Viscosity in N=4 SYM

Limitations

Summary

Asymptotic freedom

- Running coupling : $\alpha_s = g^2/4\pi$

$$\alpha_s(r) = \frac{2\pi N_c}{(11N_c - 2N_f) \log(1/r\Lambda_{QCD})}$$

Partition function

Lattice QCD

AdS/CFT

Gauge-gravity duality

Viscosity in N=4 SYM

Limitations

Summary

- The quark potential increases linearly with distance

- In nature, we do not see free quarks and gluons (the closest we have to actual quarks and gluons are jets)
- Instead, we see hadrons (quark-gluon bound states):

- The hadron spectrum is uniquely given by $\Lambda_{\text{QCD}}, m_f$
- But this dependence is non-perturbative (it can now be obtained fairly accurately by lattice simulations)

Perturbative QCD

Lattice QCD

Partition function

Lattice QCD

AdS/CFT

Gauge-gravity duality

Viscosity in N=4 SYM

Limitations

Summary

- In a dense medium, color charges are screened by their neighbors
- The interaction potential decreases exponentially beyond the **Debye radius** r_{debye}
- Hadrons whose radius is larger than r_{debye} cannot bind

- In lattice calculations, one sees the $q\bar{q}$ potential flatten at long distance as T increases

Why small-x gluons matter

Gluon saturation

Perturbative QCD

Lattice QCD

Partition function

Lattice QCD

AdS/CFT

Gauge-gravity duality

Viscosity in $N=4$ SYM

Limitations

Summary

- Rapid increase of the pressure :
 - at $T \sim 270$ MeV, with gluons only
 - at $T \sim 150$ to 180 MeV, with light quarks
- ▷ interpreted as the increase in the number of degrees of freedom due to the liberation of quarks and gluons

- Viscosity in N=4 SYM
- Limitations

Summary

What we must get out of the way first...

- Unfortunately, heavy ion collisions also depend on a number of other trivial facts:

- i. Lead nuclei are approximately spherical
- ii. Their diameter is about 12 fermis
- iii. They contain $A \approx 200$ nucleons
- iv. The positions of these nucleons fluctuate

- These properties have all an incidence on observables
- None of them is interesting from the point of view of QCD
- We need ways to make observables independent of these trivial aspects of nuclear physics

Lattice QCD

AdS/CFT

Gauge-gravity duality

Viscosity in N=4 SYM

Limitations

Summary

- Except for the production of hard objects (jets, heavy quarks, direct photons) at the impact of the two nuclei, we have to deal with strong interactions in a non-perturbative regime
NOTE: non-perturbative \neq strongly coupled!!!
- Treated with a range of effective descriptions (**semi-classical methods**, **hydrodynamics**, **kinetic theory**) that are more or less closely related to QCD, but always require some QCD input

The multiple facets of QCD in Heavy Ion Collisions

- The simple formulation of QCD is deceptive: Ab initio calculations are very difficult, and feasible only for a handful of questions
- In many instances, it is more efficient to use an effective theory in which inessential degrees of freedom have been integrated out

Lattice QCD

AdS/CFT

Gauge-gravity duality

Viscosity in N=4 SYM

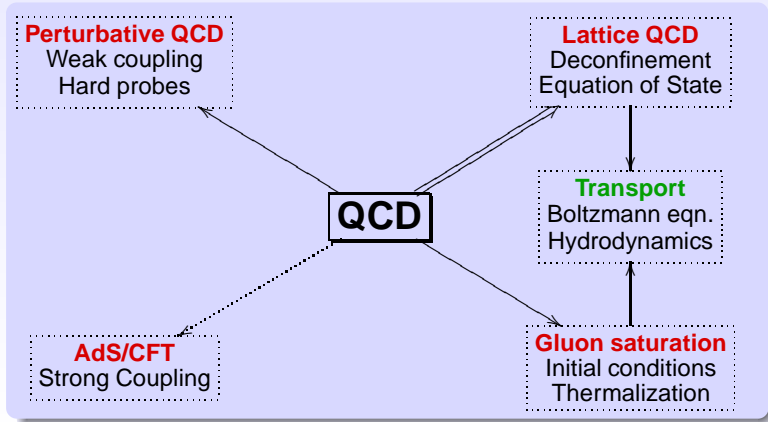

Limitations

Summary

- In many cases, the description of the system can be done at a scale large enough for the microscopic details to become irrelevant:
 - Kinetic theory
 - Hydrodynamics
- To a large extent, the evolution of the system is driven by conservation laws (energy, momentum, baryon number...)
- The microscopic dynamics is relegated into a handful of quantities that enter in these mesoscopic descriptions

Why small-x gluons matter

Gluon saturation

Perturbative QCD

Lattice QCD

Partition function

Lattice QCD

AdS/CFT

Gauge-gravity duality

Viscosity in N=4 SYM

Limitations

Summary

- The system is described by a particle distribution

$$f(t, \vec{x}, \vec{p}) = \frac{dN}{d^3\vec{x}d^3\vec{p}}$$

(in most cases, this distribution is spin and color averaged)

- The evolution of f is driven by the interactions between these particles
- The only QCD input is a set of cross-sections

AdS/CFT

Gauge-gravity duality

Viscosity in N=4 SYM

Limitations

Summary

Boltzmann equation

- The Boltzmann equation describes the evolution of a distribution of particles that undergo short range collisions

$$\left[\partial_t + \vec{v}_p \cdot \vec{\nabla}_x \right] f(t, \vec{x}, \vec{p}) = \underbrace{C_p[f]}_{\text{collisions}} \quad \text{with } \vec{v}_p \equiv \frac{\vec{p}}{E_p}$$

- Elementary 2-body collision :

Boltzmann equation

- For $2 \rightarrow 2$ collisions, the collision term reads :

$$\begin{aligned}
 \mathcal{C}_p[f] = & \frac{1}{2E_p} \int \frac{d^3\vec{p}'}{(2\pi)^3 2E_{p'}} \int \frac{d^3\vec{k}}{(2\pi)^3 2E_k} \int \frac{d^3\vec{k}'}{(2\pi)^3 2E_{k'}} \underbrace{(2\pi)^4 \delta(p+k-p'-k')}_{E, \vec{p} \text{ conservation}} \\
 & \times \left[\underbrace{f(\vec{p}')f(\vec{k}')(1+f(\vec{p}))(1+f(\vec{k})) - f(\vec{p})f(\vec{k})(1+f(\vec{k}'))(1+f(\vec{p}'))}_{\text{micro-reversibility, detailed balance}} \right] \underbrace{|\mathcal{M}|^2}_{\text{QCD}}
 \end{aligned}$$

▷ Most of the equation relies on conservation laws and general principles of statistical physics. Only the cross-section depends on QCD

Inputs

- i. Cross-sections
- ii. Initial condition $f(t_0, \vec{x}, \vec{p})$

Summary

Equations of hydrodynamics (conservation laws)

$$\partial_\mu T^{\mu\nu} = 0 \quad , \quad \partial_\mu J_B^\mu = 0$$

Assumptions and inputs

i. Near equilibrium form of $T^{\mu\nu}$:

$$T^{\mu\nu} = \underbrace{(p + \epsilon) v^\mu v^\nu - p g^{\mu\nu}}_{\text{ideal hydro}} \oplus \underbrace{(\eta, \zeta) \partial v}_{\text{viscous terms}} \oplus \dots$$

ii. Equation of State: $p = f(\epsilon)$

iii. Transport coefficients: η, ζ, \dots

iv. Initial condition for ϵ and \vec{v} at some t_0

Viscosity in $N=4$ SYM

Limitations

Summary

Longitudinal momentum fraction in AA collisions

- The partons that are relevant for the process under consideration carry the longitudinal momentum fractions:

$$x_{1,2} = \frac{P_{\perp}}{\sqrt{s}} e^{\pm Y}$$

- $P_{\perp} \sim 1 \text{ GeV}$
 - $x \sim 10^{-2}$ at RHIC ($\sqrt{s} = 200 \text{ GeV}$)
 - $x \sim 10^{-3}$ at the LHC ($\sqrt{s} = 2.76 \text{ TeV}$)
- ▷ partons at small x are the most important

Gauge-gravity duality

Viscosity in $N=4$ SYM

Limitations

Summary

Multiple scatterings and gluon recombination

- **Dense regime** : **multiparton processes** become crucial
 - ▷ gluon recombinations are important (**saturation**)
 - ▷ multi-parton distributions + JIMWLK evolution
 - ▷ new techniques are required (**Color Glass Condensate**):

$$\mathcal{L} = -\frac{1}{4}F^2 + \textcolor{violet}{J} \cdot \textcolor{red}{A}$$

(gluons only, field $\textcolor{red}{A}$ for $k^+ < \Lambda$, classical source $\textcolor{violet}{J}$ for $k^+ > \Lambda$)

Perturbative QCD

Lattice QCD

Partition function

Lattice QCD

AdS/CFT

Gauge-gravity duality

Viscosity in N=4 SYM

Limitations

Summary

- Power counting :
 - $J \sim g^{-1}$ in the saturated regime
 - Each g^2 order gets contributions from an infinite set of graphs
 - LO: all tree graphs, classical fields
 - NLO: one loop, small field fluctuations over a classical background
 - Applications :
 - Initial conditions for hydrodynamics
 - Study of thermalization
 - Main issue : the g^2 expansion is not uniform in time
 - ▷ secular divergences
- [▷ see T. Epelbaum's talk]

Perturbative QCD

Lattice QCD

Partition function
Lattice QCD

AdS/CFT

Gauge-gravity duality
Viscosity in N=4 SYM
Limitations

Summary

- The basis of perturbative QCD is asymptotic freedom
- pQCD is the tool of choice for computing the production of hard objects (high p_{\perp} jets, direct photons, heavy quarks)
- In heavy ion collisions, a new challenge for QCD is the study of the propagation of a hard object in a dense quark-gluon medium

Perturbative QCD

Lattice QCD

Partition function

Lattice QCD

AdS/CFT

Gauge-gravity duality

Viscosity in N=4 SYM

Limitations

Summary

- Partition function :

$$Z \equiv \text{Tr} (e^{-\beta H}) = \int [\mathcal{D}A^\mu \mathcal{D}\bar{\psi} \mathcal{D}\psi] e^{-S_E[A^\mu, \bar{\psi}, \psi]}$$

- S_E is the Euclidean action, with imaginary time in $[0, \beta = 1/T]$. The **Matsubara formalism** provides a way to do perturbative calculations at finite T

- Z knows everything about the QGP thermodynamics :

$$E = -\frac{\partial Z}{\partial \beta}$$

$$S = \beta E + \ln(Z)$$

$$F = E - TS = -\frac{1}{\beta} \ln(Z)$$

Perturbative QCD

Lattice QCD

Partition function

Lattice QCD

AdS/CFT

Gauge-gravity duality

Viscosity in N=4 SYM

Limitations

Summary

- **Lattice QCD** : discretize space-time, and approximate the functional integration by a Monte-Carlo sampling
- **“Sign problem”** :
 - does not work for “real time” correlation functions
 - ▷ limited to static properties of the QGP (thermodynamics)
 - does not work with a baryon chemical potential
- Light quarks with realistic masses are computationally expensive

Gauge-gravity duality

Viscosity in $N=4$ SYM

Limitations

Summary

Viscosity at weak coupling

- It all started with the observation that hydrodynamics reproduces well the data provided one uses a very small viscosity
- The shear viscosity has been calculated in QCD at weak coupling ($g \rightarrow 0$), and it is quite large :

$$\frac{\eta}{s} = \frac{5.12}{g^4 \ln\left(\frac{2.42}{g}\right)}$$

AdS/CFT

Gauge-gravity duality

Viscosity in N=4 SYM

Limitations

Summary

- Maximally super-symmetric $SU(N)$ Yang-Mills theories in the limit $g^2 N \rightarrow +\infty$ are dual to classical super-gravity on an $AdS_5 \times S_5$ manifold with metric

$$ds^2 = \frac{R^2}{z^2} (\underbrace{-dt^2 + d\vec{x}^2}_{\text{we live here... (at } z=0)}) + R^2 d\Omega_5^2$$

- If an operator \mathcal{O} of our world is coupled on the boundary to a field φ_0 that extends in the bulk, the duality states that :

$$e^{-S_{cl}[\phi]} = \langle e^{\int_{\text{boundary}} \mathcal{O} \varphi_0} \rangle$$

- The right hand side is a generating functional for the correlators of operators \mathcal{O} in the 4-dim gauge theory
- The left hand side is calculable in the gravity dual (solve the classical EOM for ϕ with the boundary condition φ_0)

Viscosity in N=4 SYM

Limitations

Summary

- At finite temperature T :

$$-dt^2 + dz^2 \rightarrow -f(z)dt^2 + dz^2/f(z) \quad \text{with } f(z) = 1 - (\pi z T)^4$$

- $f(z) = 0$ at $z = 1/\pi T \Rightarrow$ **black hole horizon**

- Ordinary particles in 4-dimensions are the end points of strings living in the bulk. Thermal effects occur when a string gets close to the BH horizon

Viscosity in N=4 SYM

Limitations

Summary

- In SYM at $g^2 N \rightarrow \infty$, one gets $\eta/s = 1/4\pi$
- Conjecture : $1/4\pi$ is the lowest possible value for η/s

Limitations

Summary

Importance of scale violations near T_c

- Is the QGP at $T/T_c \sim 2 - 3$ really strongly coupled? For quantities such as the entropy, perturbative techniques (+resummations) lead to sensible results in this region

- At $T < 3T_c$, the coupling may indeed be strong, but scale violations make AdS/CFT unreliable

Viscosity in N=4 SYM

Limitations

Summary

- QCD in heavy ion collisions displays a very rich spectrum of phenomena
- Ab initio methods (lattice) are practical only for certain quantities
- The consequence of this is the diversity of tools and techniques that have been developed to study various aspects of strong interactions in heavy ion collisions
- QCD also plays a role in providing inputs into a number of effective descriptions such as kinetic theory and hydrodynamics
