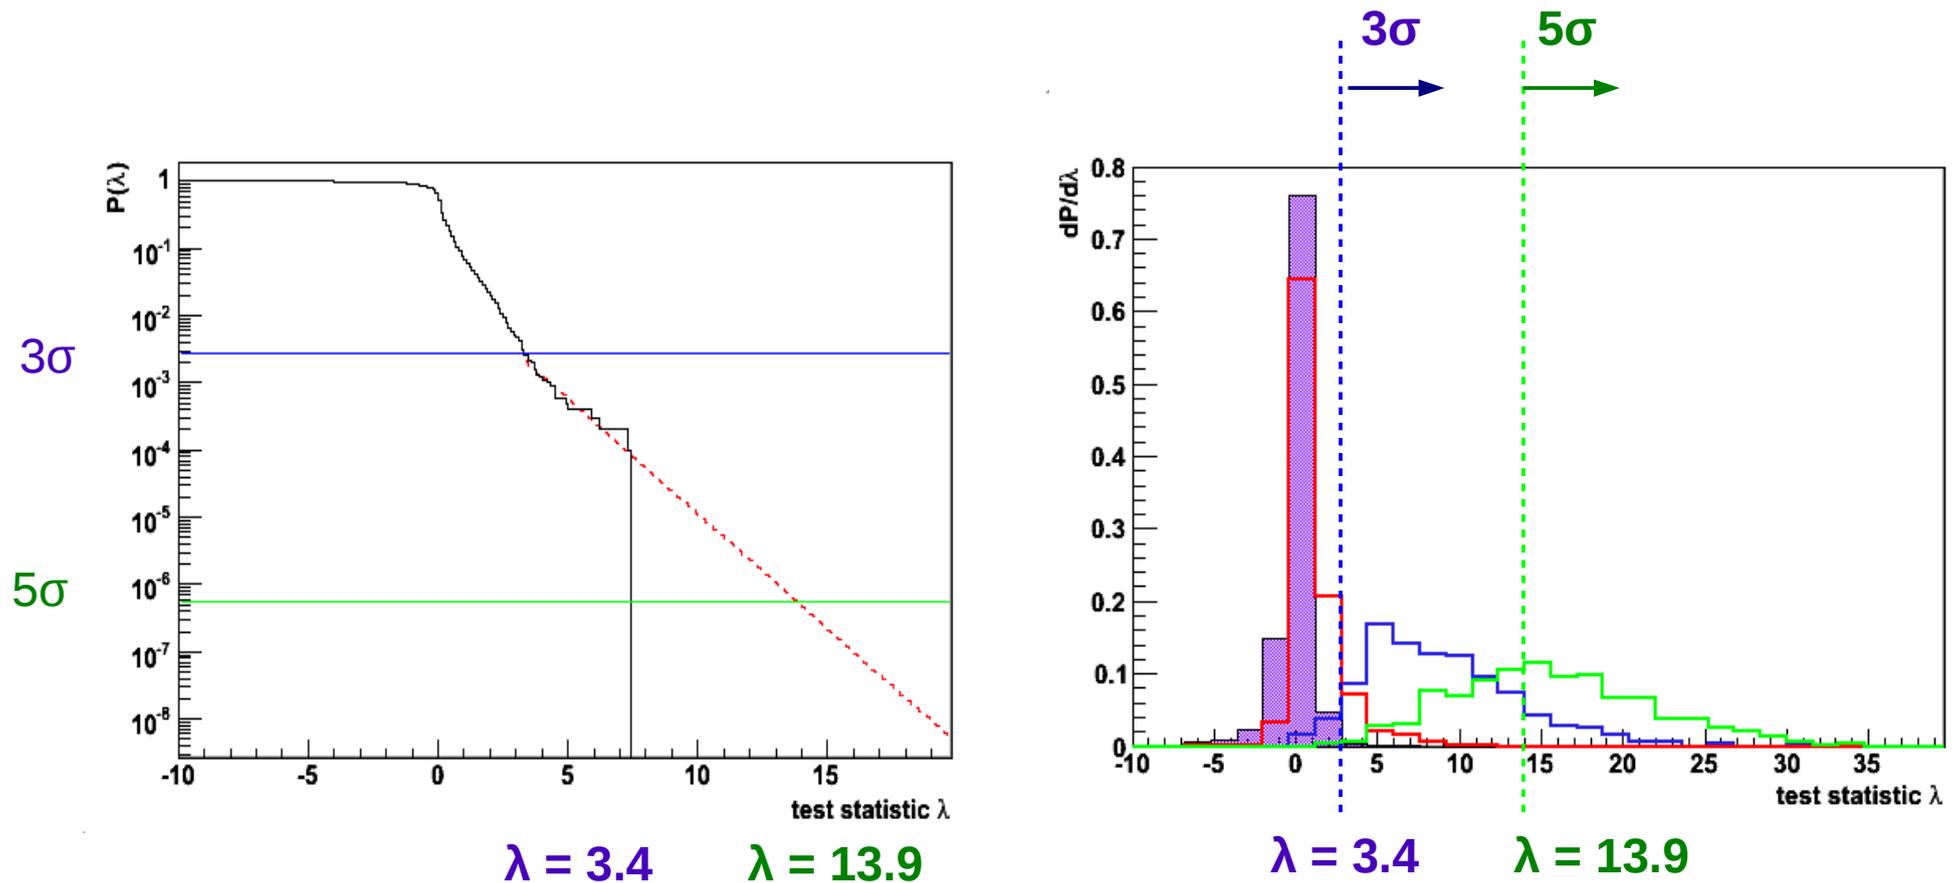

$$\lambda = -2 \cdot \text{sign}(\hat{N}_s) \cdot \log \frac{L(\vec{X}_s, 0)}{L(\vec{X}_s, \hat{N}_s)}$$

$H_0 = L(\vec{X}_s, 0)$ The data consists only of background events.

$H_s = L(\vec{X}_s, \hat{N}_s)$ The data consists of \hat{N}_s signal events from the source and background events.

Significance and discovery potential Procedure

- The integral distribution of λ for the background alone is calculated at the location of the source.
- The values of λ corresponding to 3σ and 5σ are calculated.
- The discovery potential at 3σ and 5σ are the number of experiments with λ above the 3σ and 5σ threshold, respectively.

PROPOSAL

Combined analysis: IceCube-DeepCore and ANTARES.

Opening the field of view of **IceCube** to the Southern Hemisphere allows an overlap with **neutrino telescopes of the Northern Hemisphere.**

→ Investigate new strategies for combining the data collected by **IceCube-DeepCore** and **ANTARES.**

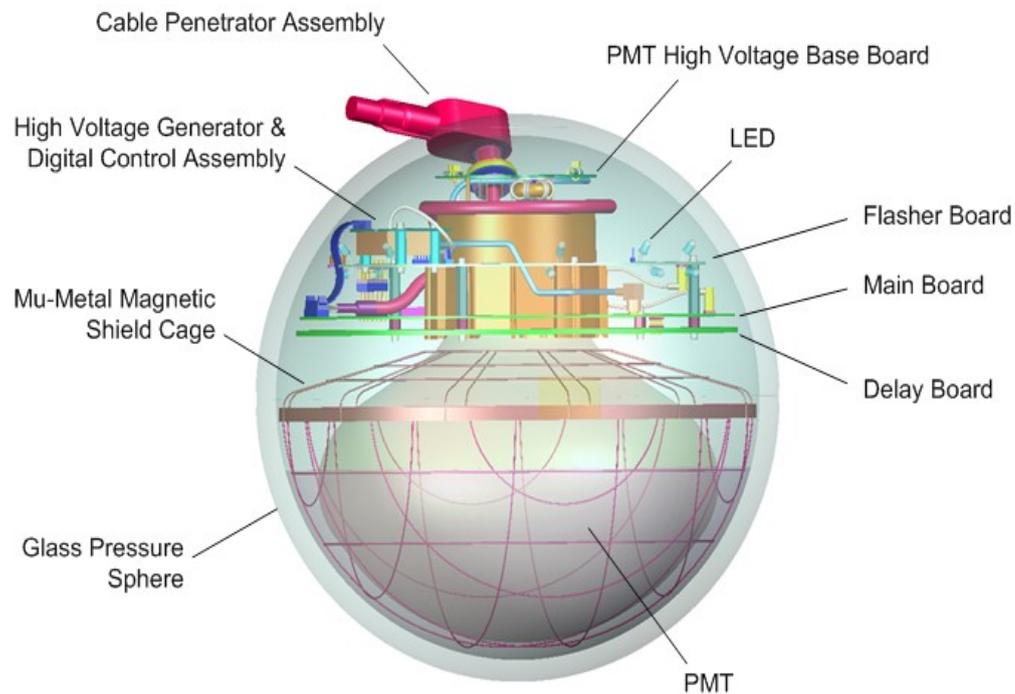

Motivations:

- **Enhance the sensitivity** to the signal coming from soft-spectra Galactic Neutrino Sources.
- The systematic errors involved in both telescopes differ, in particular due to the different media in which they are deployed.
 - By combining both telescopes such **systematics could be avoided** or at least consequently reduced.
