Stabilization of the electroweak vacuum by a scalar threshold effect

mercredi 6 mars 2013 19:10 (15 minutes)

Recent studies have shown that, for the current experimental values of M_H , M_t and α_s , the SM scalar potential develops a second minimum, deeper than the electroweak (EW) one. I will review a simple and efficient mechanism to stabilize the EW vacuum. The mechanism involves an extra scalar singlet and can be operative in existing see-saw, invisible axion and unitarized Higgs inflation models.
