CMS cross section

CMS: One of 2 general-purpose experiments intended for data-taking on 7 TeV pp collisions at the LHC

5 layers of subdetectors across more than 7 meters from the beam spot, of which we are most concerned with the silicon tracker and calorimeters.

Rutgers

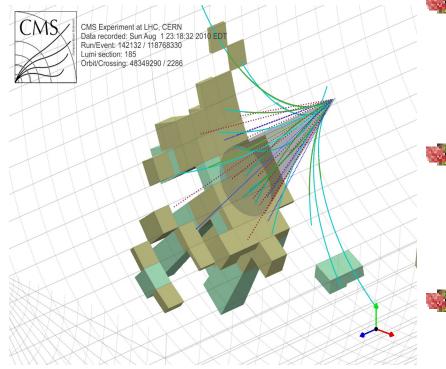

- Jets are seen in abundance at high energy colliders. As a result, QCD predictions are among the first that can be explored and validated at the new energy frontiers of the LHC
- Measurements such as the Inclusive Jet and Dijet Mass cross-section are important standard candles as well, for individual experiments
- Constrains theoretical predictions
- Validates generators used by nearly all analysis groups
- A wide variety of new physics shows up as a resonance "bump" or some other distortion

Jets at CMS

PF Jet (with calorimeter deposits) in CMS

All algorithms in these measurements use anti-k₊ clustering to produce jets

- Seedless + Infra-red Safe
- Default for most analyses requiring jets
- 3 reconstruction algorithms:
 - Calorimeter Jets
 - Jets + Tracks
 - Particle Flow (PF) Jets
- Particle Flow takes individual particle candidates and creates jets/MET
 - Best resolution and lowest Jet Energy Scale uncertainty (our highest experimental uncertainty)

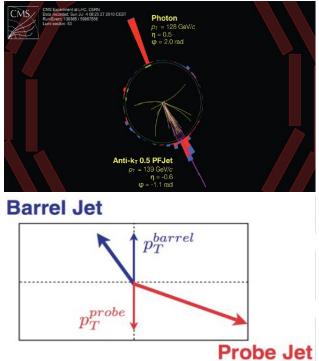

Jet Energy Scale

Due to the sharply falling nature of both cross-sections in p_T/M_{jj}, the greatest contribution to the systematic uncertainty of both measurements is inaccuracy in the Jet Energy Scale.

Absolute p_T **correction** – The absolute scale for jets is determined by balancing photon + jet events. PF algorithm ensures that we measure the full recoil with minimal systematic error.

Relative p_{T} **correction** - Taking dijet events, balance the p_{T} of a jet in the barrel with that of a jet at arbitrary η . (Tag-andprobe)

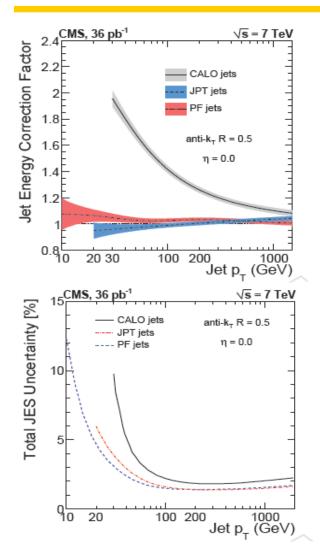

The corrected jets are then compared to MC distributions and an additional residual correction is applied to achieve closure.

Rutgers

Jet Energy Corrections

Our corrective factors for the jet response for these measurements were derived on the full 36 pb^{-1} in 2010.

Again, due to the improved response for charged particles via tracking information, JPT and PF Jets require lesser corrections than CaloJets.

The end result is an overall JES uncertainty of 2-5% for the entirety of the phase space considered, allowing a precision measurement to be made

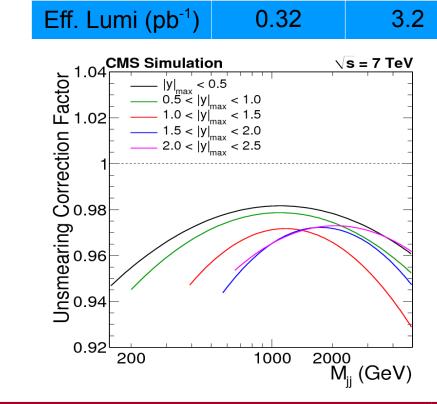

CMS approved result: JME-10-011 See talk: "Jet Energy Calibration and Transverse Momentum Resolution in CMS" (I. lashvili)

Spectrum Construction

The events used in both measurements are selected using a series of triggers that fire on the uncorrected p_{T} of the leading jet. We then construct the spectra in p_{T}/M_{jj} (after corrections) in regions in which the individual triggers are 100% efficient.

| Trigger | Jet30 | Jet50 | Jet70 | Jet100 | Jet140 |
|-------------------------------|-------|-------|-------|--------|--------|
| Eff. Lumi (pb ⁻¹) | 0.32 | 3.2 | 8.6 | 19 | 36 |

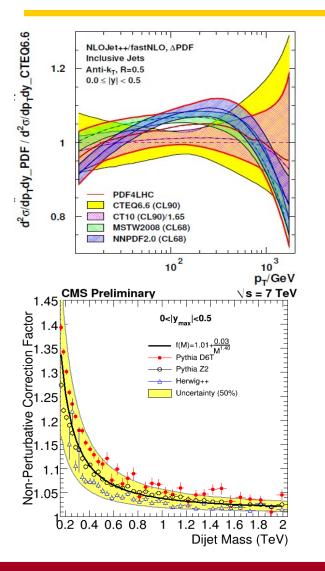

The comparison to theory is performed at particle level. We correct the detector level information back by applying the *ansatz* unfolding method.

The p_T/M_{jj} response is smeared by an estimation of the detector resolution and an "unsmearing" correction is derived bin-by-bin for both measurements.

Comparison to Theory

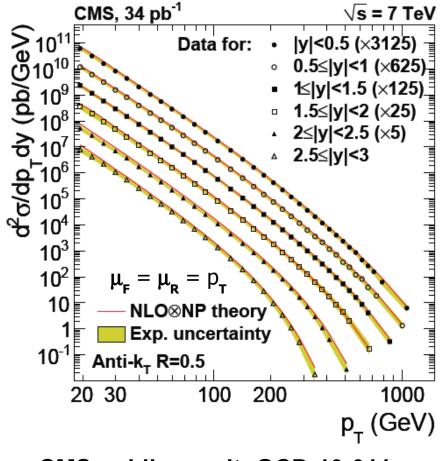

- Variety of PDFs considered using the PDF4LHC method – prescription for general comparison of these measurements to theory
 - Prediction from each PDF is calculated with 1σ uncertainty
 - The center of the global area within these bands is the PDF4LHC prediction
- Generated using NLOJet++

- Non-perturbative corrections applied to bring partonlevel calculations to particle-level
 - Corrections to NLO acquired by turning MPI and hadronization on/off in MC
 - Result averaged from Pythia6 and Herwig++

Rutgers Inclusive Jet Cross-section

CMS public result: QCD-10-011 arXiv:1106.0208v1 [hep-ex]

$$\frac{\mathrm{d}^2 \sigma}{\mathrm{d} p_T \mathrm{d} |y|} = \frac{C_{\mathrm{unsm}}}{\epsilon \cdot \mathcal{L}} \cdot \frac{N_{\mathrm{jets}}}{\Delta p_T \Delta |y|}$$

- The cross section
 measurement extends
 from 18 GeV to 1.1 TeV
 in jet p_T
- Good agreement with NLO theory predictions over 10 orders of magnitude in 6 rapidity bins

Inclusive Jets vs. NLO

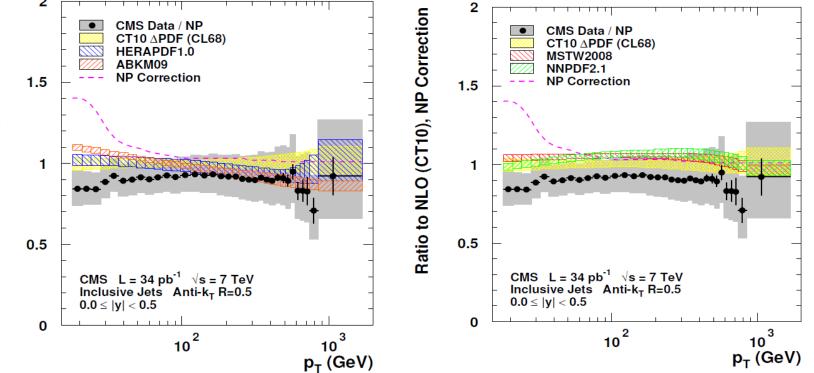

Additional cross-check with CaloJets shows consistency between algorithms

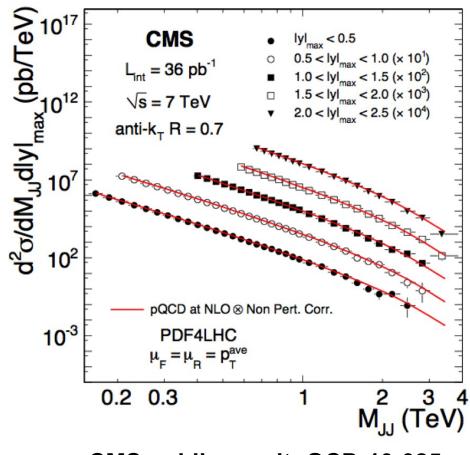

Additional comparisons have been performed against a variety of PDFs for consistency, using CT10 as a baseline. This is the next step in comparing the validity of various theoretical predictions.

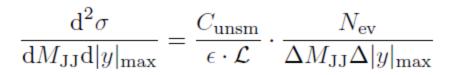

The data remains consistent with respect to CT10 in the areas of interest for this measurement

Rutgers Dijet mass differential cross-section

CMS public result: QCD-10-025 arxiv:1104.1693v1 [hep-ex]

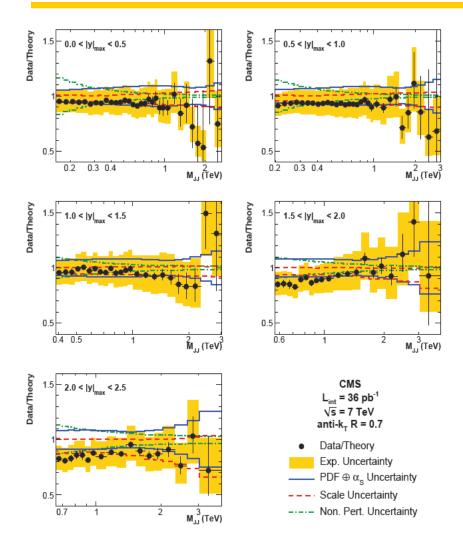

Dijet event selection requires: $p_{T(jet1)} > 60 \text{ GeV}, p_{T(jet2)} > 30 \text{ GeV}$

Measurement uses larger cone size to remain consistent with previous dijet searches and reduce sensitivity to out-of-cone effects

Final result: cross-section measurement with reach from 160 GeV to 3.5 TeV in $M_{_{\rm II}}$

Rutgers Dijet Mass Cross-section ratio

- Similar to the Inclusive Jet measurement, theory uncerainty is dominated by NP corrections at low mass and PDFs at high mass
- Measurement also trends low,
 but nonetheless shows good agreement with theory within uncertainties in all regions

2

M_{.L} (TeV) M_{.11} (TeV) The same NLO comparisons to individual PDFs have been produced for the Dijet mass measurement. The spectra show agreement with most PDFs to a high degree.

2

Summary

- Dijet mass and Inclusive Jet cross-sections produced on the full 2010 dataset at CMS, and continue to be monitored as we cross 1 fb⁻¹ in 2011
- Both results are, at this early stage, still in good agreement with NLO QCD predictions
 - Trending low, but still within uncertainties
- A wide variety of searches are primed to take advantage of these critical measurements as we continue taking data in 2011
