

# Direct Dark Matter search with noble liquids

*Luca Scotto Lavina*

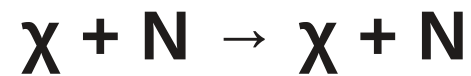

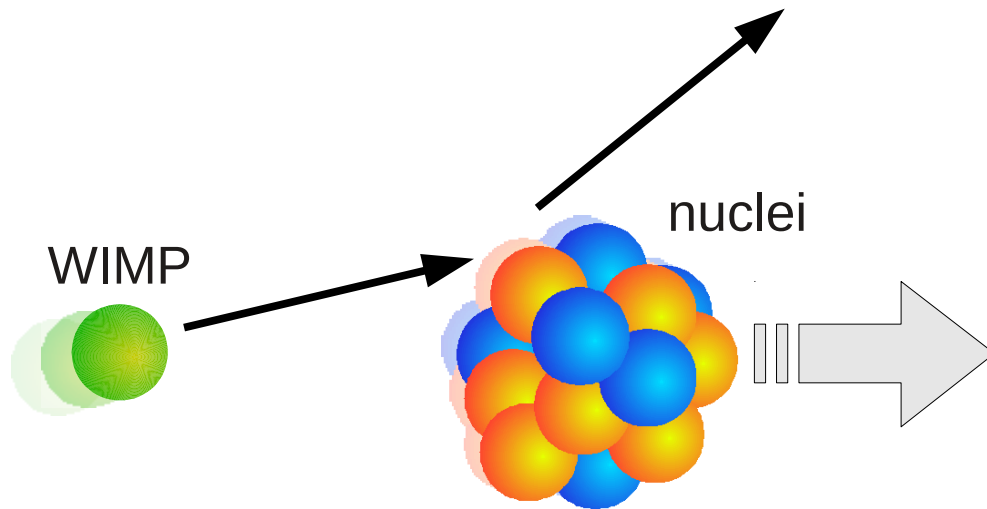

Laboratoire

Nantes, France

# WIMP-nucleon scattering

WIMP elastically scatters off nuclei  $\rightarrow$  nuclear recoils

$$\begin{aligned} v &\sim 230 \text{ km/s} \\ m_\chi &= 10 - 10^4 \text{ GeV}/c^2 \\ \rho_\chi &\sim 0.3 \text{ GeV}/c^2/\text{cm}^3 \end{aligned}$$

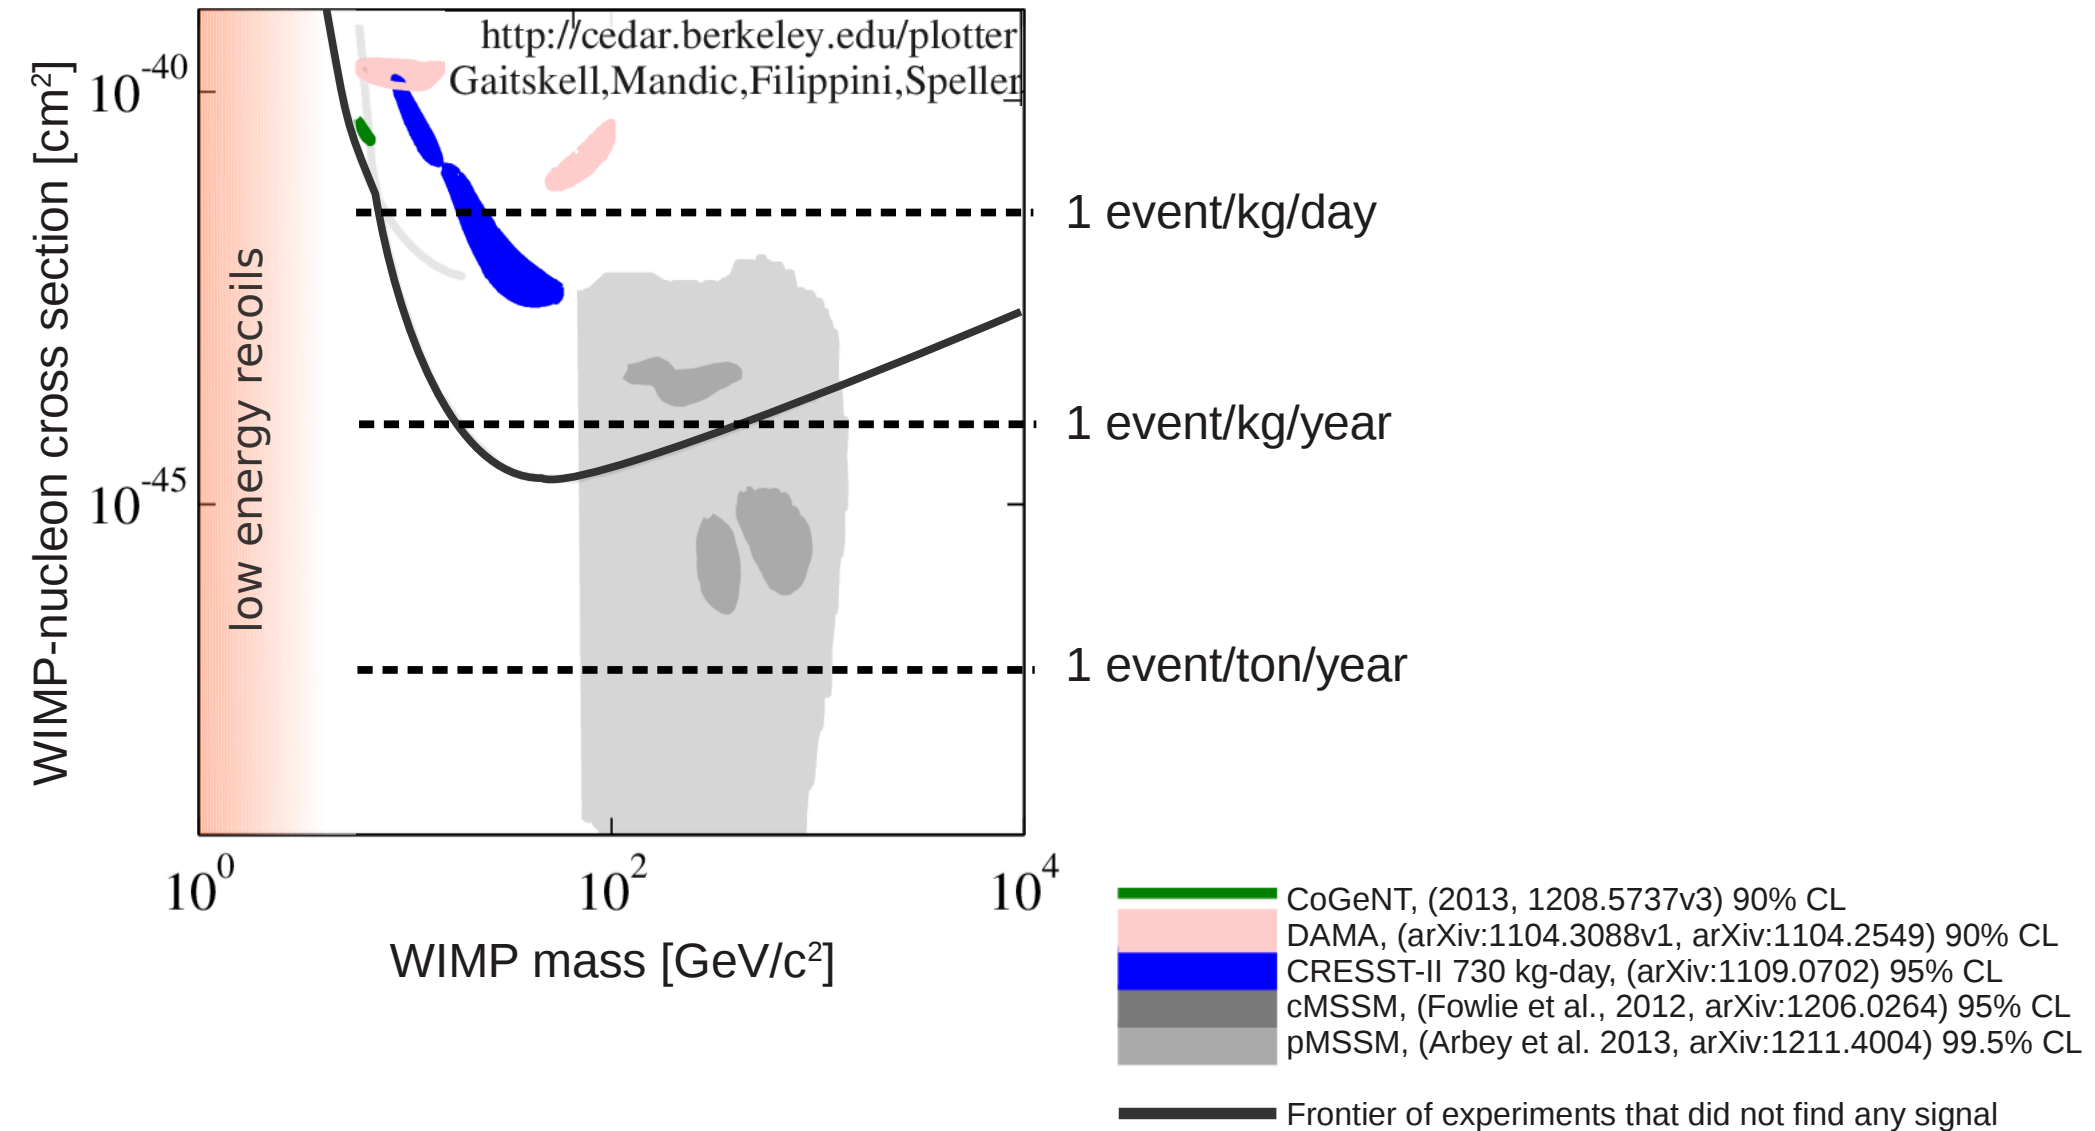

Small recoil energy

$$E = \frac{\mu^2 v^2}{m_N} (1 - \cos\theta) \lesssim 100 \text{ keV}$$

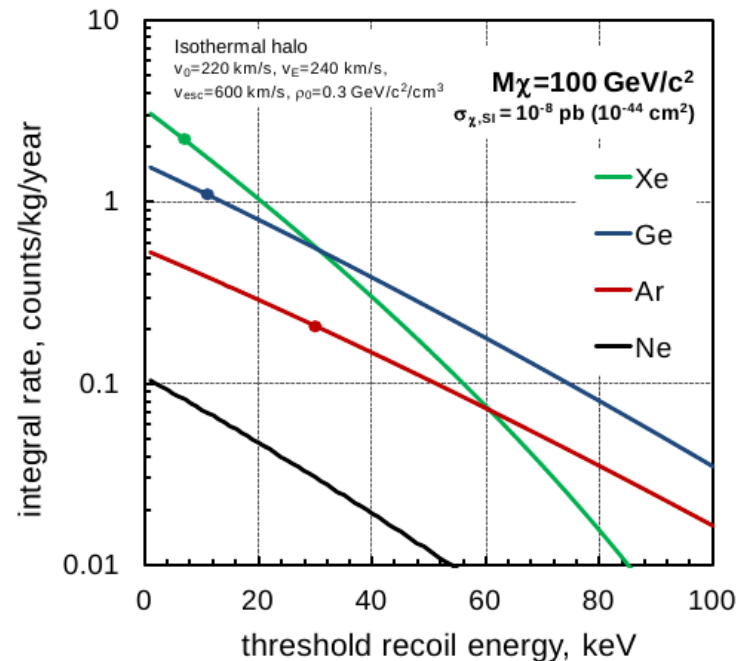

Small event rate

$$\frac{dR}{dE} = \frac{\rho_\chi}{m_\chi} \frac{\sigma |F(E)|^2}{2\mu_p^2} \int_{v_{\min}(E)}^{v_{\text{esc}}} d^3v \frac{f_\oplus(\vec{v}, t)}{v}$$

# Hunting WIMPs ...

# Noble gases used as target for direct Dark Matter search

	Neon	Argon	Xenon
Atomic number	10	18	54
Atomic mass	20.2	40.0	131.3
Boiling point [K]	27.1	87.3	165.0
Liquid density @ $T_b$ [g/cm <sup>3</sup> ]	1.21	1.40	2.94
Ionization ( $W$ [eV])		23.6	15.6
Scintillation ( $W_{ph}^{a,\beta}$ [eV])		27.1, 24.4	17.9, 21.6
Scintillation wavelength [nm]	78	128	178
Abundance [ppm]	18.2	9340	0.09

# Argon

Ar

- Large abundance (~1% of air)
  - modest prices in natural composition
  - huge detectors feasible
- Relatively compact detectors
  - exploit self shielding
- Cryogenics at  $-180^{\circ}\text{C}$
- Scalability to larger detectors
- Excellent background discrimination
  - scintillation/ionization
  - pulse shape discrimination (scintillation)

WARP, ArDM, DEAP, CLEAN, DarkSide, . . .

- Small  $\lambda = 128\text{nm}$ 
  - need to „shift“ light

- Wavelength shifters on PMTs and/or TPC surfaces (e.g. TPB → 420 nm)

- Very high background from  $^{39}\text{Ar}$  ( $^{39}\text{Ar}/^{40}\text{Ar} \sim 8 \cdot 10^{-16}$ ) ( $\beta^-$  emitter:  $Q=565\text{ keV}$ ,  $t_{1/2}=269\text{y}$ ),  $\sim 1\text{ Bq/kg}$ 
  - limitation on detector size
  - limitation on energy threshold

- Use of low-radioactivity Argon:
  - depleted Argon
  - underground gas wells
  - Concentration  $\ll 5\%$  than natural one

# Xenon

Xe

- No long lived Xe isotopes
- High mass number ( $A \sim 131$ )
  - high rates
- High atomic number ( $Z=54$ ) and density ( $\rho \sim 3\text{kg/l}$ )
  - compact detectors
  - self shielding
- 50% non-zero spin isotopes
- Cryogenics at  $-100^\circ\text{C}$ 
  - relatively easy to handle
- Scalability to larger detectors
- Good background discrimination
  - scintillation/ionization

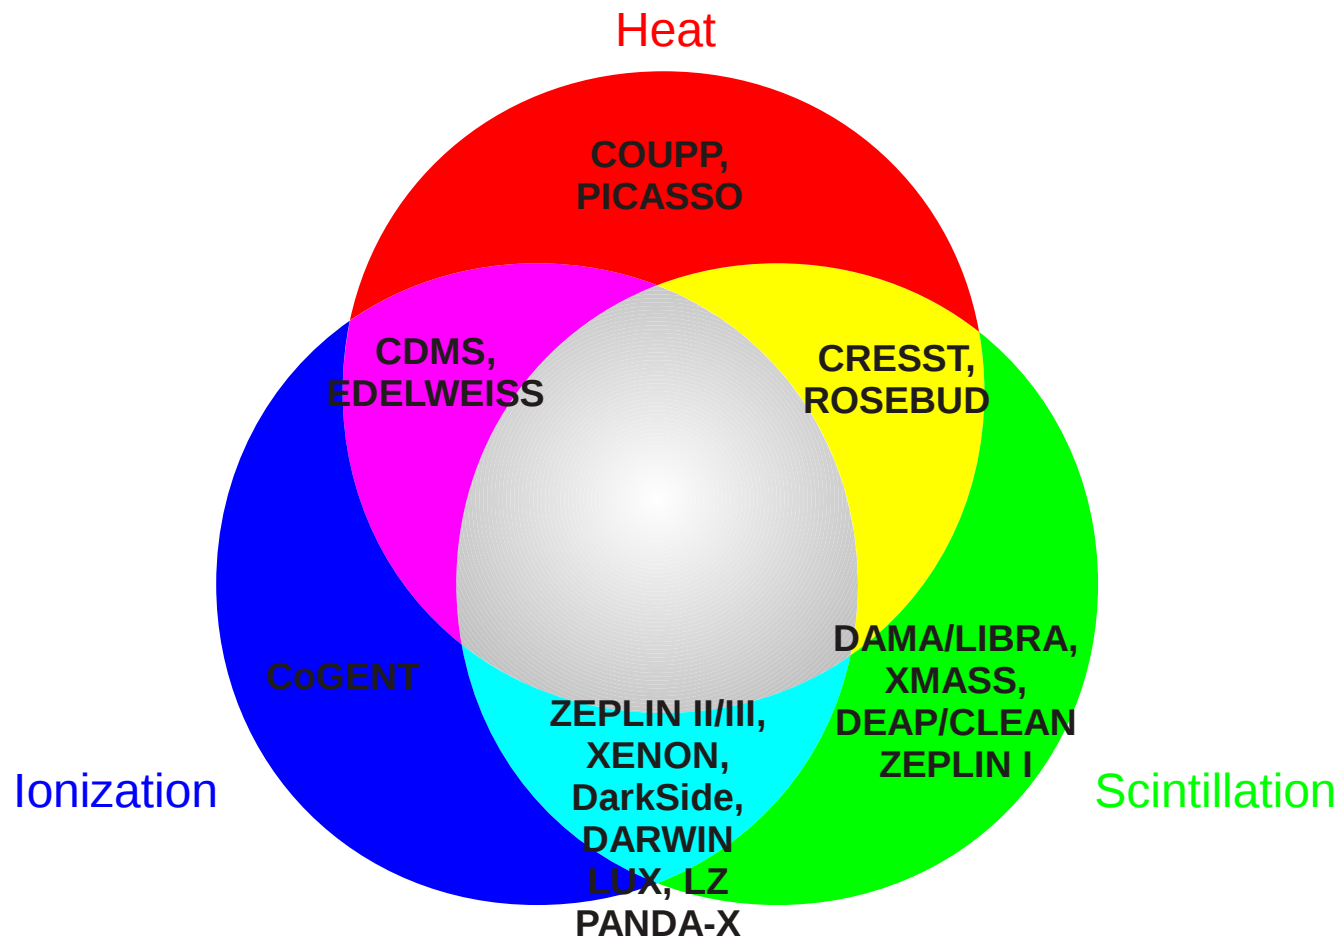

- Pulse shaping discrimination not used
  - $\tau = O(1) - O(10) \text{ ns}$

- Quite expensive

ZEPLIN, XENON, PandaX, XMASS, LUX, . . .

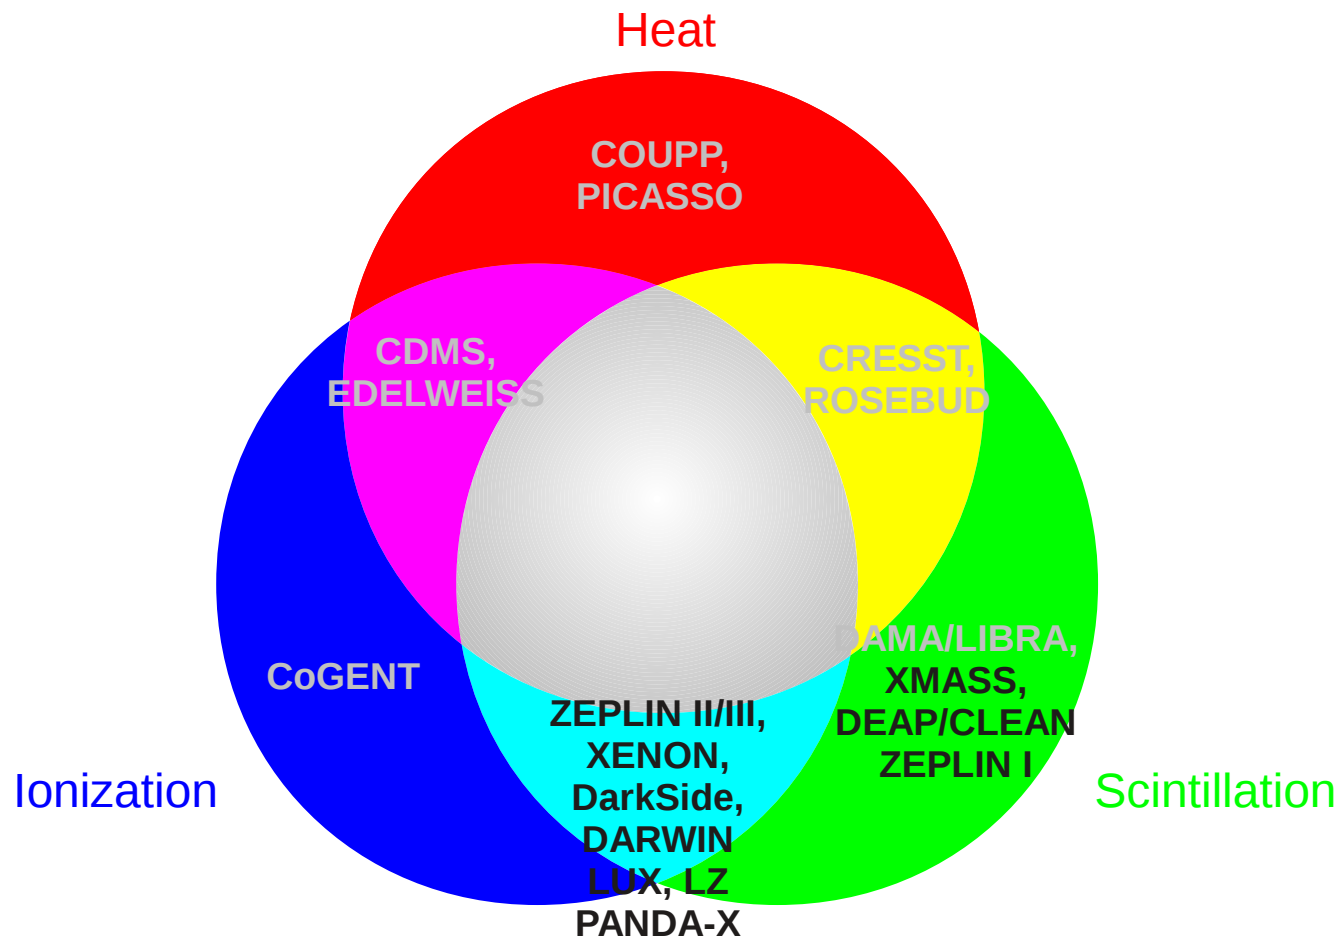

# Energy recoil detection

Energy recoil is transferred to three possible phenomena: **scintillation**, **ionization**, **heat**  
One or two among these three signals are used for particle detection.

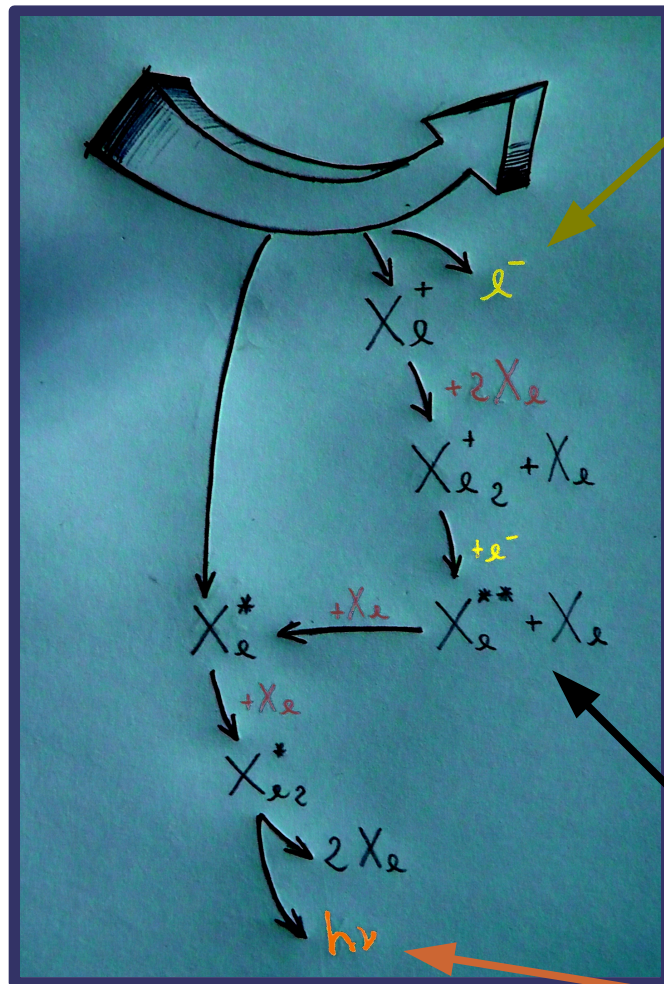

# Neon, Xenon and Argon based detectors

Energy recoil is transferred to three possible phenomena: **scintillation**, **ionization**, **heat**  
One or two among these three signals are used for particle detection.  
This talk will focus only on detectors using Ne, Xe, Ar

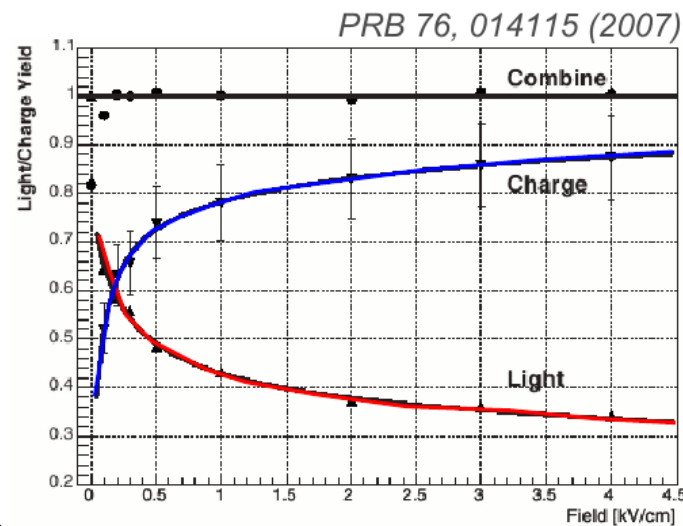

# Focusing on scintillation and ionization

Argon and xenon : similar mechanism

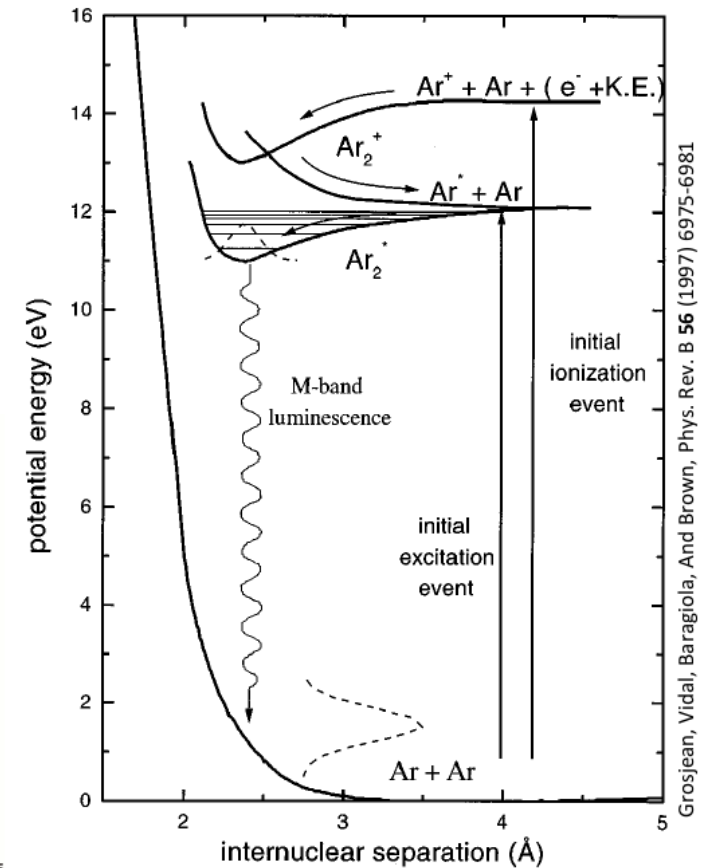

Extracted with an E field

Recombination, absent at high fields (few kV/cm)

VUV

Response depends on particle type and energy!

Grosjean, Vidal, Baragiola, And Brown, Phys. Rev. B 56 (1997) 6975-6981

# The nuclear recoil energy scale

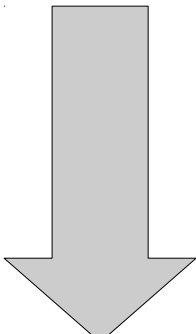

The energy deposit of a nuclear recoil is usually computed through the expression:

$$E_{nr} = \frac{S1}{L_{eff} \cdot Y_{er}} \cdot \frac{S_{er}}{S_{nr}}$$

Detected scintillation signal (points to  $S1$ )

Field quenching corrections (points to  $\frac{S_{er}}{S_{nr}}$ )

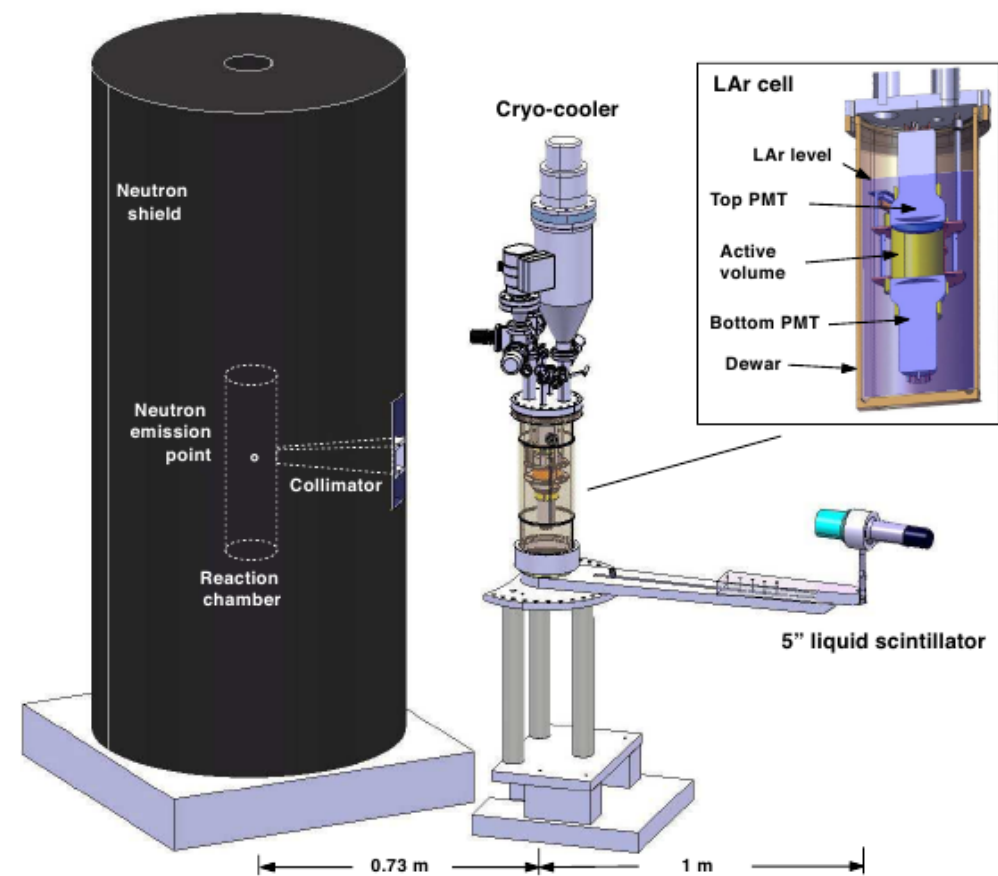

Measured light yield for a reference  $\gamma$ -ray line (detector dependent)  
Usually reference is the 122 keV gamma from  $^{57}\text{Co}$  (points to  $Y_{er}$ )

$$L_{eff}(E_{nr}) = \frac{S1/E_{nr}}{Y_{er}} \cdot \frac{S_{er}}{S_{nr}} \longrightarrow \frac{Y_{nr}(E_{nr})}{Y_{er}(E_{ee} = 122 \text{ keV})}$$

$L_{eff}$  is the ratio of the scintillation yield for a nuclear recoil of given energy  $E_{nr}$  and the scintillation yield of an electronic recoil of 122 keV at 0 field

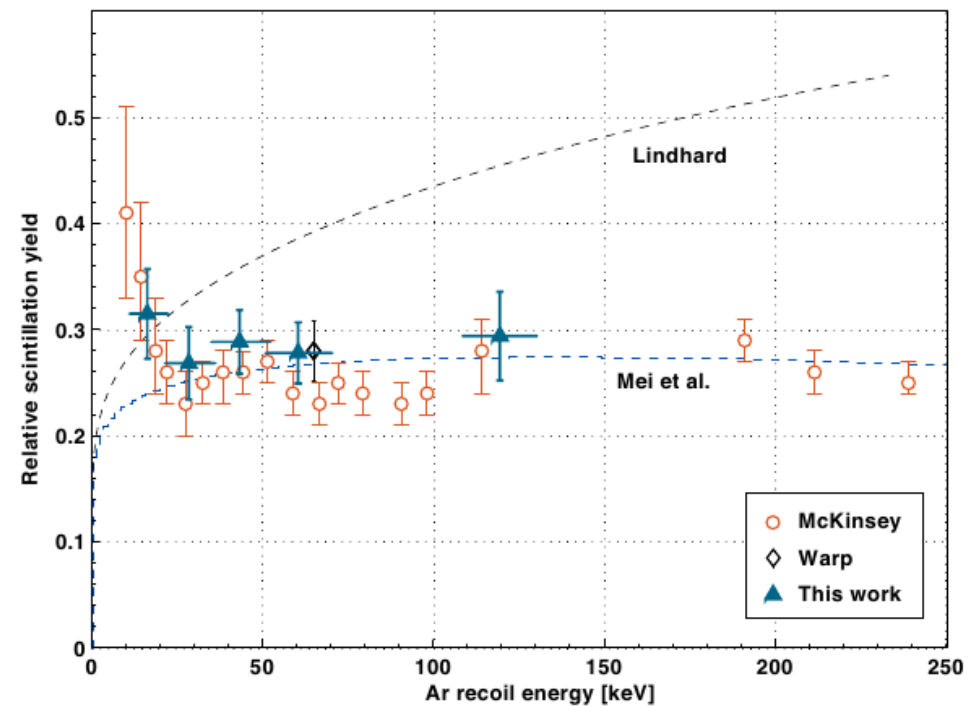

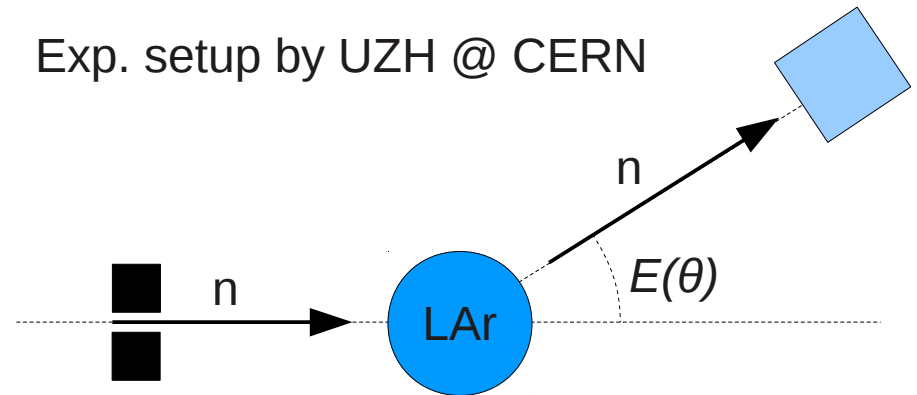

It is a property of target material, it does NOT depend on the detector !

# $L_{eff}$ in Argon

- dd fusion neutron generator ( $E_n = 2.45$  MeV)
- LAr cell as active target
- Organic liquid scintillator to detect scattered n

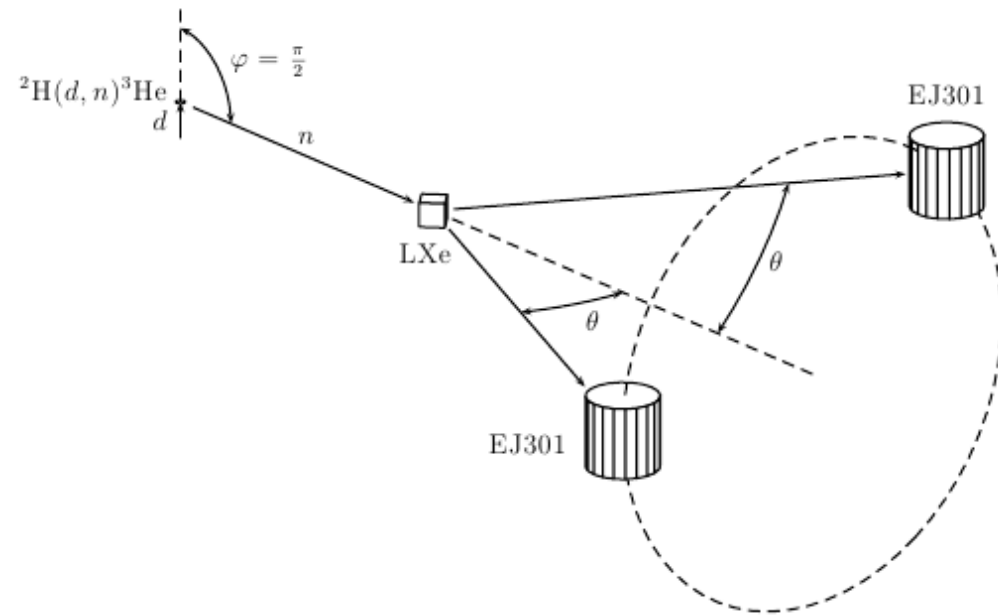

Exp. setup by UZH @ CERN

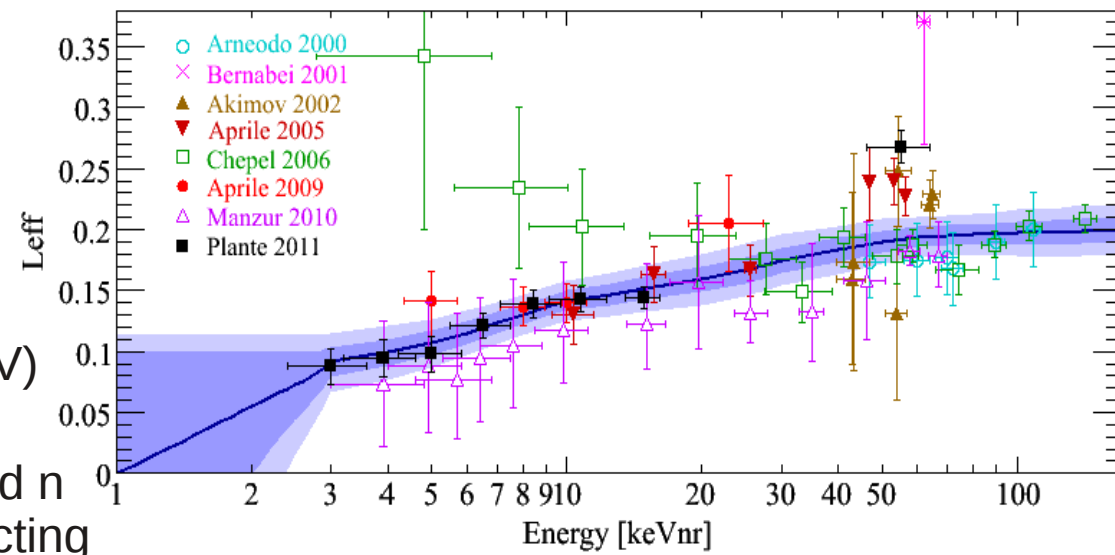

Regenfus et al, J.Phys.Conf.Ser. 375 (2012) 012019, arXiv:1203.0849

# $L_{eff}$ in Xenon

Exp. setup at Columbia University

- dd fusion neutron generator ( $E_n = 2.45$  MeV)
- LXe cell as active target
- Organic liquid scintillator to detect scattered n
- TOF cut to select only neutrons non interacting in the detector materials

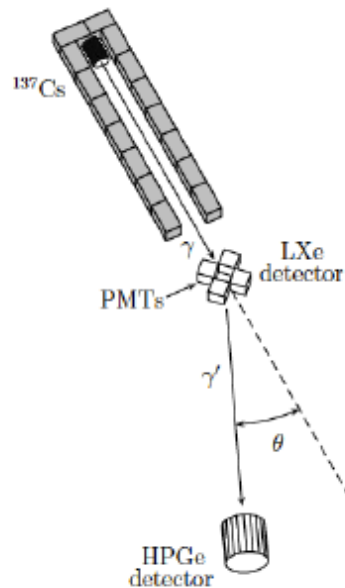

Plante et al, Phys.Rev. C84 (2011) 045805, arXiv:1104.2587

# The electron recoil energy scale in xenon

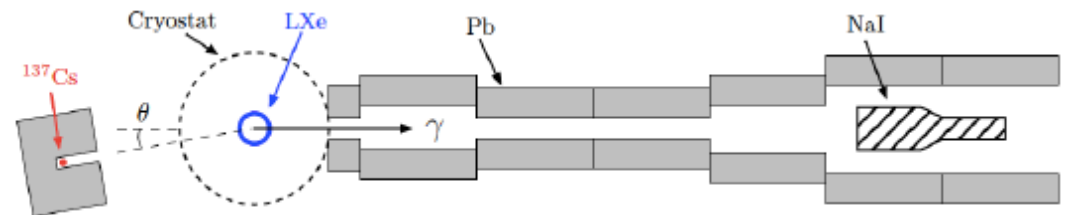

- Knowledge of the response of LXe to low energy ER is extremely important
- $^{83\text{m}}\text{Kr}$  provides 32.1 and 9.4 keV lines; but this is still “high” energy (DAMA annual modulation signal is in the 2-6 keV energy window)

Recent measurements using the “Compton coincidence” technique

$$E_{\text{er}} = E_{\gamma} - E'_{\gamma}$$
$$= E_{\gamma} - \frac{E_{\gamma}}{1 + \frac{E_{\gamma}}{m_e c^2} (1 - \cos \theta)}$$

**Columbia :** Aprile et al.,  
*Phys. Rev. D* 86, 112004 (2012)

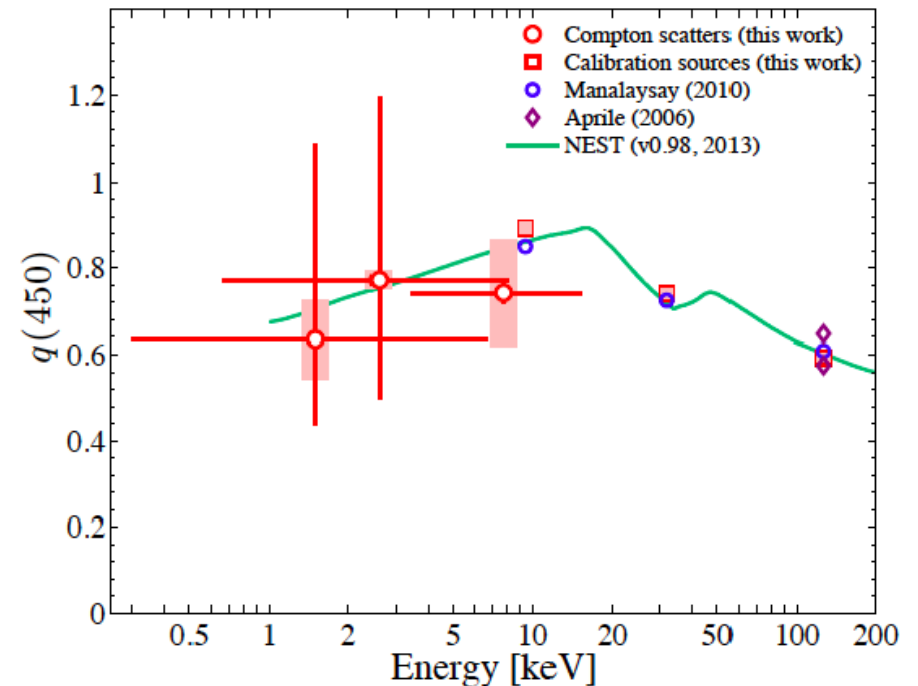

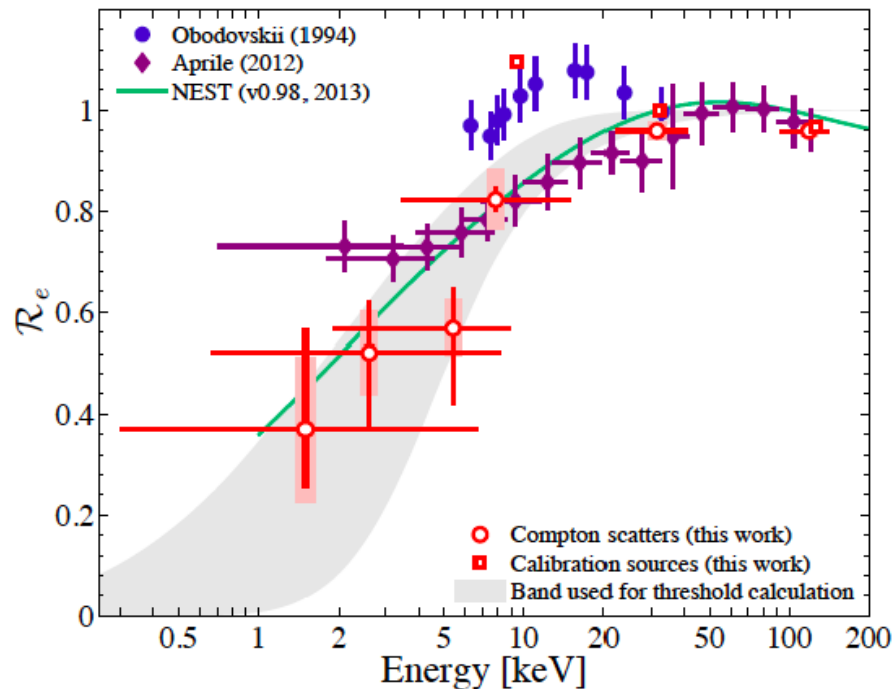

**Zurich :** Baudis et al.,  
*Phys. Rev. D* 87, 11501 (2013)  
Including field quenching

# The electron recoil energy scale in xenon

## Results of the measurements

*Baudis et al., Phys. Rev. D 87, 11501 (2013)*

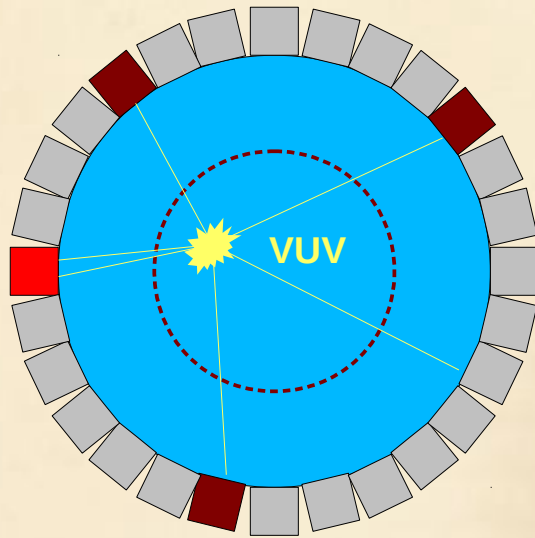

Light yield decreases at 0-field below 50 keV

- Field quenching  $\sim 75\%$  at low energies
- Derived XENON100 energy threshold: 2.3 keV  
→ sensitive to DAMA signal! Results coming soon

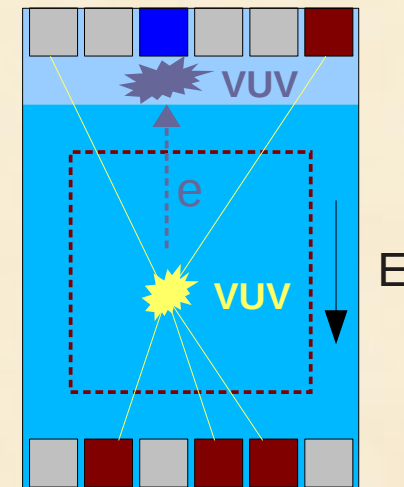

# Detecting WIMPs : single-phase vs. double-phase

## Single-phase detector

DEAP-3600 (3.6ton LAr)  
MiniCLEAN (360kg LAr / 310kg LNe)  
XMASS (835kg LXe)  
ZEPLIN I (3.1kg LXe)

## Dual-phase detector (TPC)

ArDM (1ton LAr)  
DarkSide-50 (50kg LAr)  
LUX (350kg LXe)  
PANDA-X (1ton LXe)  
XENON (14kg, 62kg, 2ton, ... LXe)  
ZEPLIN II/III (31kg, 6kg LXe)

# Background sources

## Neutrons :

(Th,U chains assumed in secular equilibrium)

- ( $\alpha,n$ ) reactions through Th, U chains

Source  $\rightarrow$  site (surrounding rock), detector components

Estimations  $\rightarrow$  More complex: material-dependent cross-section of ( $\alpha,n$ ) reactions and branching ratios for transitions to excited states. To be calculated for each relevant material in the detector

- Spontaneous U fission (mostly  $^{238}\text{U}$ )
- Induced by cosmic rays muons

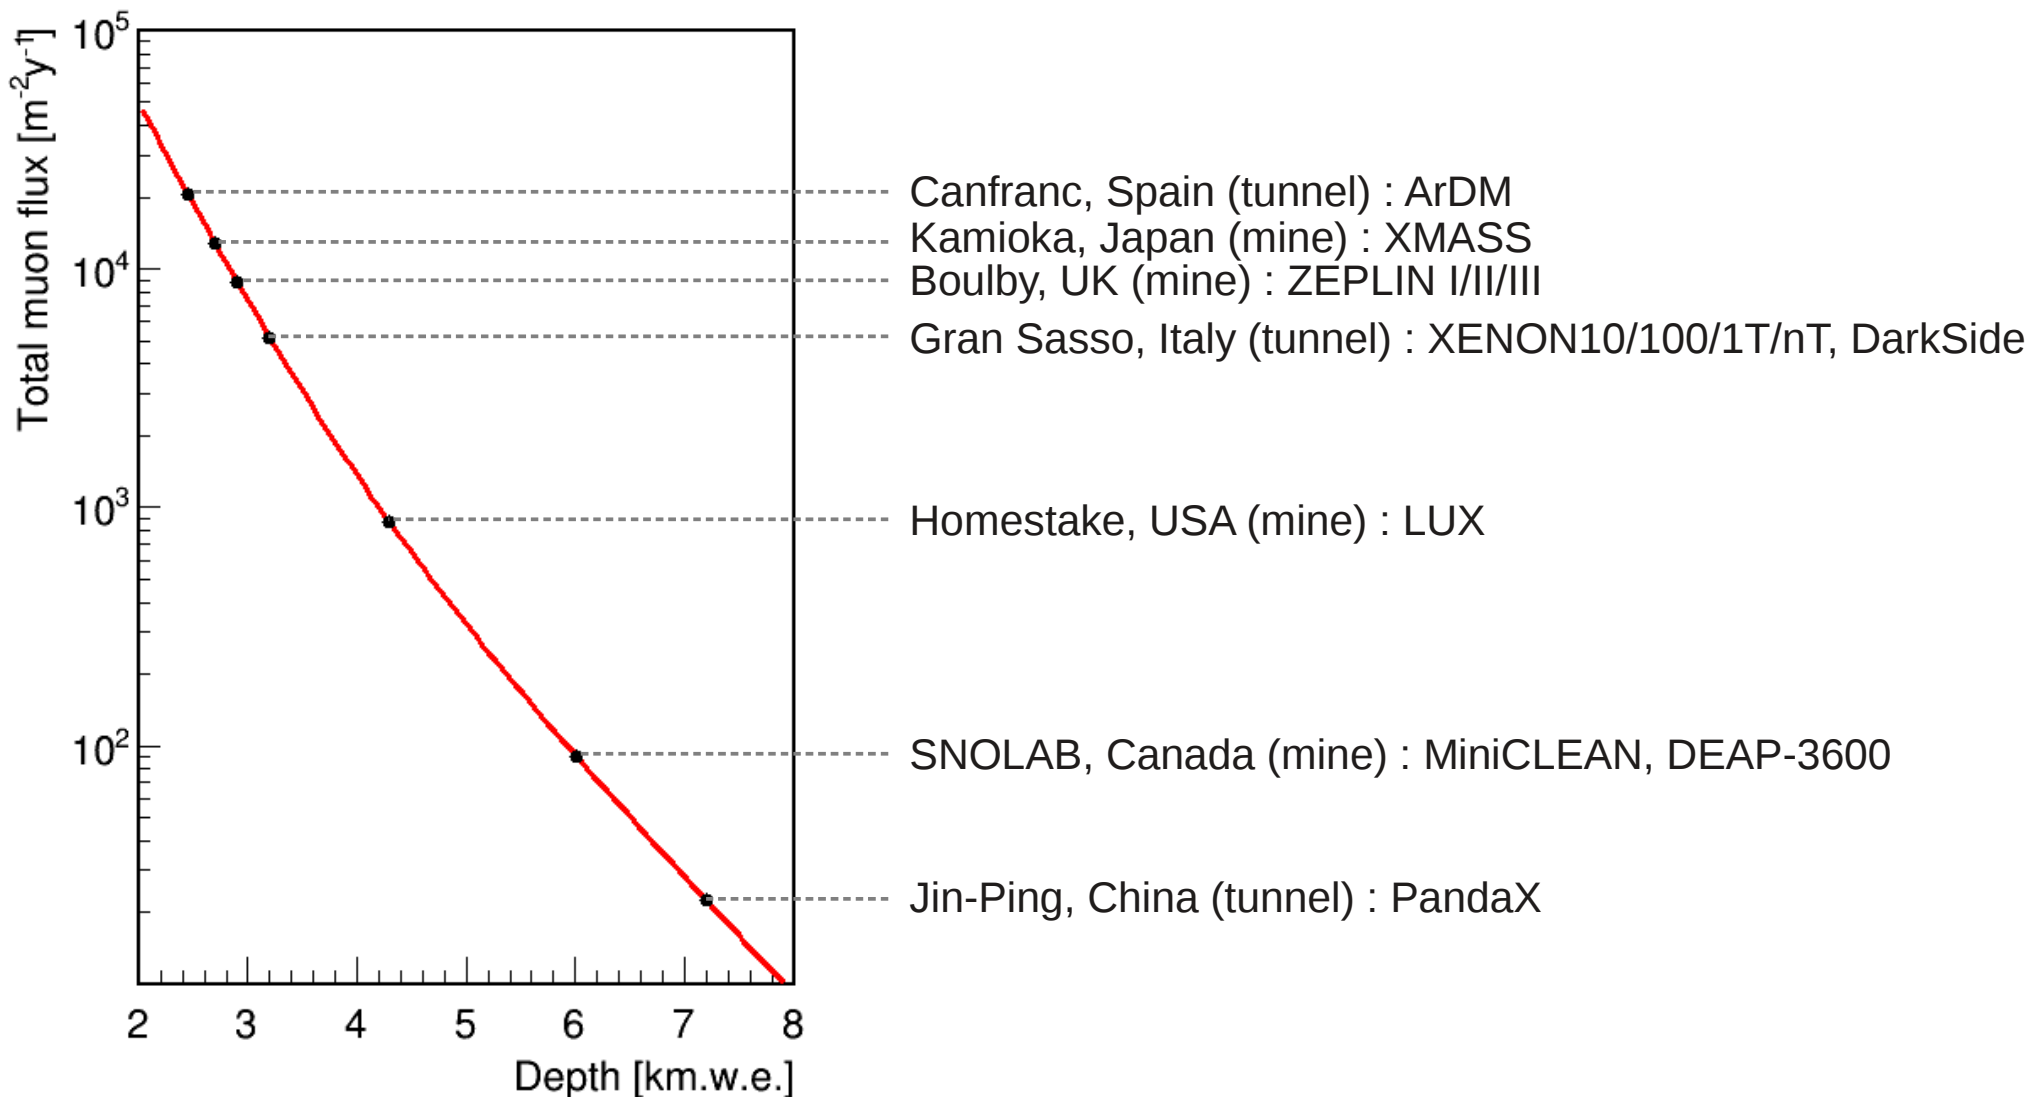

## Gamma and beta :

- $^{238}\text{U}$ ,  $^{235}\text{U}$ ,  $^{232}\text{Th}$  chains and  $^{40}\text{K}$ ,  $^{60}\text{Co}$
- “intrinsic bg” (i.e. diluted in the target):  $^{85}\text{Kr}$ ,  $^{39}\text{Ar}$ , Rn

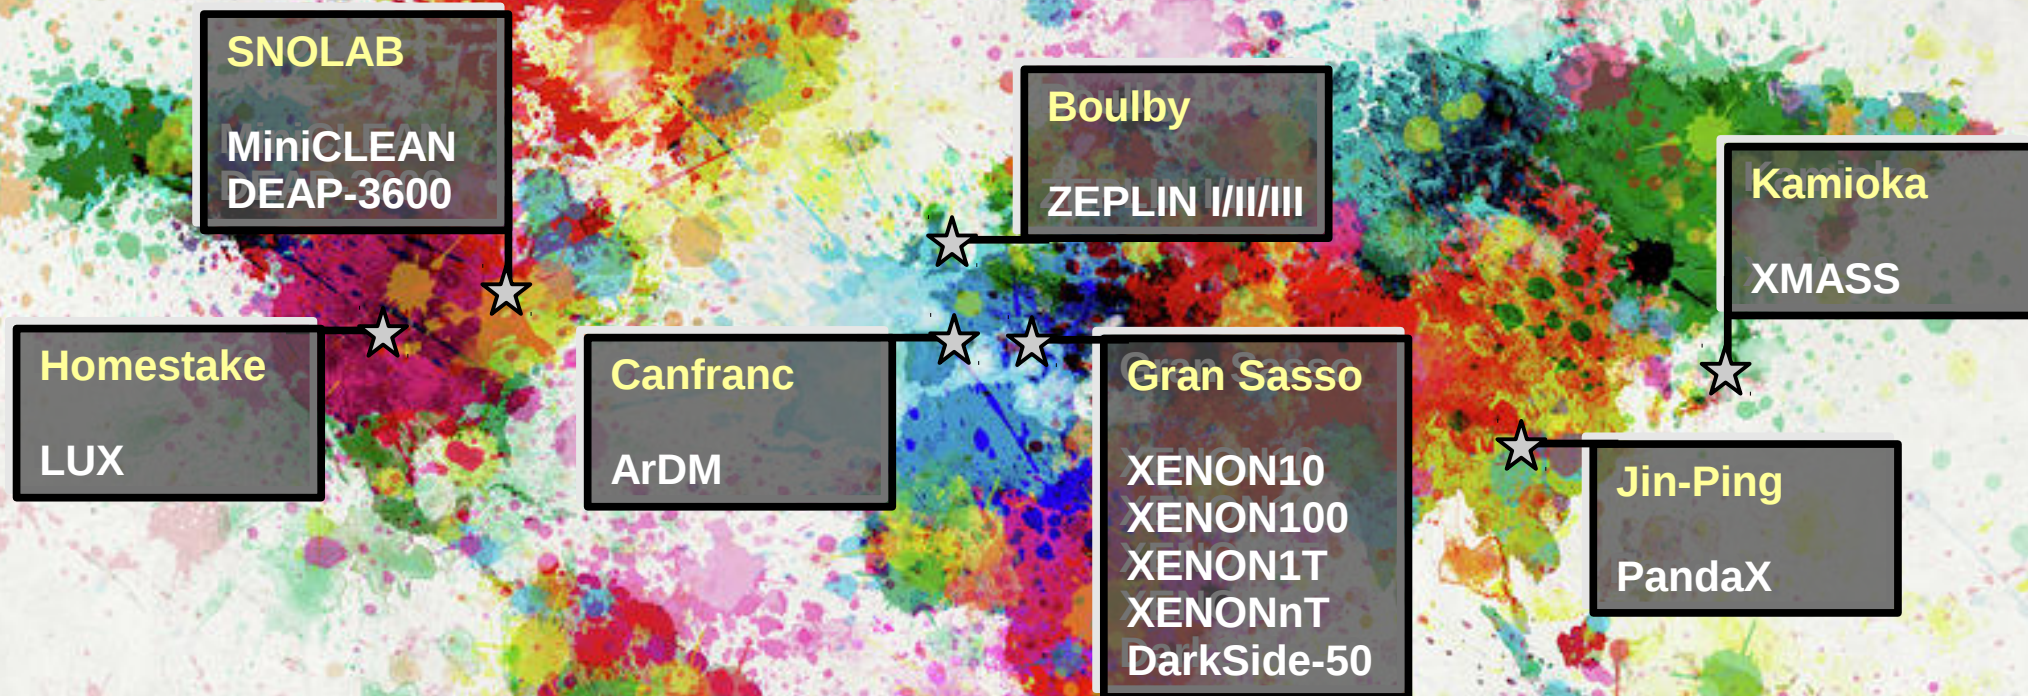

## Physical backgrounds :

- Solar neutrinos
- $^{136}\text{Xe}$   $2\nu\beta\beta$  decay

## Background suppression : natural shielding

# Noble liquid detectors for direct dark matter search

# Background suppression : detector design

Goal: avoiding background particles entering in the fiducial volume of the detector

## Use of radiopure materials :

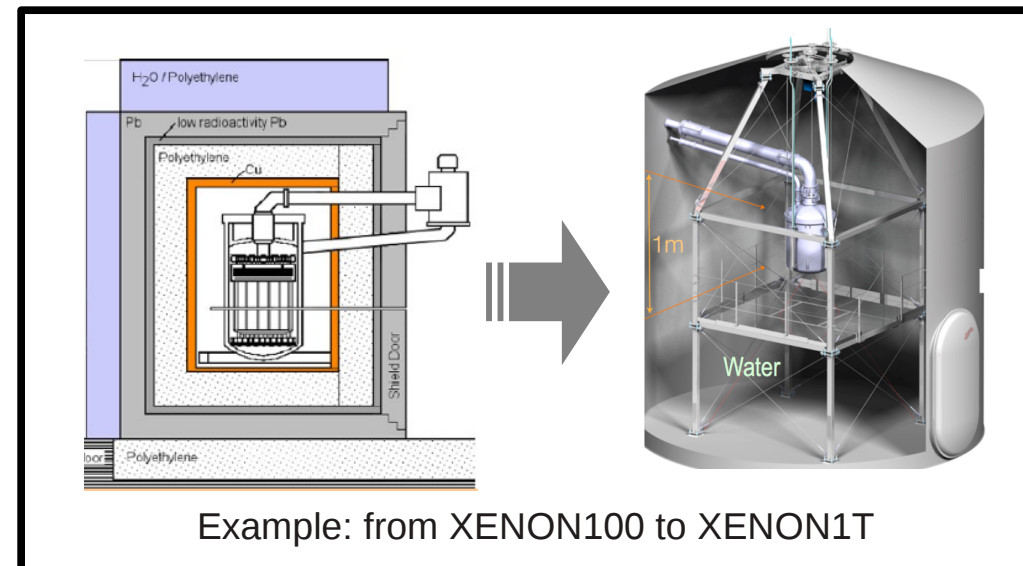

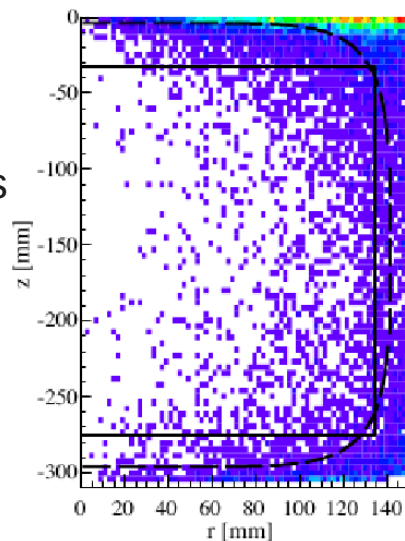

- Screening of all detector components close to the active region

## Shielding :

- Large shield (Pb, water, plastics)
- Water / liquid scintillator tanks very important for large scale detectors ( $\sim 1$  ton)
  - Water: passive or used as an active veto for muons with PMTs (Cherenkov light)

## Self-shielding :

- Active veto
- Fiducial volume cuts

Example: from XENON100 to XENON1T

# Background suppression : signal analysis

Goal: using knowledge about the expected WIMP signal

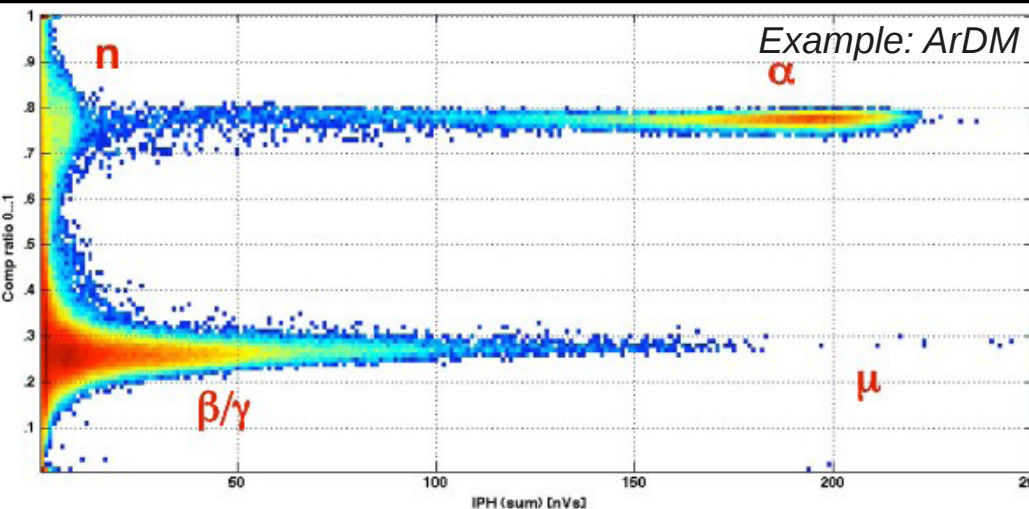

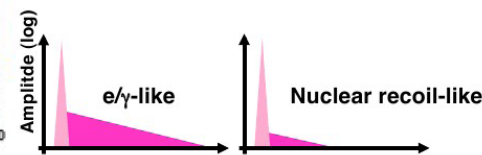

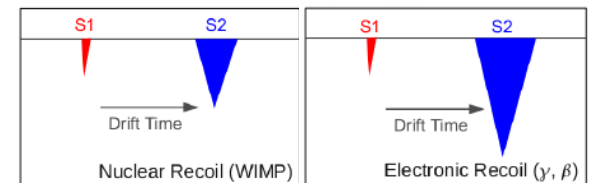

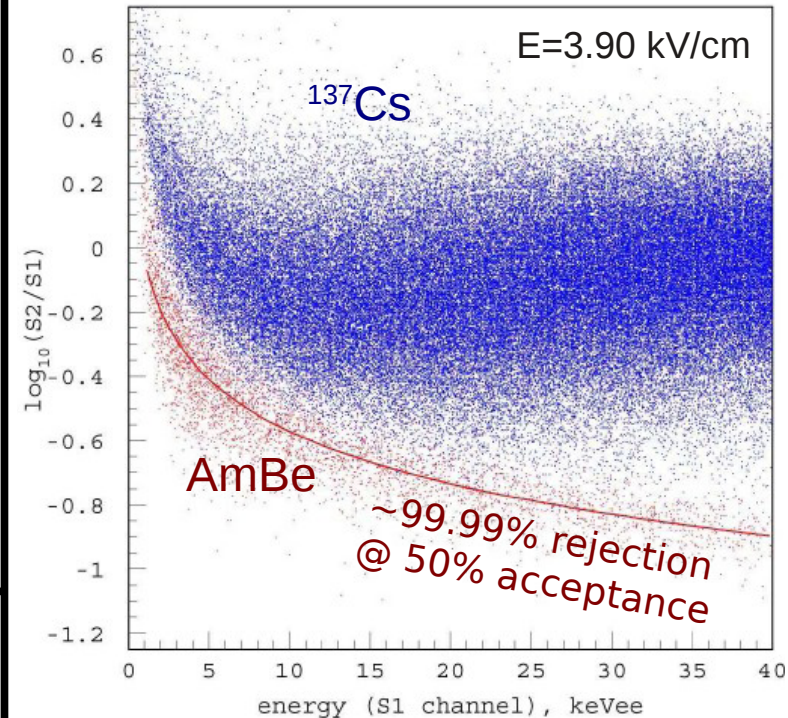

## Very low WIMP-nucleus cross section :

- Single scatter process → 3D reconstruction ability

## WIMPs interact with target nuclei :

- Nuclear recoil vs. electron recoil
  - Ionization/scintillation ratio
  - Pulse Shape Discrimination on scintillation process (strong discriminations ( $\sim 10^{-8}$ ) with Argon)

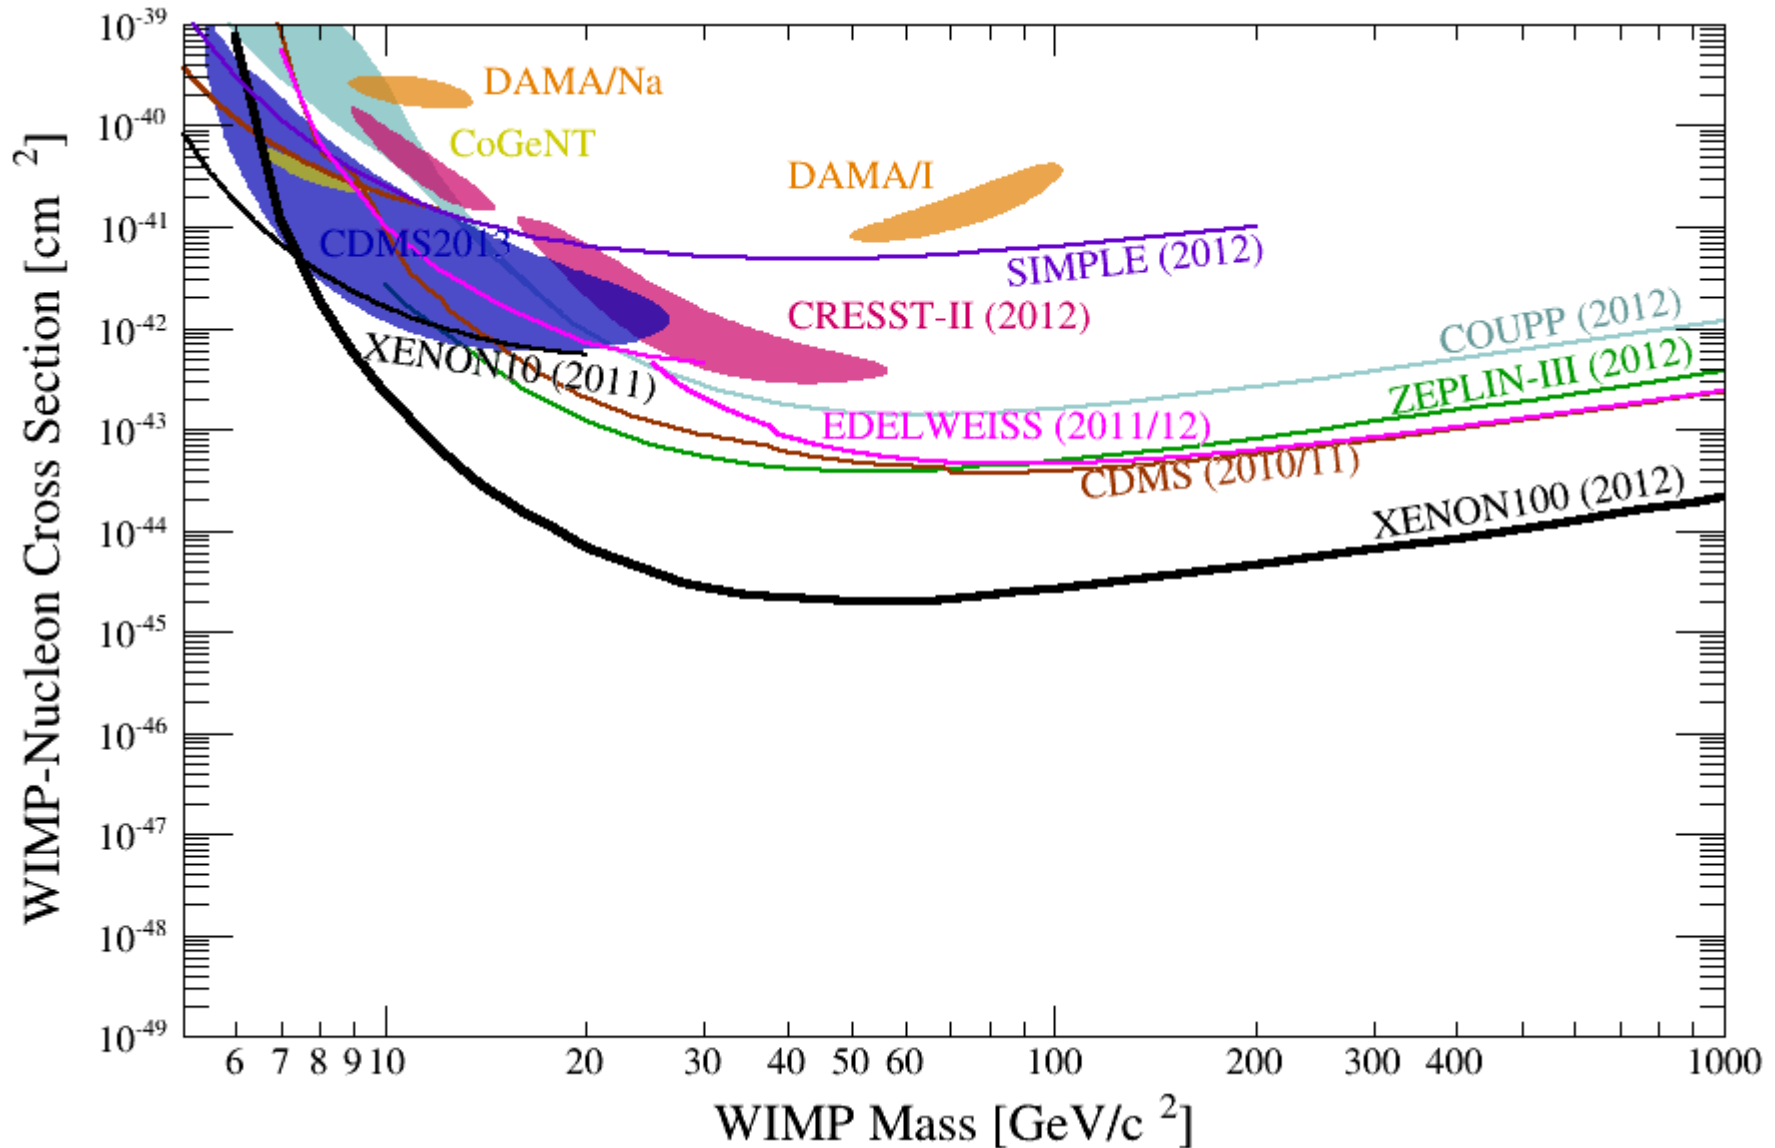

Example: ZEPLIN-III, PRD 80, 052010 (2009)

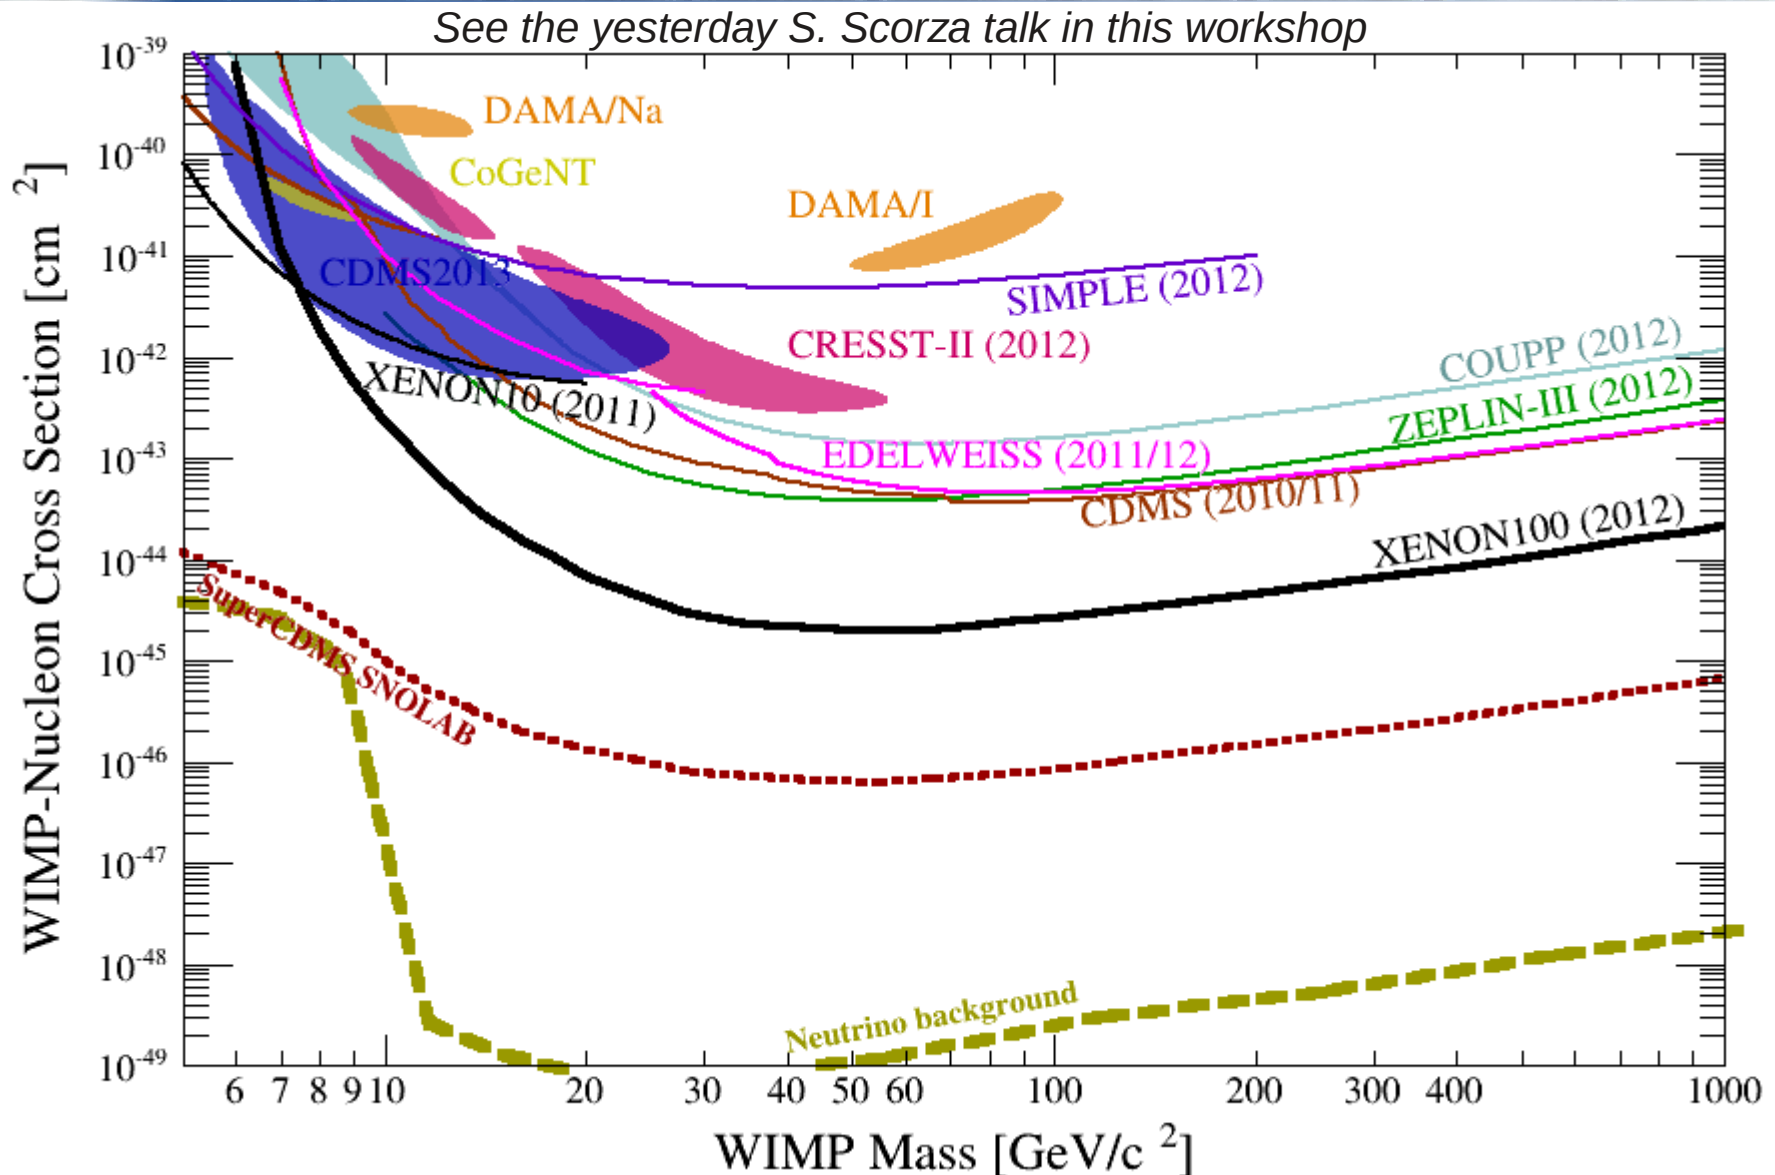

Update on current detectors

# WIMP hunting : the current WIMP hints and exclusion limits

# WIMP hunting : adding neutrino bg limit and some reference

# XENON100

## Detector :

Dual phase TPC

Target : 62 kg LXe in TPC (161 kg total)

## PMTs :

242 PMTs (low radioactivity  $<10$  mBq/PMT)

Hamamatsu R8520-06-Al 1"x1"

QE  $> 30\%$  @178 nm

## Electric fields :

Drift = 0.533 kV/cm

Extraction = 12 kV/cm (100% extraction)

## Shielding :

Passive and active (LXe veto)

*E. Aprile et al. (XENON100), Astropart. Phys. 35, 573 (2012)*

## Recent physics runs :

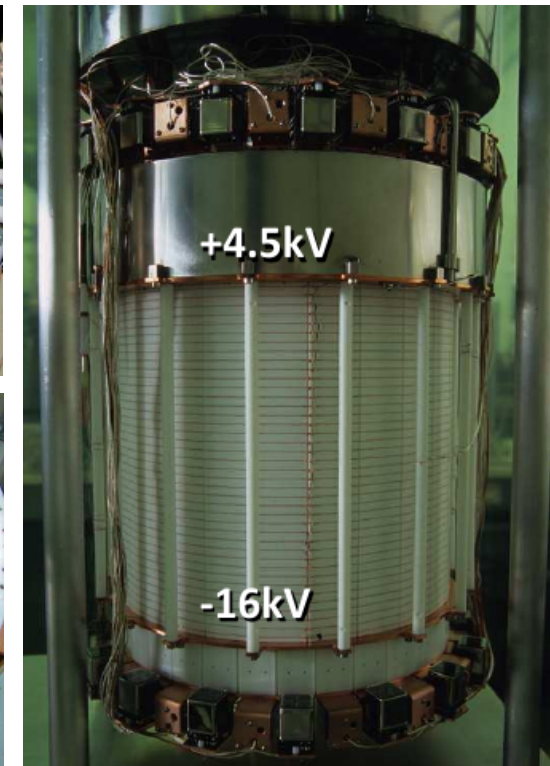

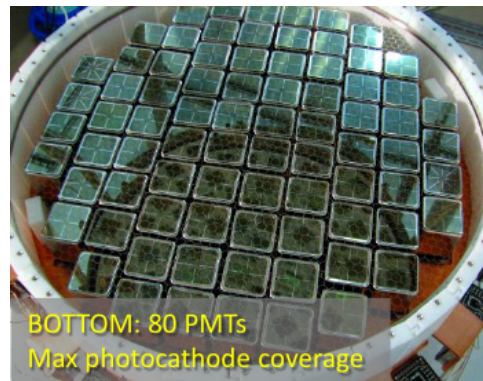

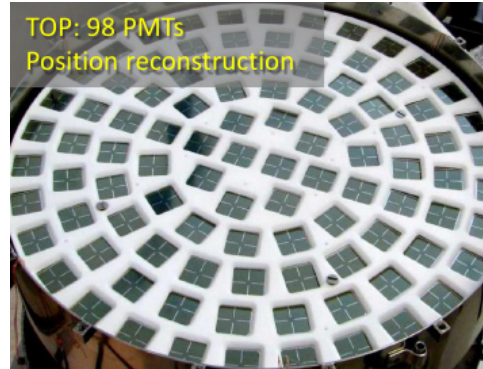

Run 8 : 100 live days (took in 2010)

*E. Aprile et al. (XENON100), Phys. Rev. Lett. 107, 131302 (2011)*

Run 10 : 225 live days (took in 2011-2012)

*E. Aprile et al. (XENON100), Phys. Rev. Lett. 109, 181301 (2012)*

Still running! (run 12, collected already  $>90$  live days)

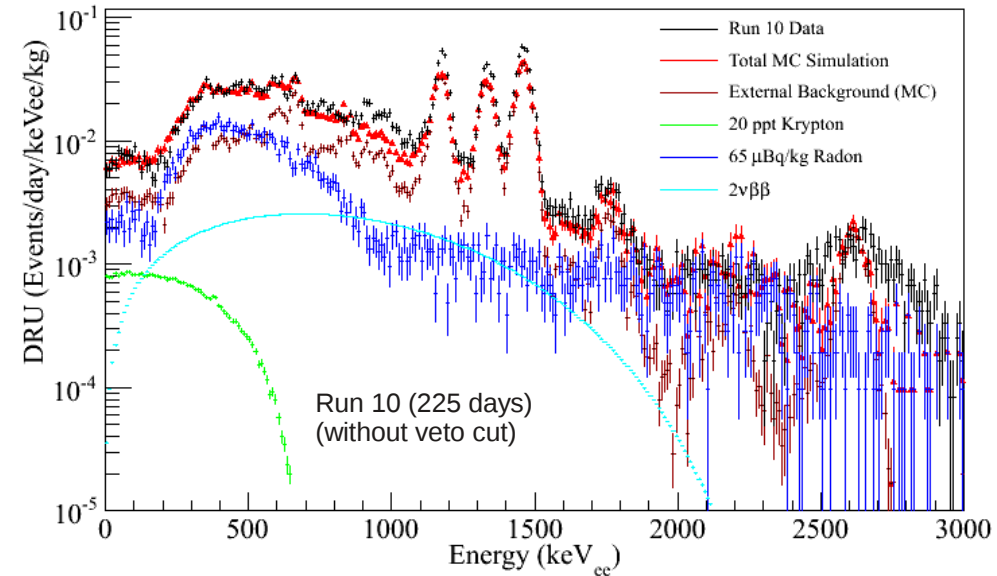

# XENON100 : background

## Electromagnetic background

*E. Aprile et al. (XENON100), Phys. Rev. D 83, 082001 (2011)*  
*E. Aprile et al. (XENON100), Phys. Rev. Lett. 109, 181301 (2012)*

- Krypton: reduced by cryogenic distillation at  $19 \pm 4$  ppt
- Excellent data/MC agreement in the full energy range
- Activity taken from screening measurements only  
(No MC rate tuning!)
- Lowest BG ever achieved in DM experiments
- BG expectation for run 10 :  $0.79 \pm 0.16$  events
- Main source of background

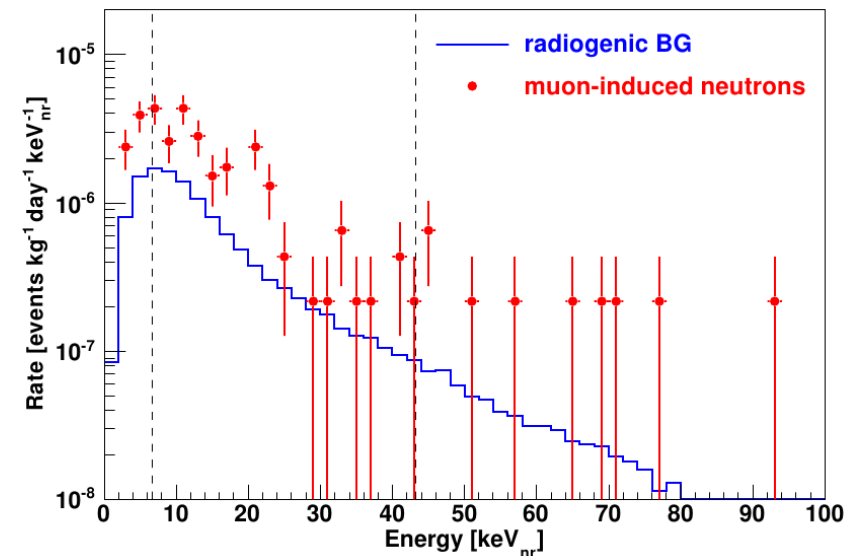

**Total background for run 10 :  $1.0 \pm 0.2$  events**

## Nuclear recoil background

*E. Aprile et al. (XENON100), J. Phys. G: Nucl. Part. Phys. 40 (2013) 115201*

- BG prediction based on MC simulations with exact geometry and measured radioactive contaminations of all the detector components
- Expectation for run 10 :  $0.17^{+0.12}_{-0.07}$  events
- Not limiting the sensitivity of the experiment

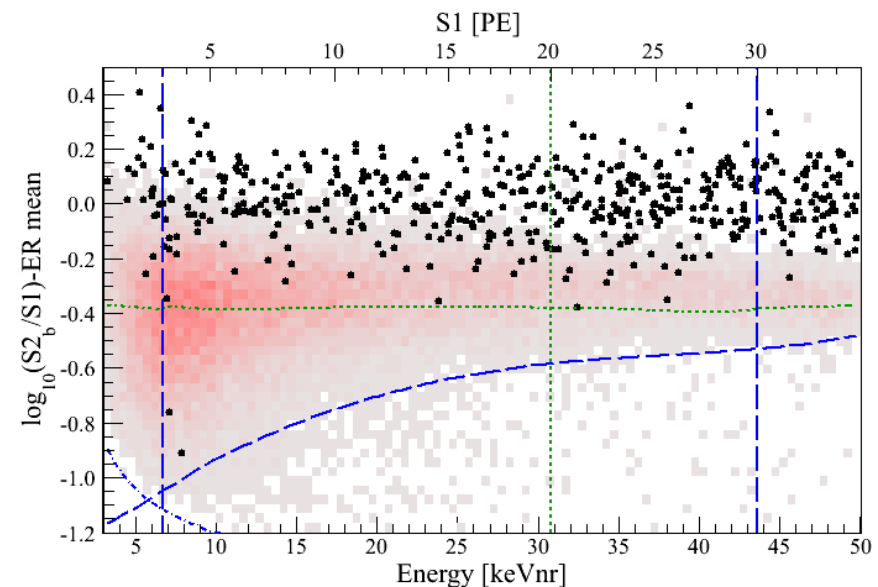

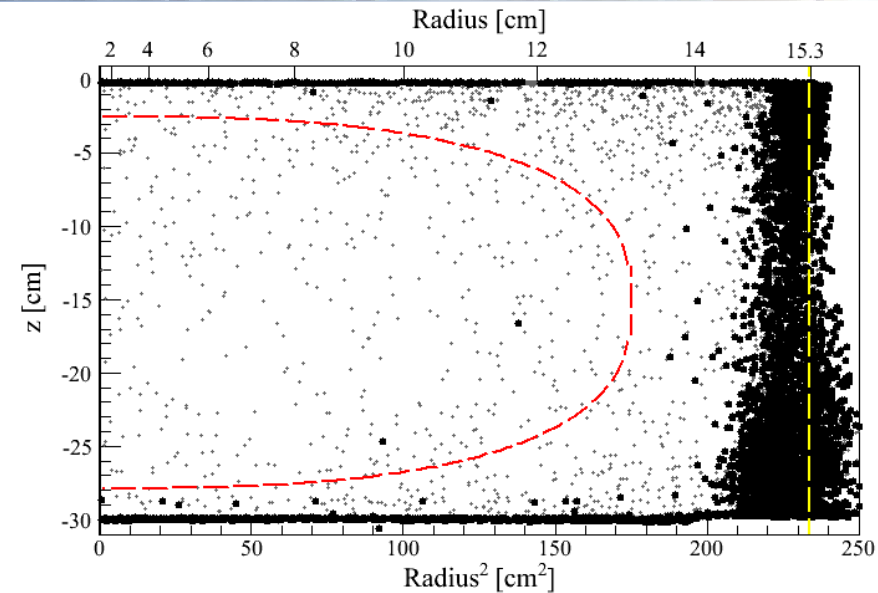

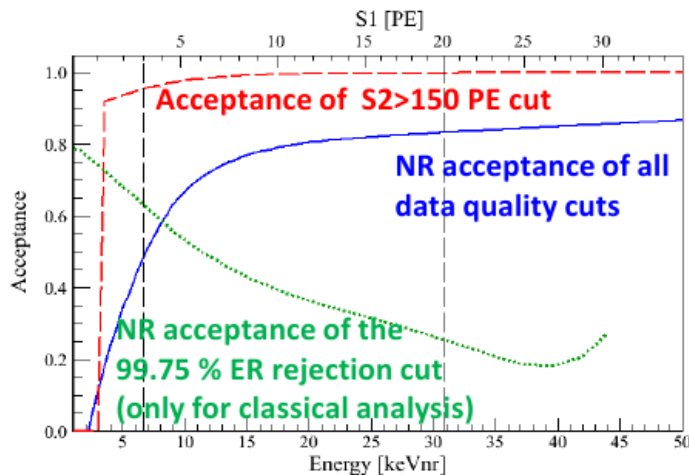

# XENON100 : latest results

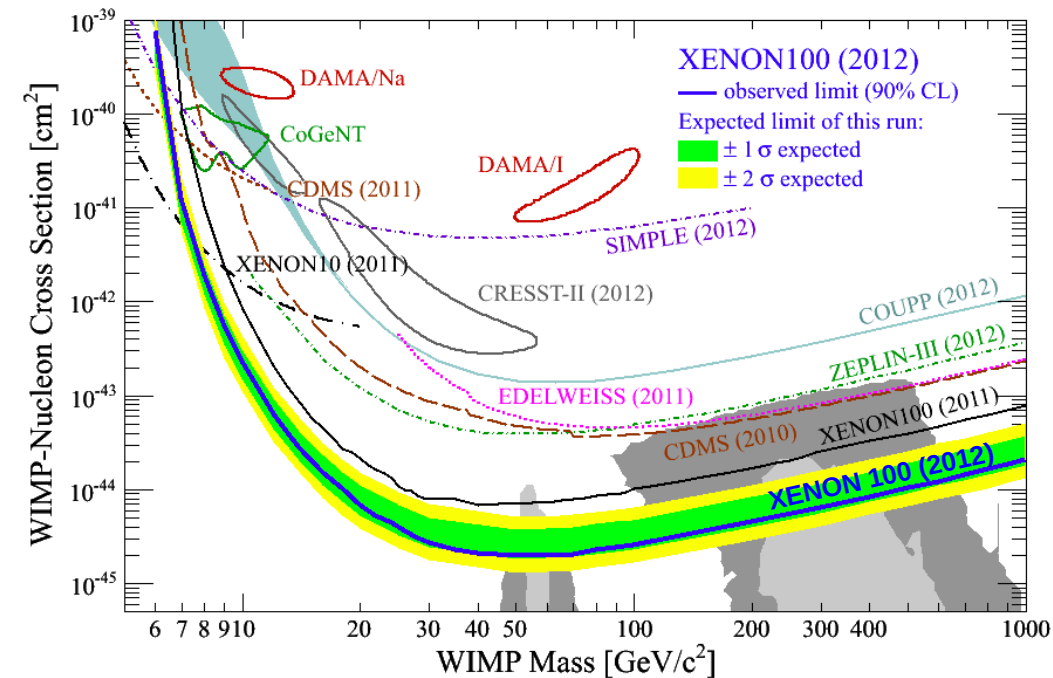

## Analysis of latest published data

*E. Aprile et al. (XENON100), Phys. Rev. Lett. 109, 181301 (2012)*

- run 10
  - 224.6 live days
  - 34 kg fiducial volume
  - Data blinded in WIMP region of interest
  - Analysis fixed before data unblinding
  - 2 candidates found (7.1 and 7.8 keV<sub>nr</sub>) in the predefined benchmark region where  $1.0 \pm 0.2$  events were expected
  - 26.4% Poisson probability that background oscillated to 2 events
  - PL analysis does not reject the background only hypothesis
    - No evidence of dark matter in the data
    - Calculate upper limit with Profile Likelihood method
- (E. Aprile et al. (XENON100), Phys. Rev. D 84, 052003 (2011))*

# XENON100 : Spin-Independent cross section

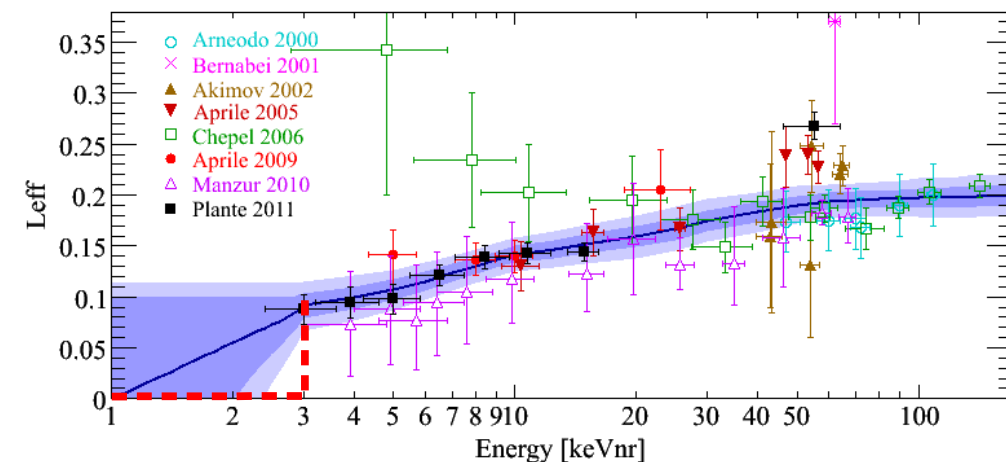

## Spin-independent cross section

*E. Aprile et al. (XENON100), Phys. Rev. Lett. 109, 181301 (2012)*

- World's most sensitive limit over a large WIMP mass range :  $\sigma_{\text{SI}} < 2.0 \times 10^{-45} \text{ cm}^2$  @  $55 \text{ GeV}/c^2$  90% CL
- It excludes part of the predicted region for SUSY candidates and other signal indications above (CoGeNT, DAMA, CRESST-II)

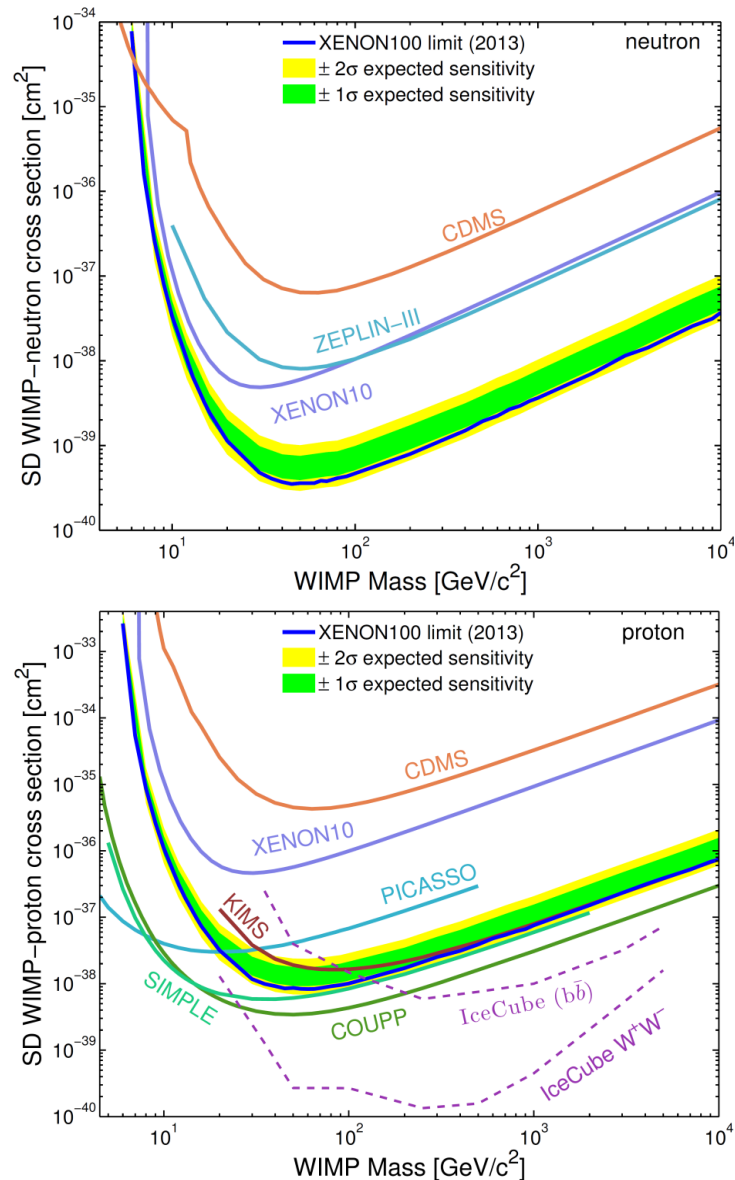

Theory region combined from:  
*Streve et al., JCAP 1203, 030(2012)*  
*Fowlie et al., arXiv:1206.0264*  
*Buchmueller et al., arXiv:1112.3564*

$v_0 = 220 \text{ km/s}$     $v_{\text{esc}} = 544 \text{ km/s}$     $\rho_0 = 0.3 \text{ GeV}/\text{cm}^3$

- $L_{\text{eff}}$  global fit of available data
- Blue band represents uncertainties
- Logarithmic extrapolation below  $3 \text{ keV}_{\text{nr}}$  to  $L_{\text{eff}} = 0$  at  $1 \text{ keV}_{\text{nr}}$  (including large uncertainty)
- Result fluctuates by just 5% if we use the strong assumption that  $L_{\text{eff}} = 0$  at  $E < 3 \text{ keV}_{\text{nr}}$  (dashed red line)

# XENON100 : Spin-Dependent cross section

## Spin-independent cross section

*E. Aprile et al. (XENON100), Phys. Rev. Lett. 111, 021301 (2013)*

- Isotopes with a non-zero nuclear spin:  
→ 26.2% of  $^{129}\text{Xe}$  ( $J^\pi = 1/2^+$ ) and 21.8% of  $^{131}\text{Xe}$  ( $J^\pi = 3/2^+$ )
- Set limit on pure WIMP-neutron and pure WIMP-proton cross sections
- Same data and event selection as the SI search
- Nuclear model used: *Menendez et al., Phys. Rev. D86, 103511 (2012)*
- Most sensitive limit on pure neutron coupling above  $6 \text{ GeV}/c^2$   
→  $\sigma_n < 3.5 \times 10^{-40} \text{ cm}^2$  @  $45 \text{ GeV}/c^2$  90% CL
- Competitive limit on pure proton coupling  
→ weaker sensitivity because  $^{129}\text{Xe}$  and  $^{131}\text{Xe}$  have an unpaired neutron but even number of protons

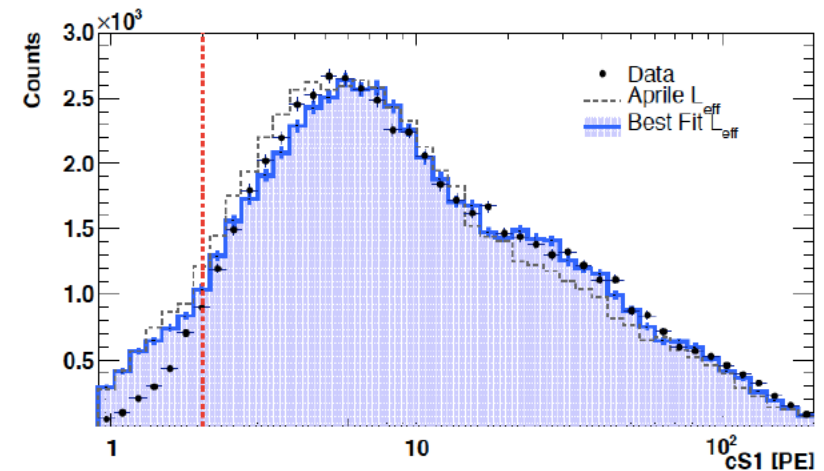

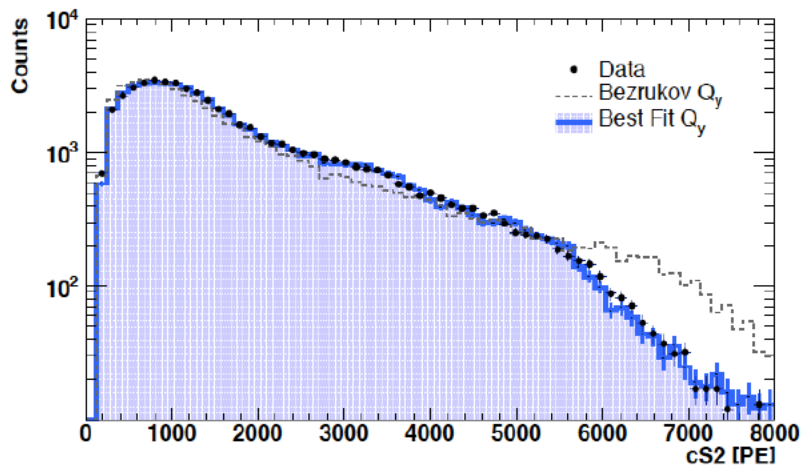

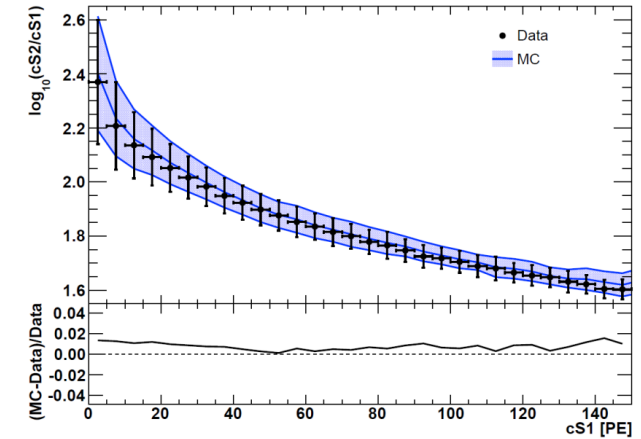

# XENON100 : Control on systematics with AmBe data

## Response of the XENON100 dark matter detector to nuclear recoils

*E. Aprile et al. (XENON100), Phys. Rev. D 88, 012006 (2013)*

### Analysis principle :

- AmBe spectrum with strength of  $(160 \pm 4)$  n/s measured by PTB in Germany
- Convert the deposited energy to S1 (scintillation) and S2 (ionization) signal using  $L_{\text{eff}}$ ,  $Q_y$ , thresholds, resolutions and acceptances from data
  - Reproduces both spectra and 2D parameter space

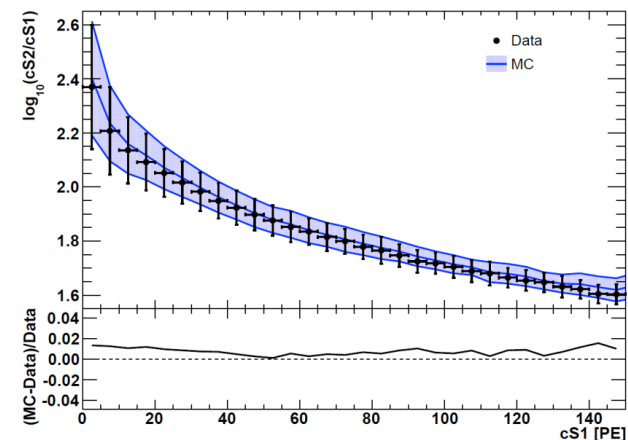

# XENON100 : Control on systematics with AmBe data

## Response of the XENON100 dark matter detector to nuclear recoils

*E. Aprile et al. (XENON100), Phys. Rev. D 88, 012006 (2013)*

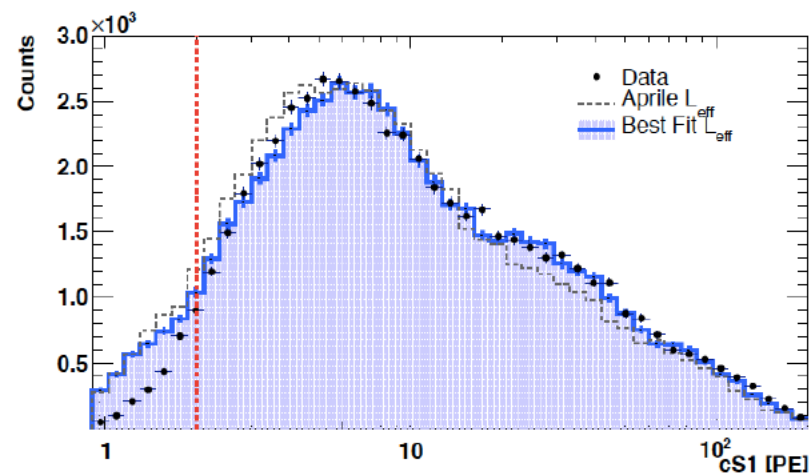

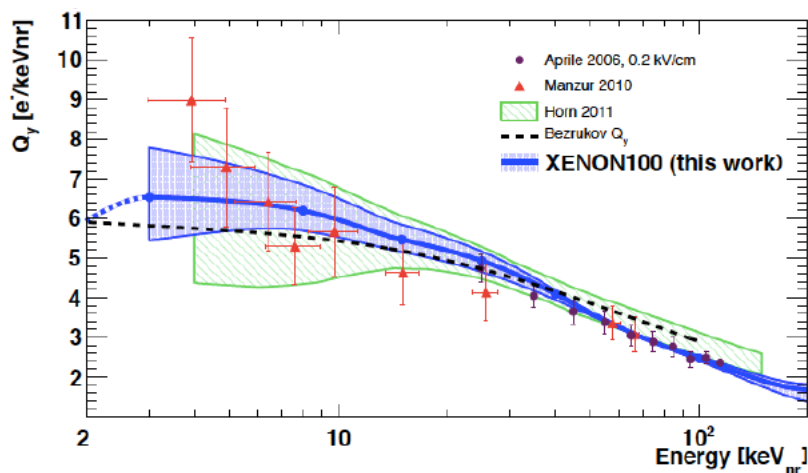

### Analysis principle :

- AmBe spectrum with strength of  $(160 \pm 4)$  n/s measured by PTB in Germany
- Convert the deposited energy to S1 (scintillation) and S2 (ionization) signal using  $L_{\text{eff}}$ ,  $Q_y$ , thresholds, resolutions and acceptances from data
  - Reproduces both spectra and 2D parameter space

**Step 1 :** Using  $L_{\text{eff}}$  from measurements, reproduce S2 spectrum

→ Obtaining the optimum  $Q_y$

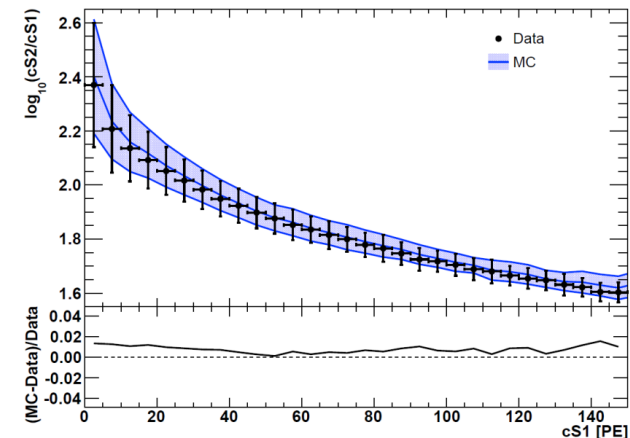

# XENON100 : Control on systematics with AmBe data

## Response of the XENON100 dark matter detector to nuclear recoils

*E. Aprile et al. (XENON100), Phys. Rev. D 88, 012006 (2013)*

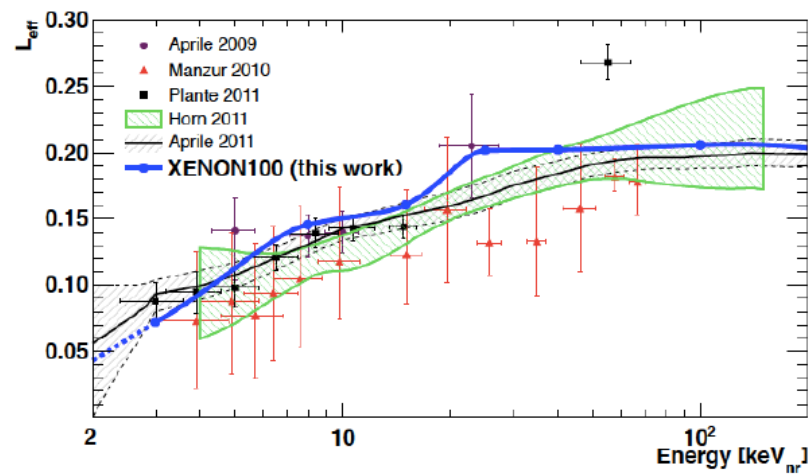

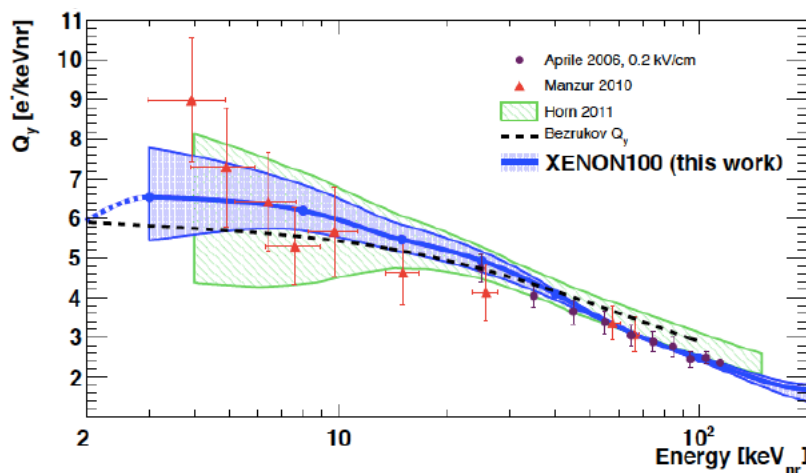

### Analysis principle :

- AmBe spectrum with strength of  $(160 \pm 4)$  n/s measured by PTB in Germany
- Convert the deposited energy to S1 (scintillation) and S2 (ionization) signal using  $L_{\text{eff}}$ ,  $Q_y$ , thresholds, resolutions and acceptances from data
  - Reproduces both spectra and 2D parameter space

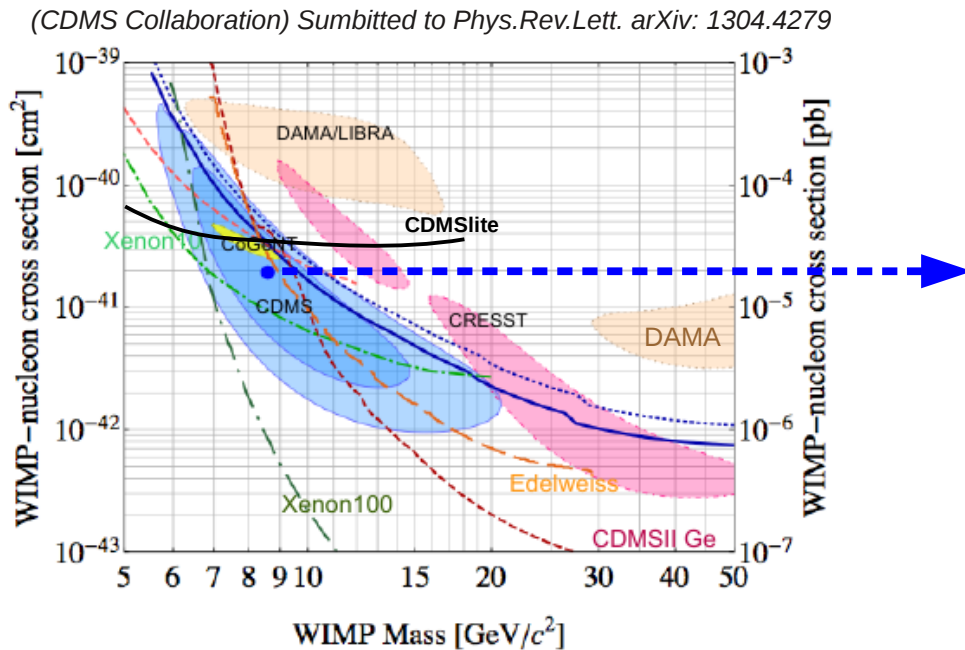

**Step 1 :** Using  $L_{\text{eff}}$  from measurements, reproduce S2 spectrum  
→ Obtaining the optimum  $Q_y$

**Step 2 :** Using the obtained  $Q_y$  reproduce S1 spectrum  
→ Obtaining a new  $L_{\text{eff}}$

Excellent agreement down to 2 PE ( $\sim 5$  keV<sub>nr</sub>) → Strengthens reliability in the XENON100 analysis

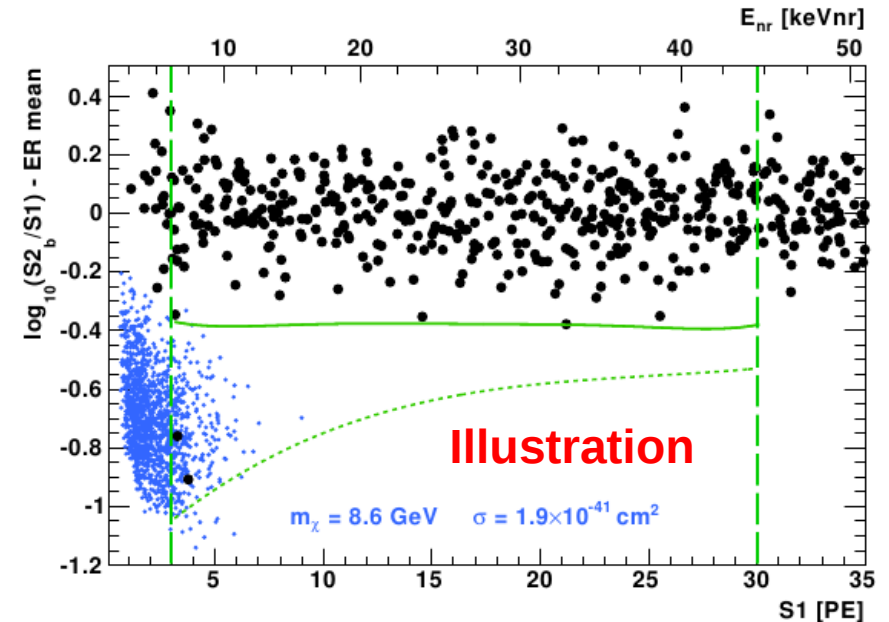

# XENON100 and CDMS : What if ?

- CDMS Best fit:  
 $1.9 \times 10^{-41} \text{ cm}^2$  @  $8.6 \text{ GeV}/c^2$  WIMP mass

PL analysis : 0.19% probability for the known-background-only hypothesis when tested against the alternative WIMP+background hypothesis

New results of CDMSlite (arXiv:1309.3259) cut away the upper part of the CDMS allowed region

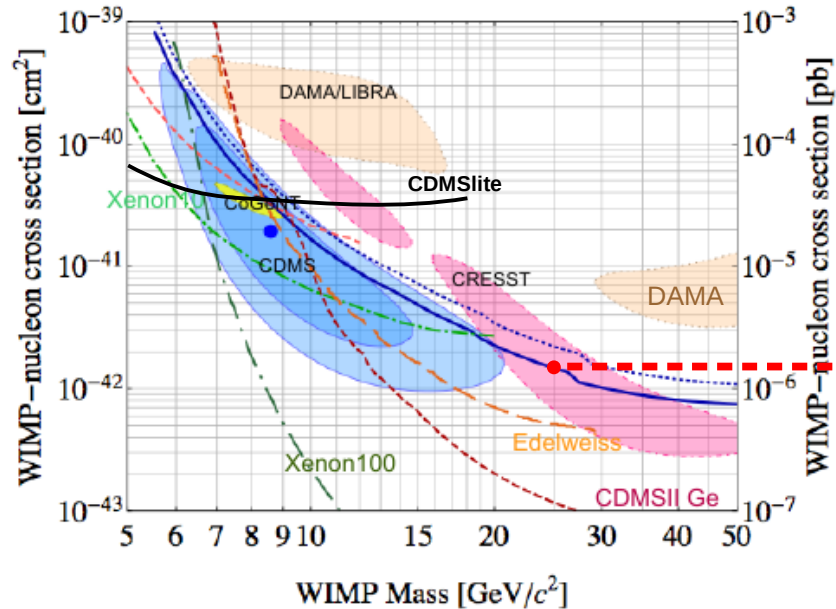

Black points :  
 → what XENON100 sees

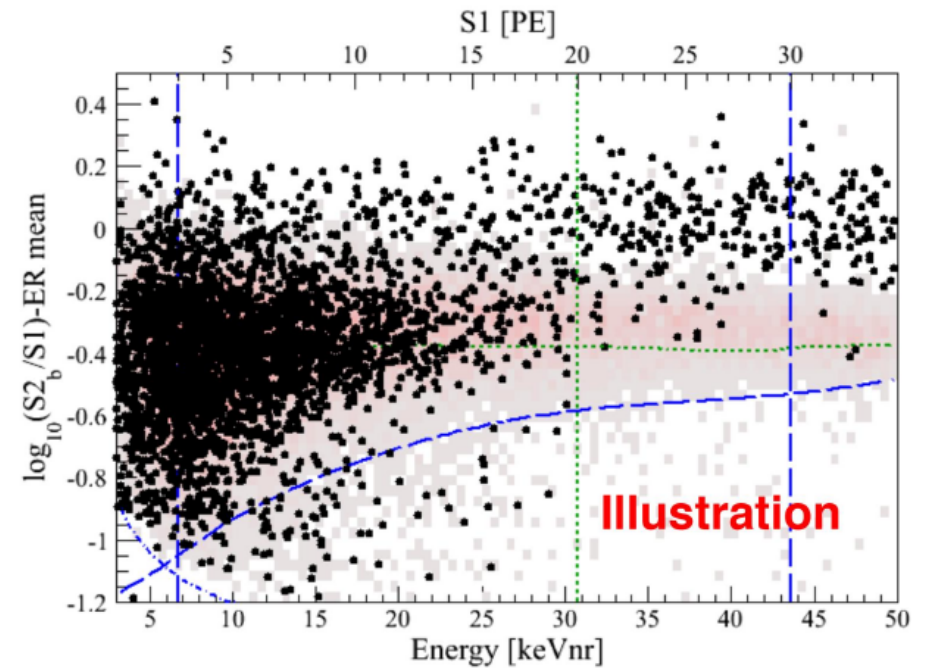

Plus blue points :  
 → what XENON100 would observe  
 (i.e., after correction on acceptances)  
 for the best fit point of CDMS

$223^{+303}_{-85}$  (sys) events would be observed

# XENON100 and CRESST : What if ?

- CRESST Best fit:  
M1 maximum:  
 $2.2 \times 10^{-42} \text{ cm}^2$  @  $21 \text{ GeV}/c^2$  WIMP mass

Black points :

- what XENON100 would observe (i.e., after correction on acceptances) at WIMP mass of  $25 \text{ GeV}/c^2$  and cross section  $1.6 \times 10^{-42} \text{ cm}^2$

$1409^{+53}_{-4}$  (sys) events would be observed

# XENON1T

**Detector :**

Dual phase TPC

# WIMP hunting...

# WIMP hunting : XENON1T and XENONnT

# XMASS-I

## Detector :

Single phase

Target : 100 kg LXe fiducial volume (835kg total)

## PMTs :

642 PMTs

Hamamatsu R-10789

Covering 60% of the surface

## Yield :

Very high ( $\sim 14$  PE/keV) and at low energy threshold ( $\sim 0.3$  keVee). Good for light mass WIMP search

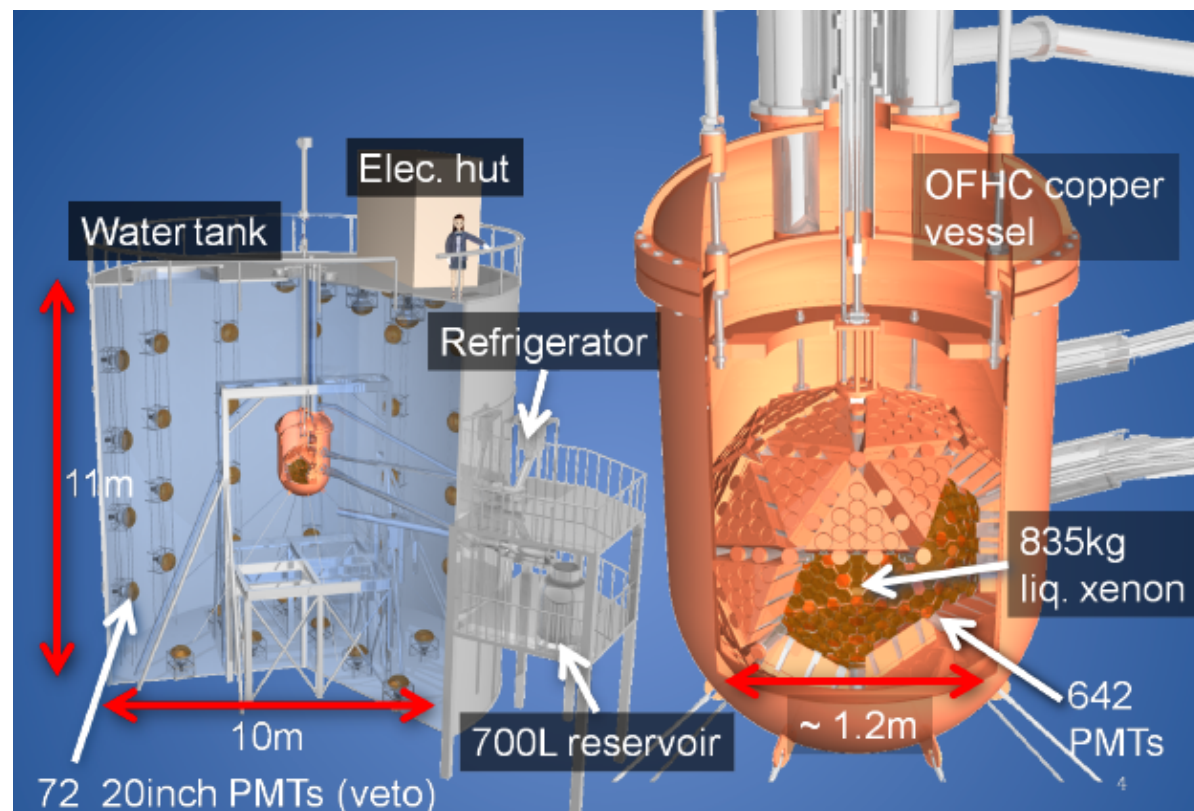

## Background :

Low background without particle ID

## Shielding :

Water tank as active muon veto

*J. Liu, Nucl.Phys.Proc.Suppl. 229-232 (2012) 564*

## Recent physics runs :

- Completed commissioning data-taking and analysis started
- 835kg times 6.70 days of live time

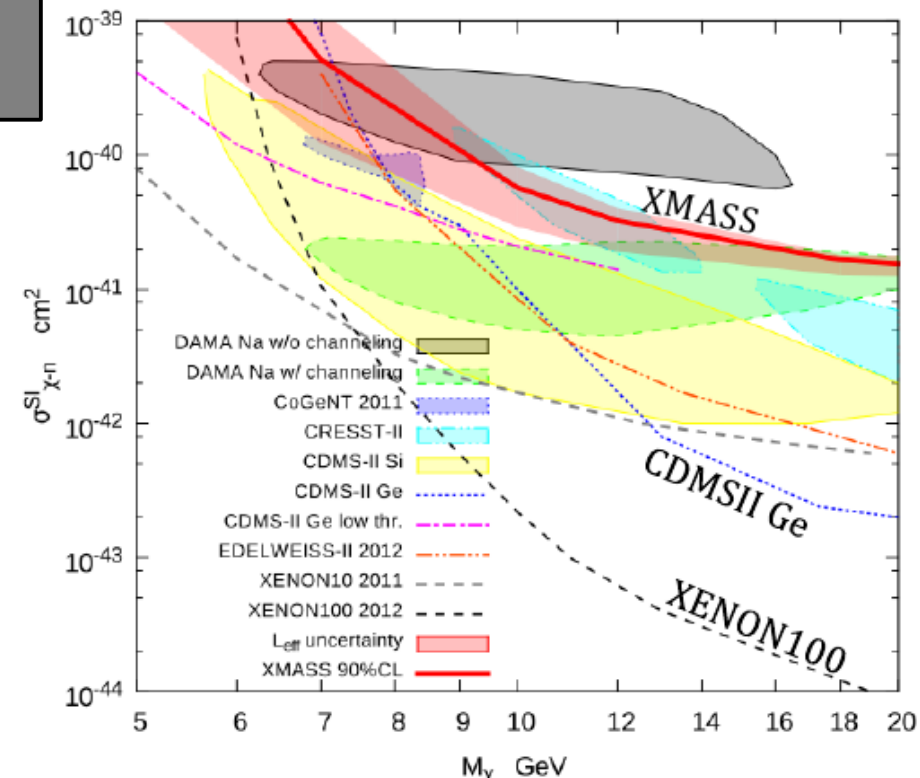

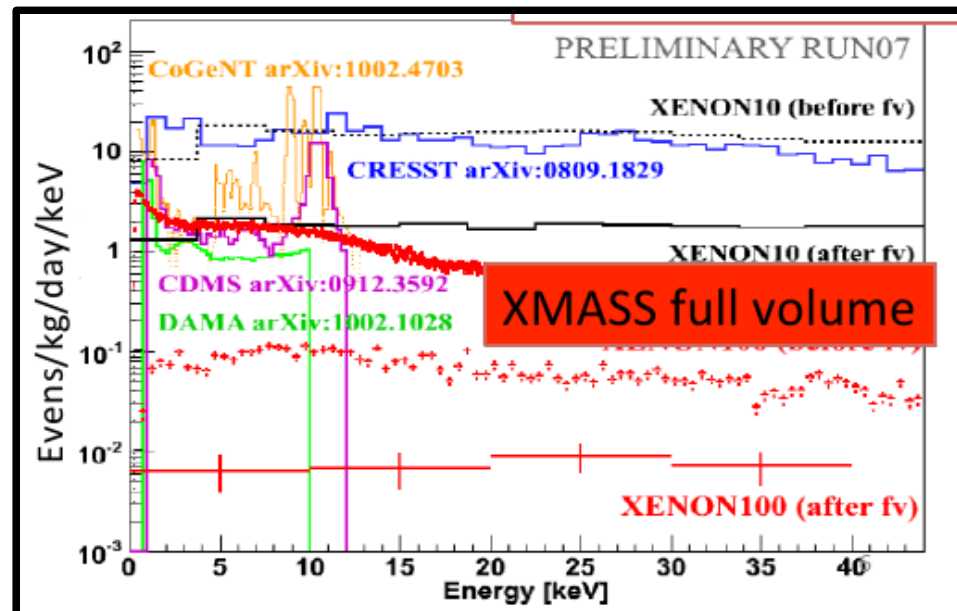

*K. Abe et al. (XMASS Collaboration), PLB 719 (2013) 78-82*

# XMASS-I : latest results

## Light mass WIMP search

*K. Abe et al. (XMASS Collaboration), PLB 719 (2013) 78-82*

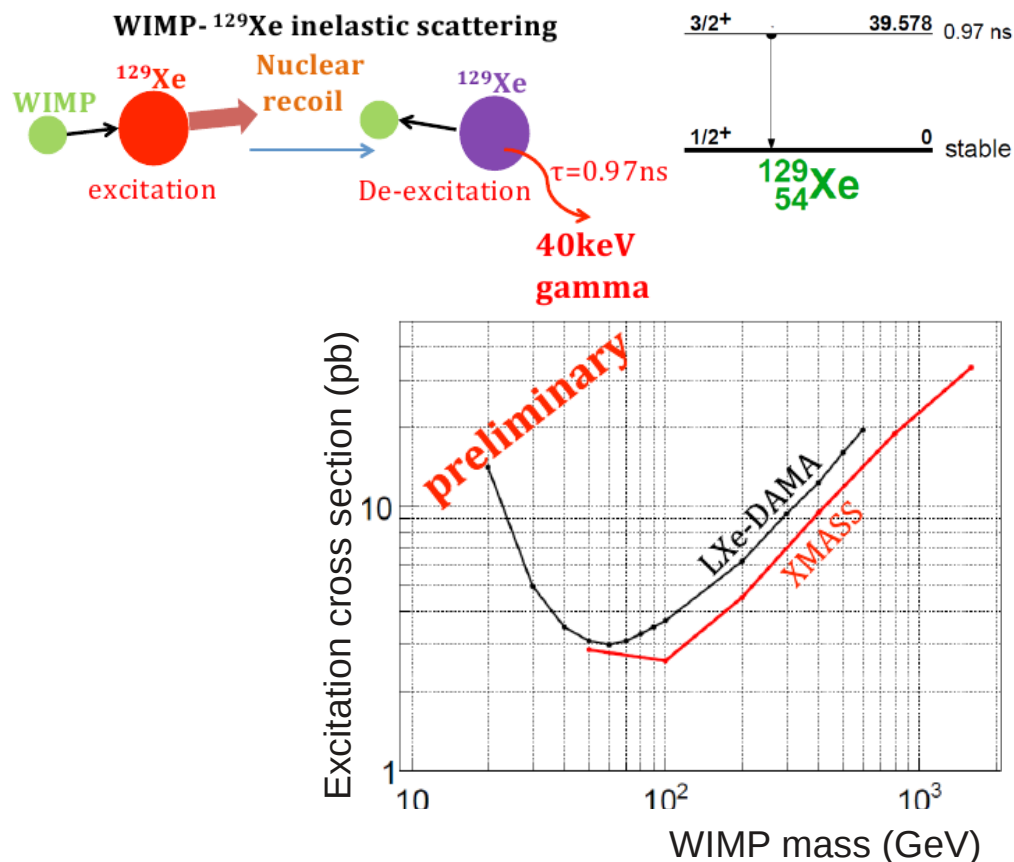

- 6.70 live days collected with low trigger threshold
- Whole volume (835kg) used
- The result excludes part of the parameter space favored by other measurements
- After the refurbishment, they will expect 1 to 2 orders of magnitude improvement

# XMASS-I : latest results

## WIMP- $^{129}\text{Xe}$ inelastic scattering

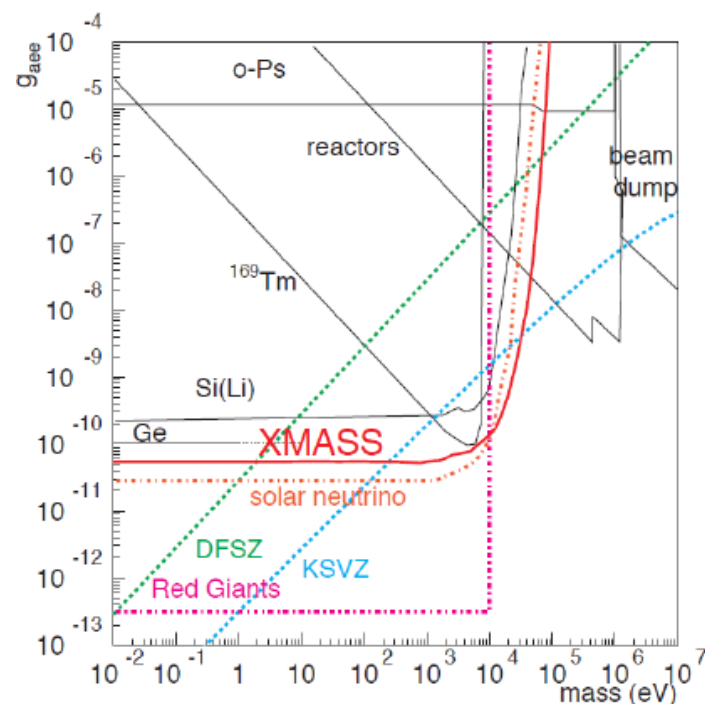

- 6.70 live days collected with low trigger threshold
- $R < 15\text{cm}$
- Still a preliminary study (presented at CYGNUS 2013@Toyama)

## Solar axion search

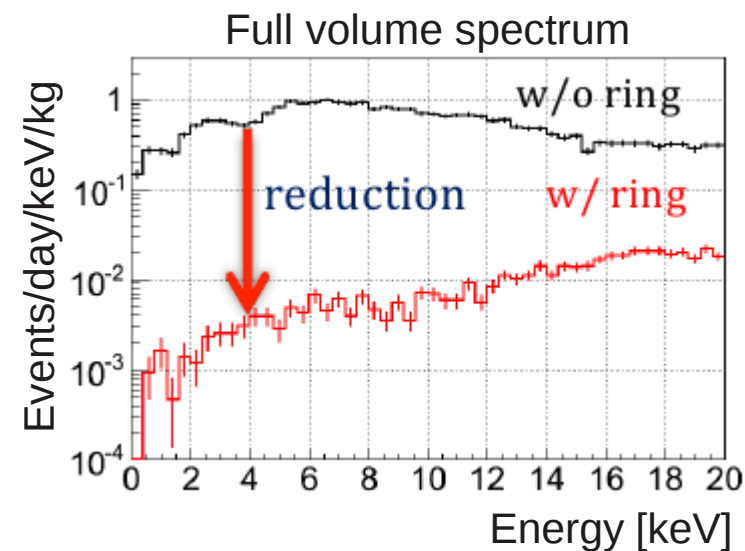

ArXiv:1212.6153, Accepted for publication in PLB

- 6.70 live days collected with low trigger threshold
- Whole volume (835kg) used
- mass  $< 1\text{ keV}$  is  $|g_{\text{Ae}}| < 5.4 \times 10^{-11}$  (90% C.L.)

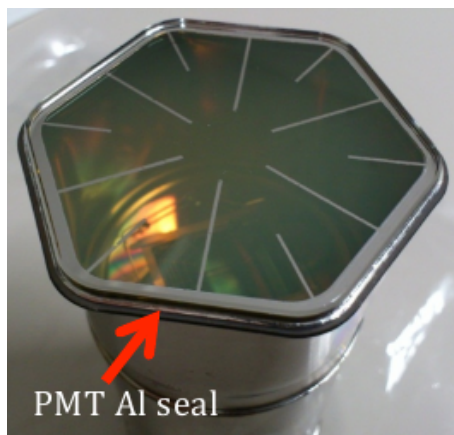

# XMASS-I : refurbishment

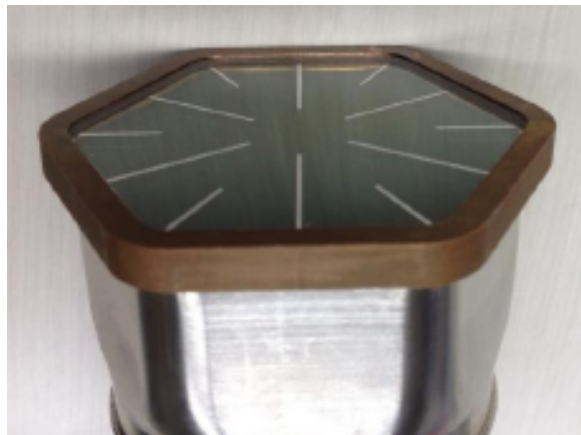

- XMASS-I discovered an unexpected source of background in the aluminum seal of PMTs
  - Background  $\sim 100$  times larger than expected
- A campaign of refurbishment started. Purposes are:
  - Confirmation of background reduction by shielding of scintillation light originated from PMT aluminum by a copper ring
  - Also to demonstrate the reduction of  $^{210}\text{Pb}$  (second largest background component) with electropolishing and special clean environment
- The refurbishment should be completed before the end of 2013

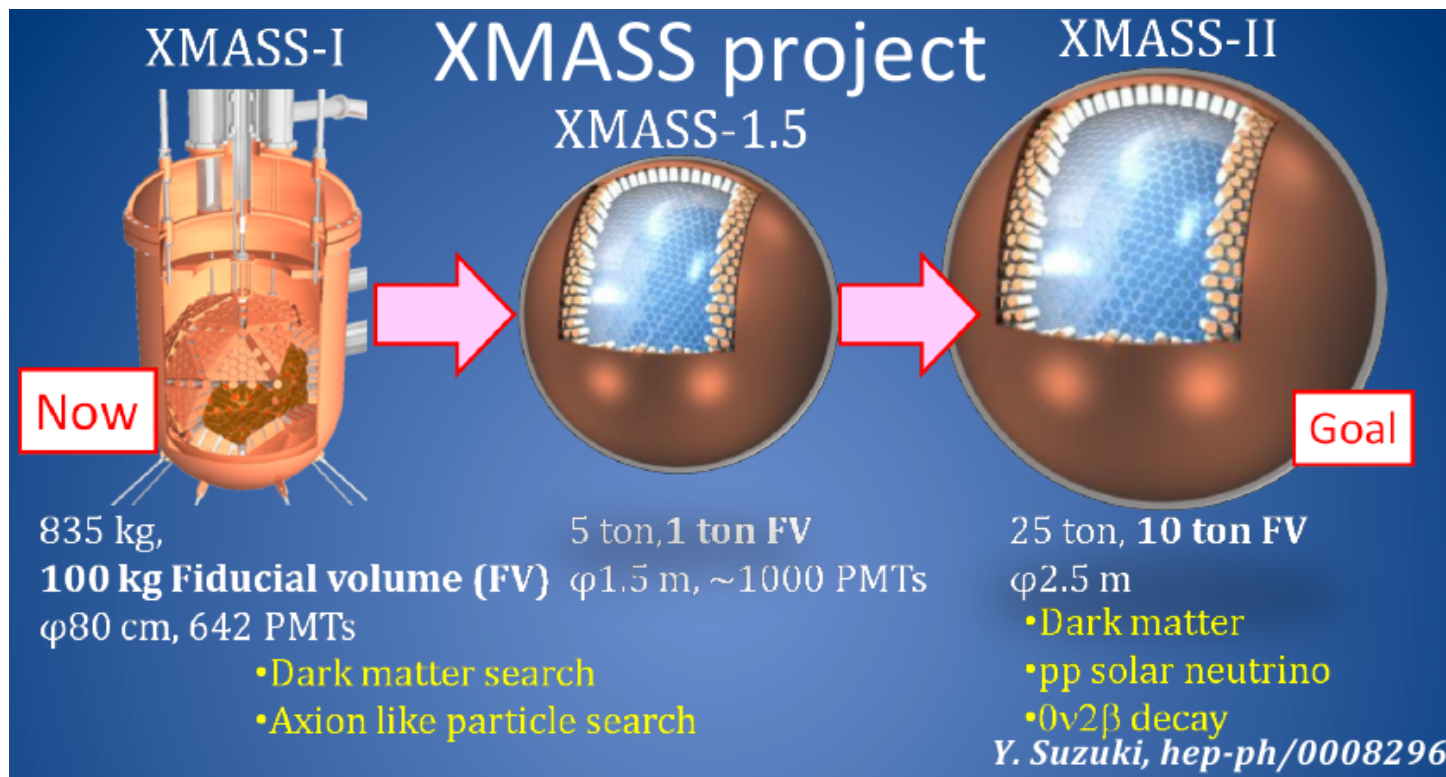

Before the installation of the ring

After the installation of the ring

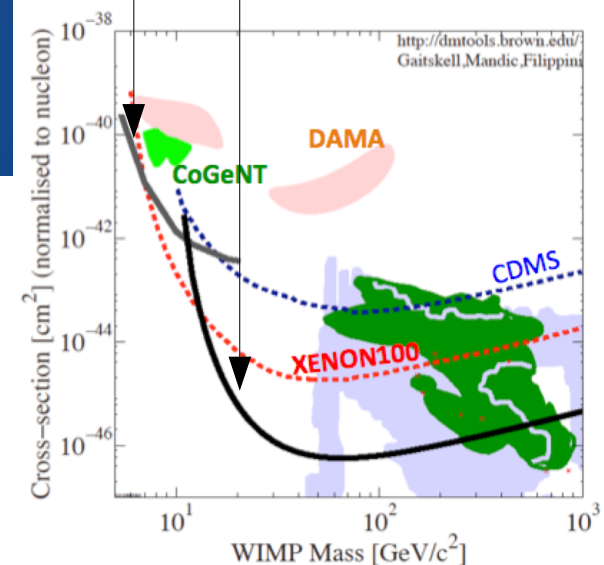

# XMASS-1.5 and future

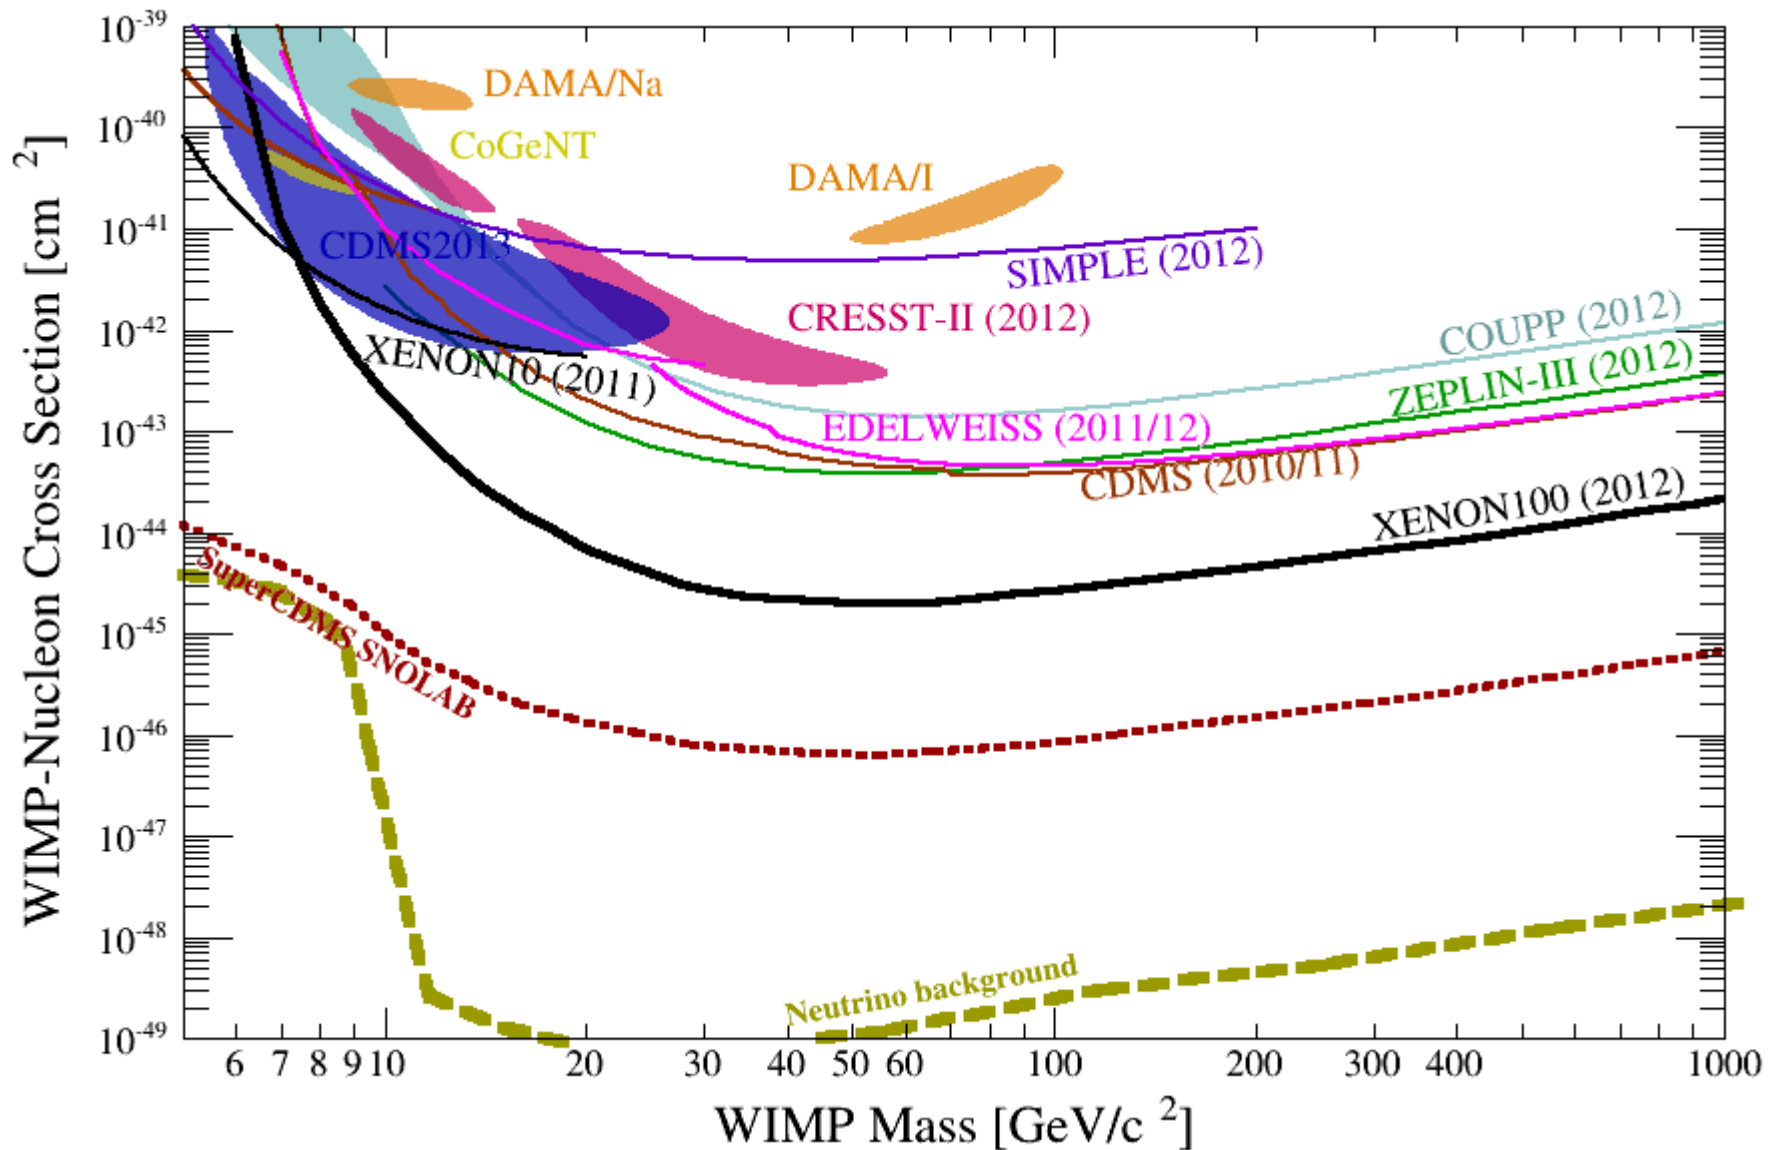

- Final goal of the program is a 25 ton detector: XMASS-II
- Next step: XMASS-1.5
- New PMTs will be developed without aluminum

XMASS-1.5 full volume

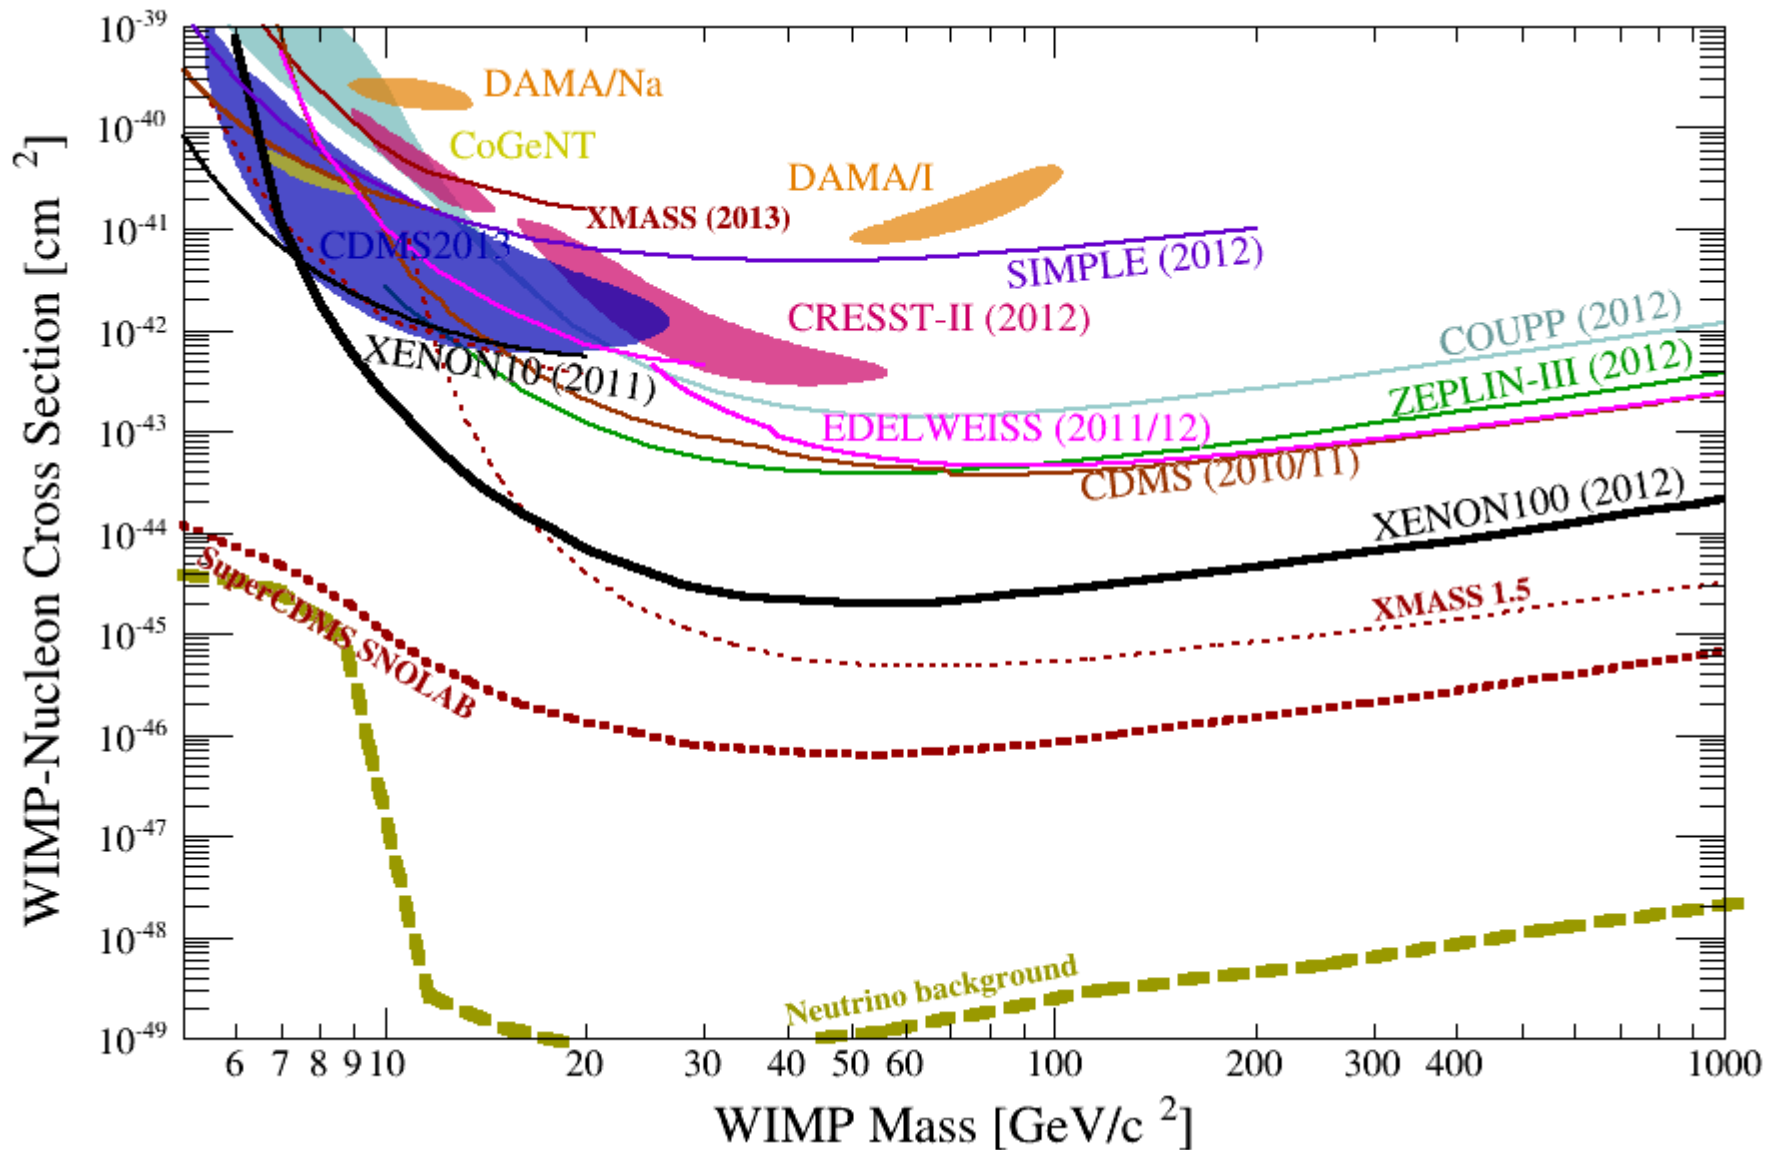

XMASS-1.5, 2keV threshold, 1 year

DI Water tank, dissolved  $O_2 < 0.5$  ppb

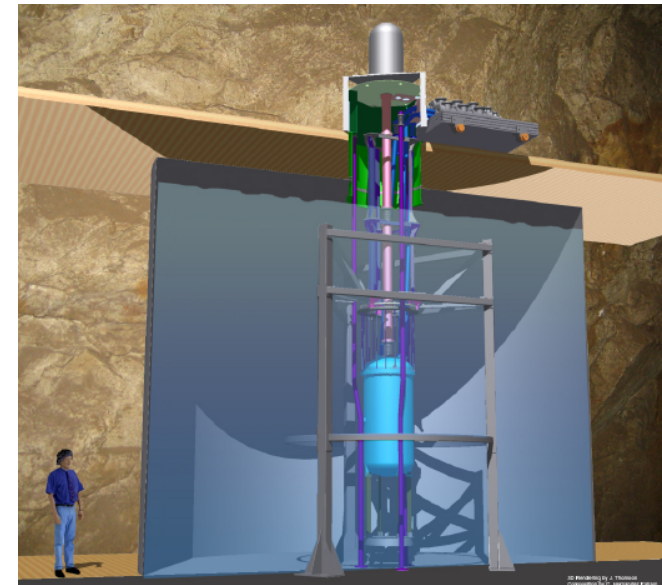

**Timeline :**

- LUX 0.1 (2007-2009)
- LUX Surface running (2010-2012)
- Underground transport (2012)
- LUX Underground run (2012-2013) – Results public in October 30th!
- Year-long science run (2014-2015)

In surface (2011)

Underground

# LUX : progresses and waiting for the announcement

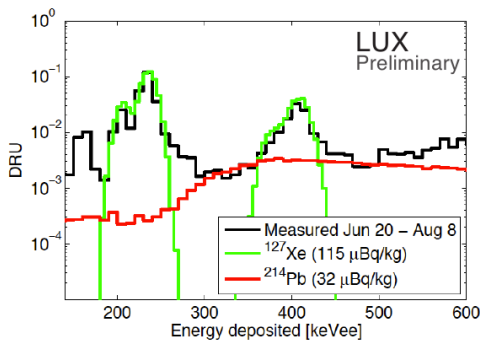

## Surface run

*D.S. Akerib (LUX Collaboration), Astropart. Phys. 45 (2013) 34–43*

- Measured light collection efficiency  $\sim 8\text{phe/keVee}$
- 6% energy resolution (@662keV,  $^{137}\text{Cs}$ )
- event reconstruction  $\sim 7\text{mm}$

## Underground

- Xe circulation system  
→ electron mean free path  $> 100\text{ cm}$  (March 2013)
- $^{85}\text{Kr}$  removal. Gas chromatography  
→ 4ppt achieved *arXiv:1103.2714v3*
- $^{222}\text{Rn}$  decay chain, primarily  $^{214}\text{Pb}$   
→ upper limit of  $< 0.23\text{ mDRU}_{\text{ee}}$  or 0.1 ER event / day (fiducial)

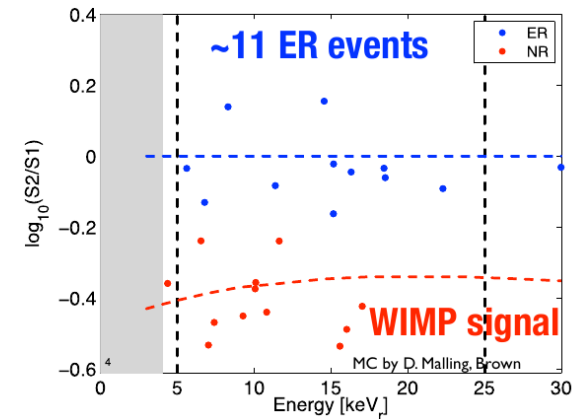

- LUX has been operating underground since spring 2013
- stable detector operation achieved
- first WIMP search result announced on Oct 30

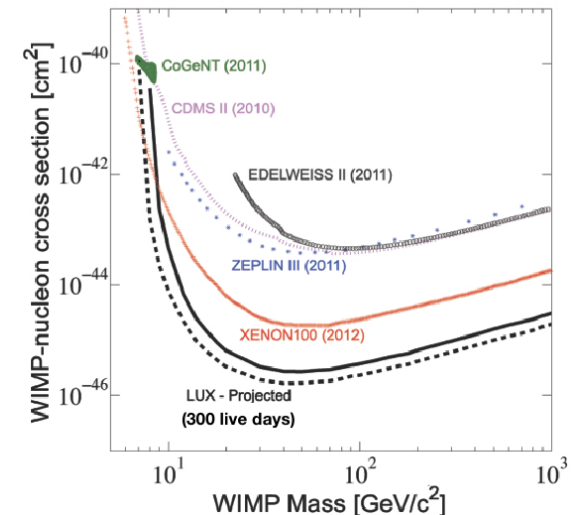

*Plots presented by M. Horn, WIN2013*

## Expectations (MC):

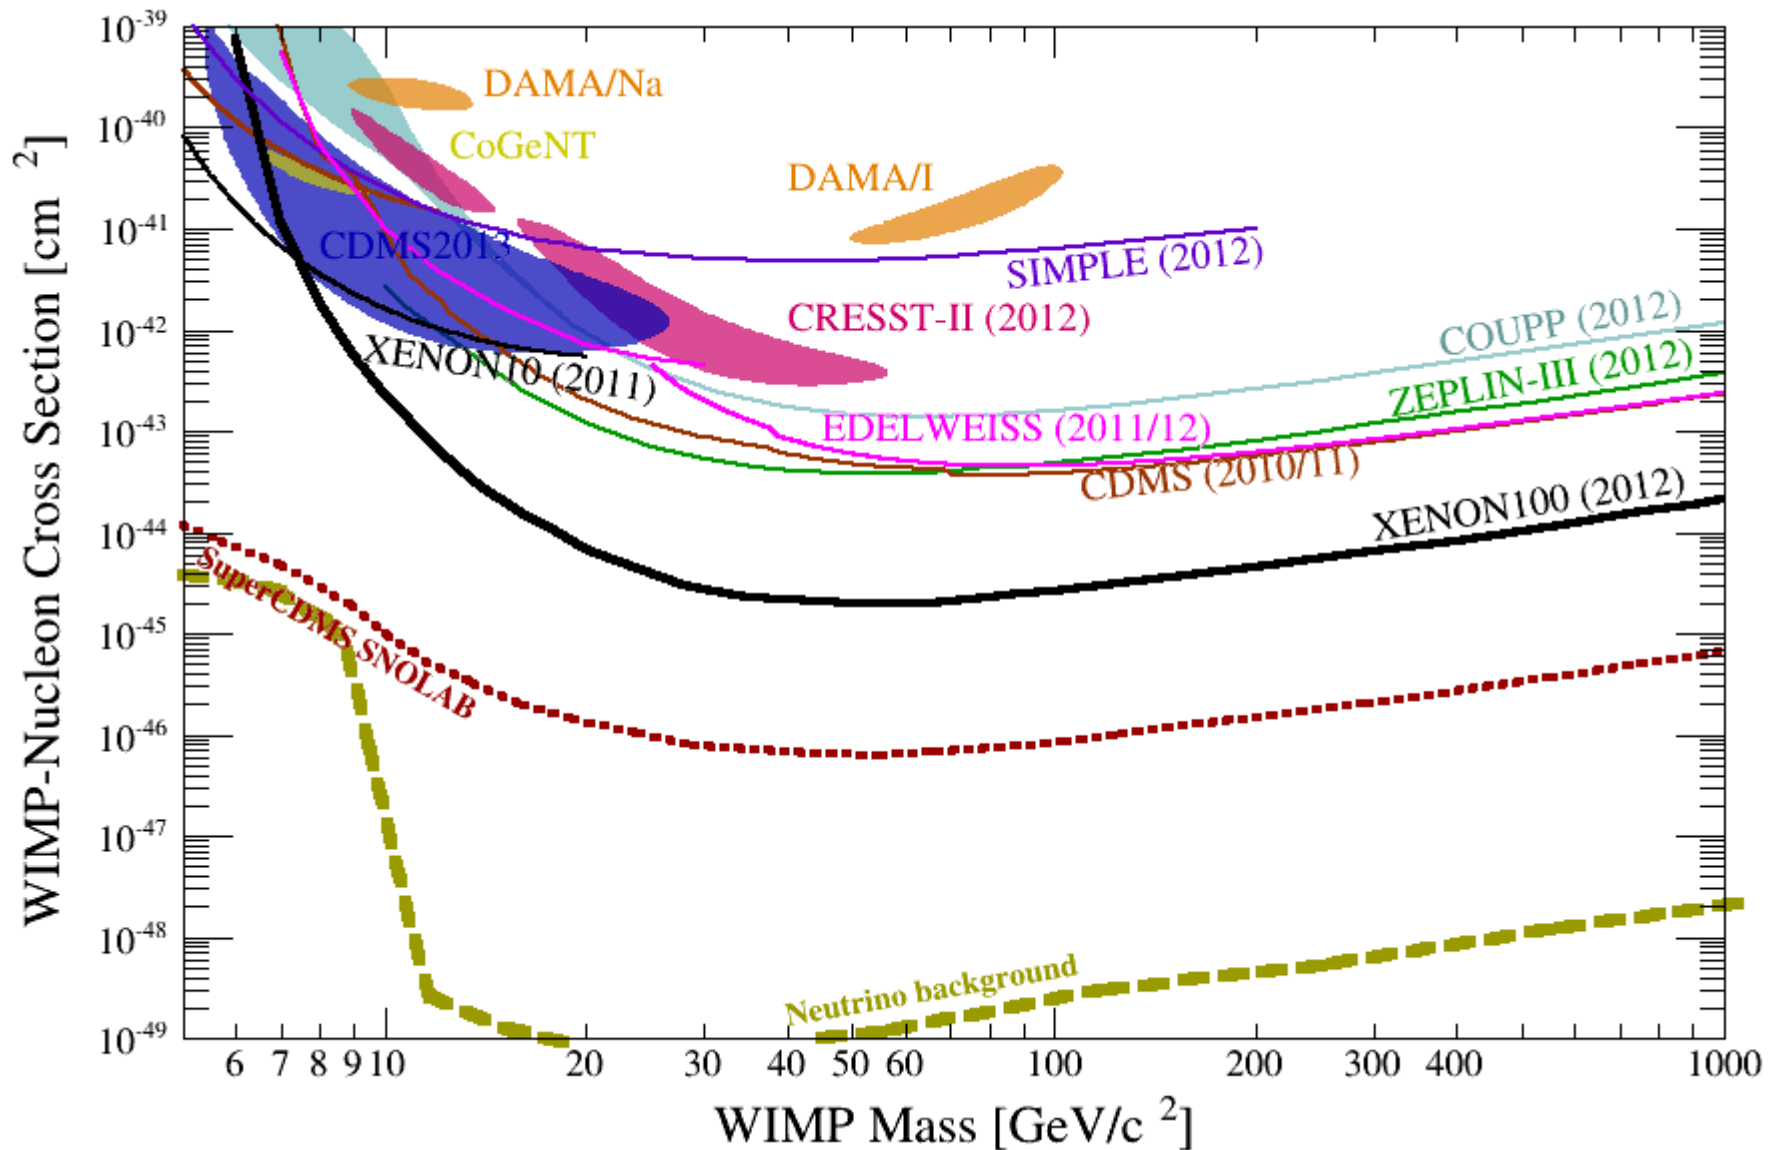

With 40 live days  $\rightarrow \sim 11\text{ ER events}$

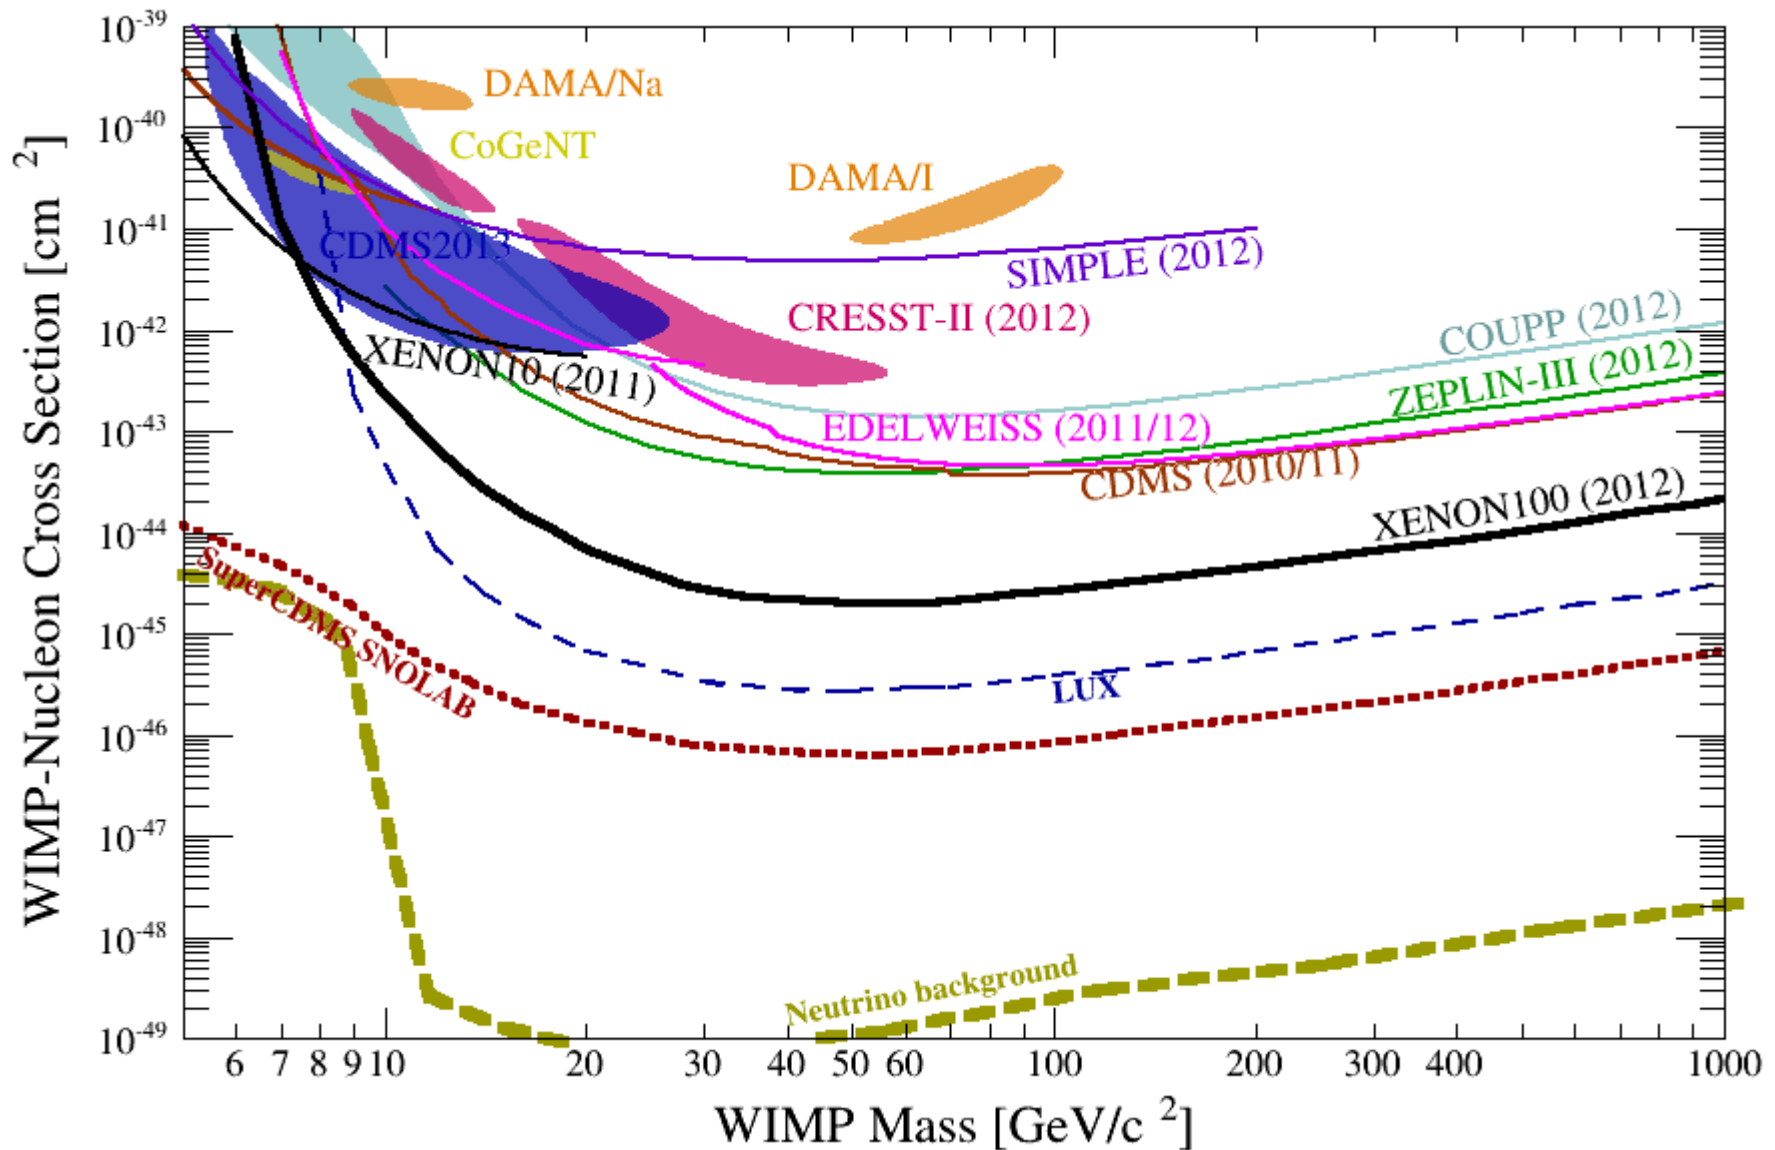

## Projections

# WIMP hunting...

# WIMP hunting : LUX

# DEAP-3600

## Detector :

Single phase

Target : 3.6 ton LAr (1ton fiducial)

## PMTs :

255 “warm” PMTs

Hamamatsu R-5912 8"

(32% QE, 75% coverage)

## Cryogenic containment :

Steel shell and a monolithic acrylic vessel

## Shielding :

8 m water shield

50 cm acrylic

Background dominated by (alpha, n) neutrons from PMT glass

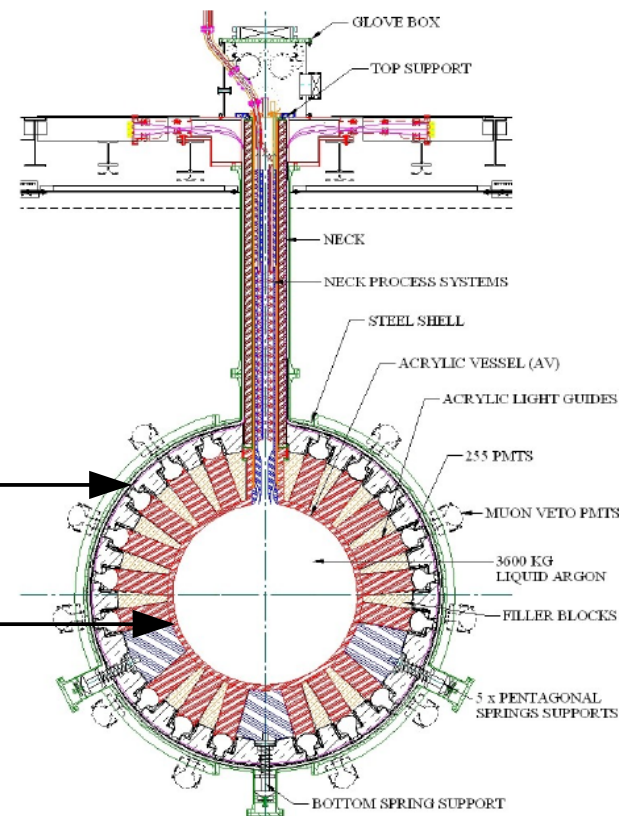

## Timeline :

- DEAP-0 (R&D)
- DEAP-1 (2008) : 7kg LAr, 2 PMTs
- DEAP-3600 (from 2012) : 3600 kg cooldown in January 2014, plus 2 months of commissioning
- Future: 50 tons

Steel shell in the water tank

Acrylic shell

# MiniCLEAN

## Detector :

Single phase

Target : 500 kg LAr (150 fiducial), but also LNe

## PMTs :

92 optical cassettes with PMTs

## Yield :

3.5 PE/keV in neon

(arXiv:1111.3260)

## Cryogenic containment :

Stainless steel

## Shielding :

8 m water shield with muon veto with 48 PMTs

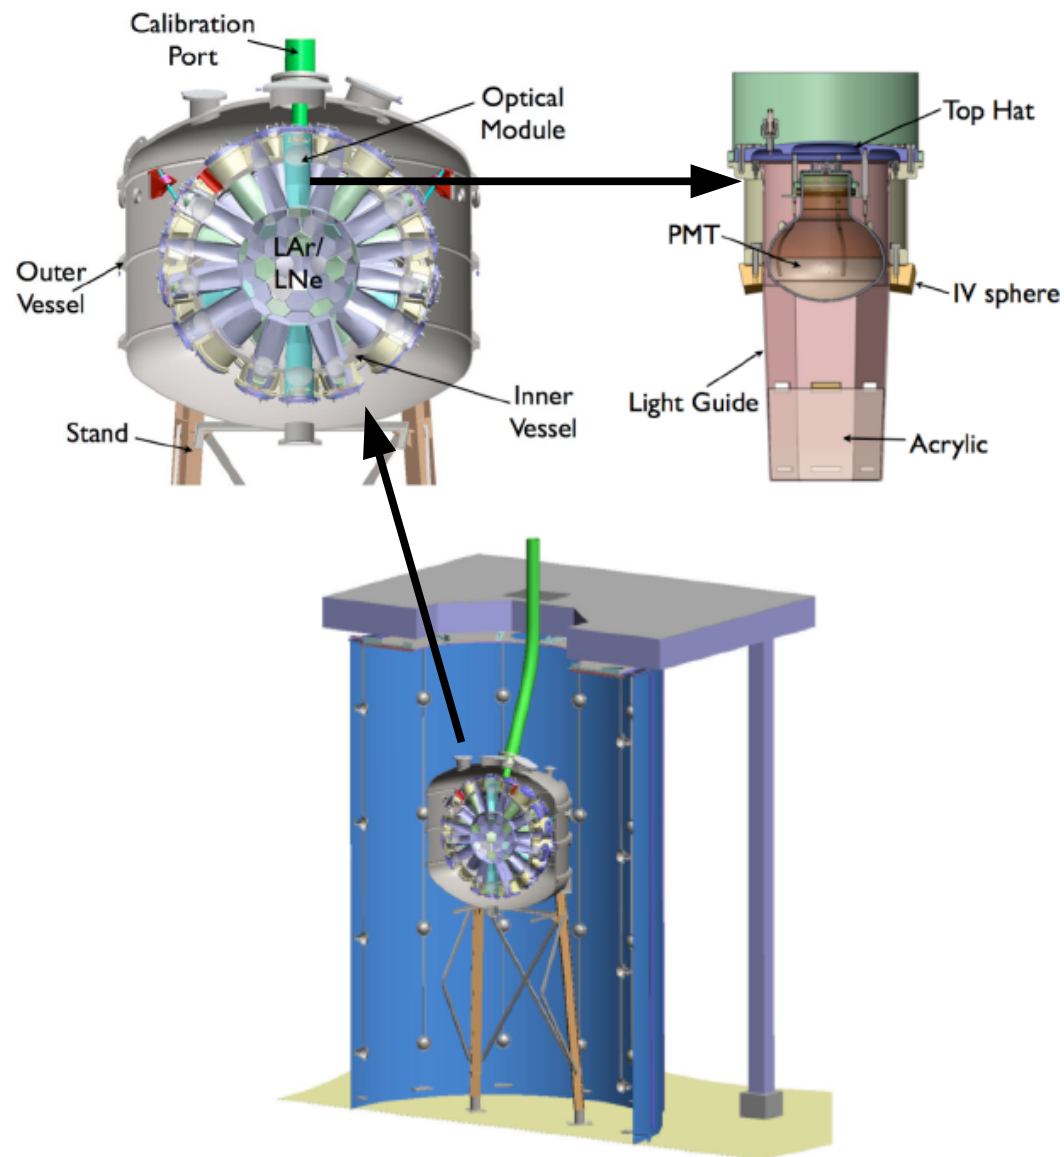

10 cm acrylic + 20 cm cryogen

## Strategy :

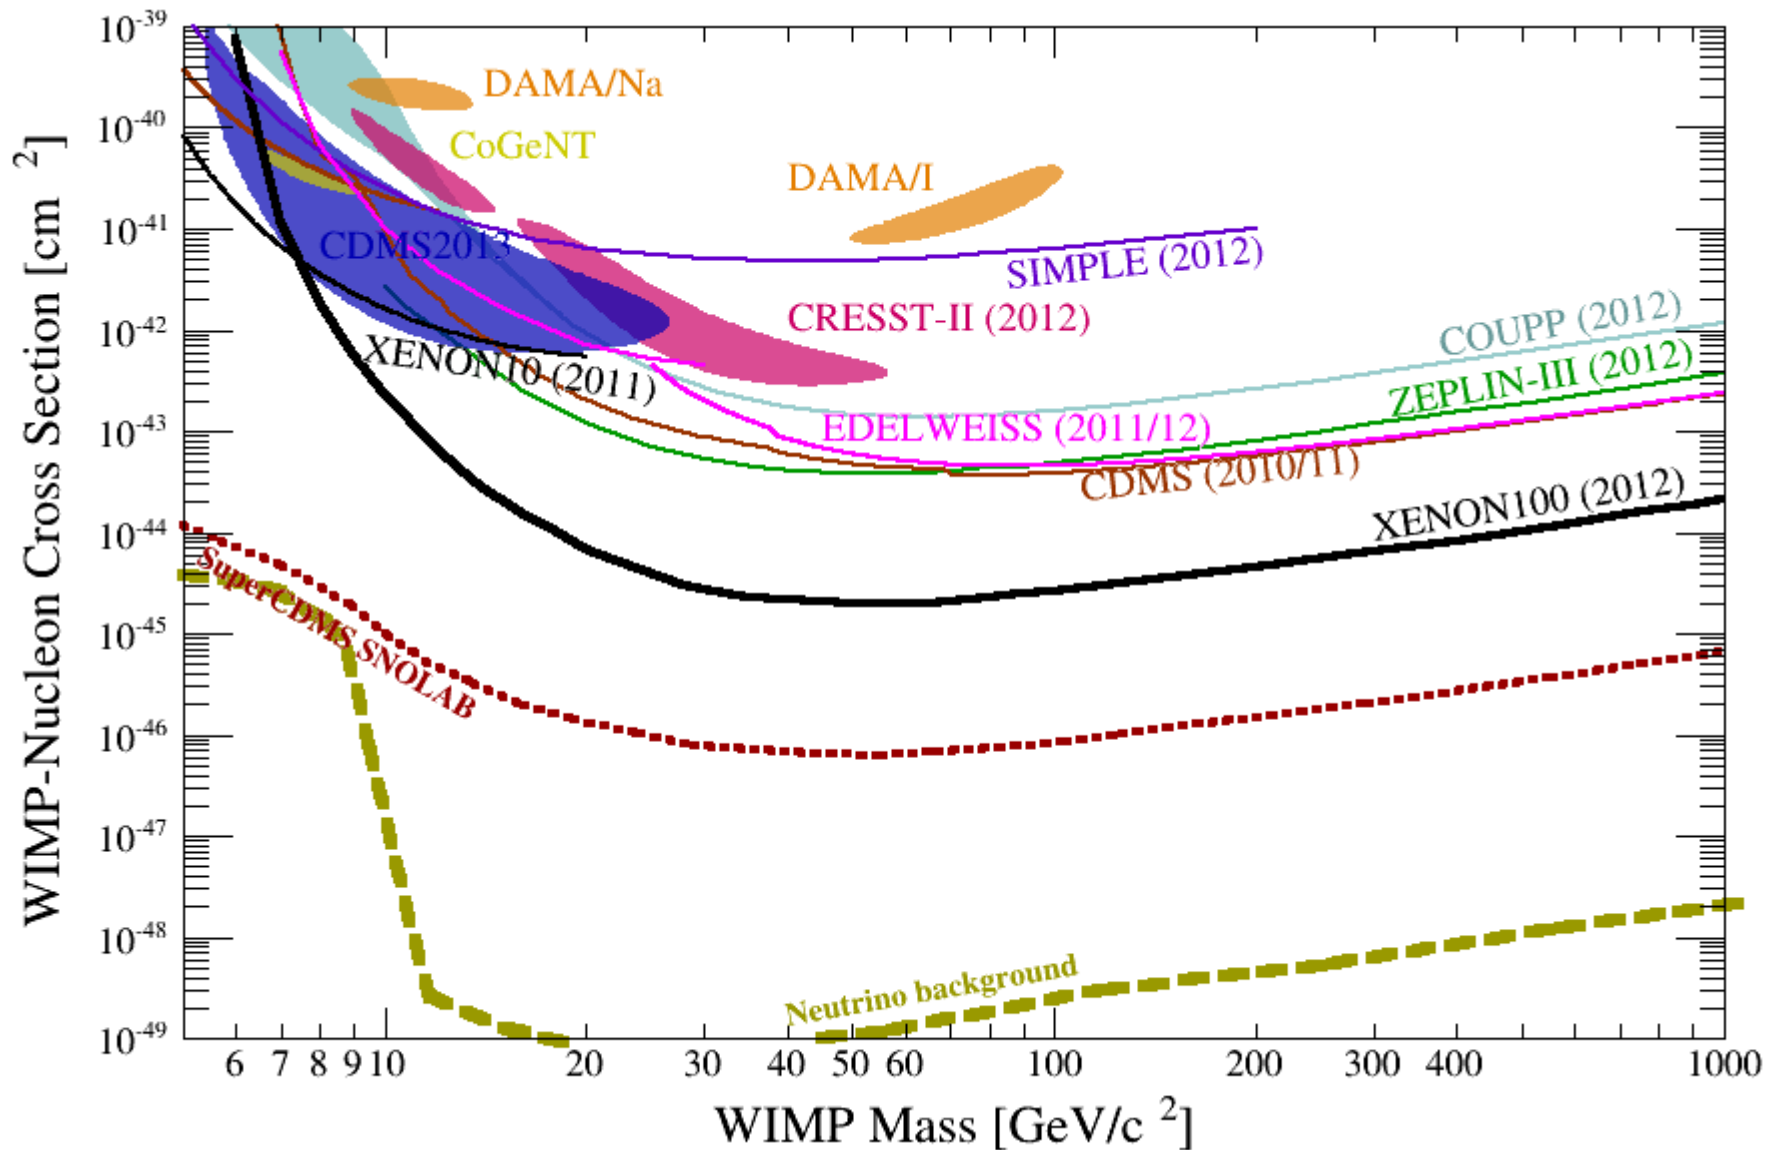

PSD with Ar. If signal, then using enriched  $^{39}\text{Ar}$  to check for an increase of rate. Finally, run with LNe

## Timeline :

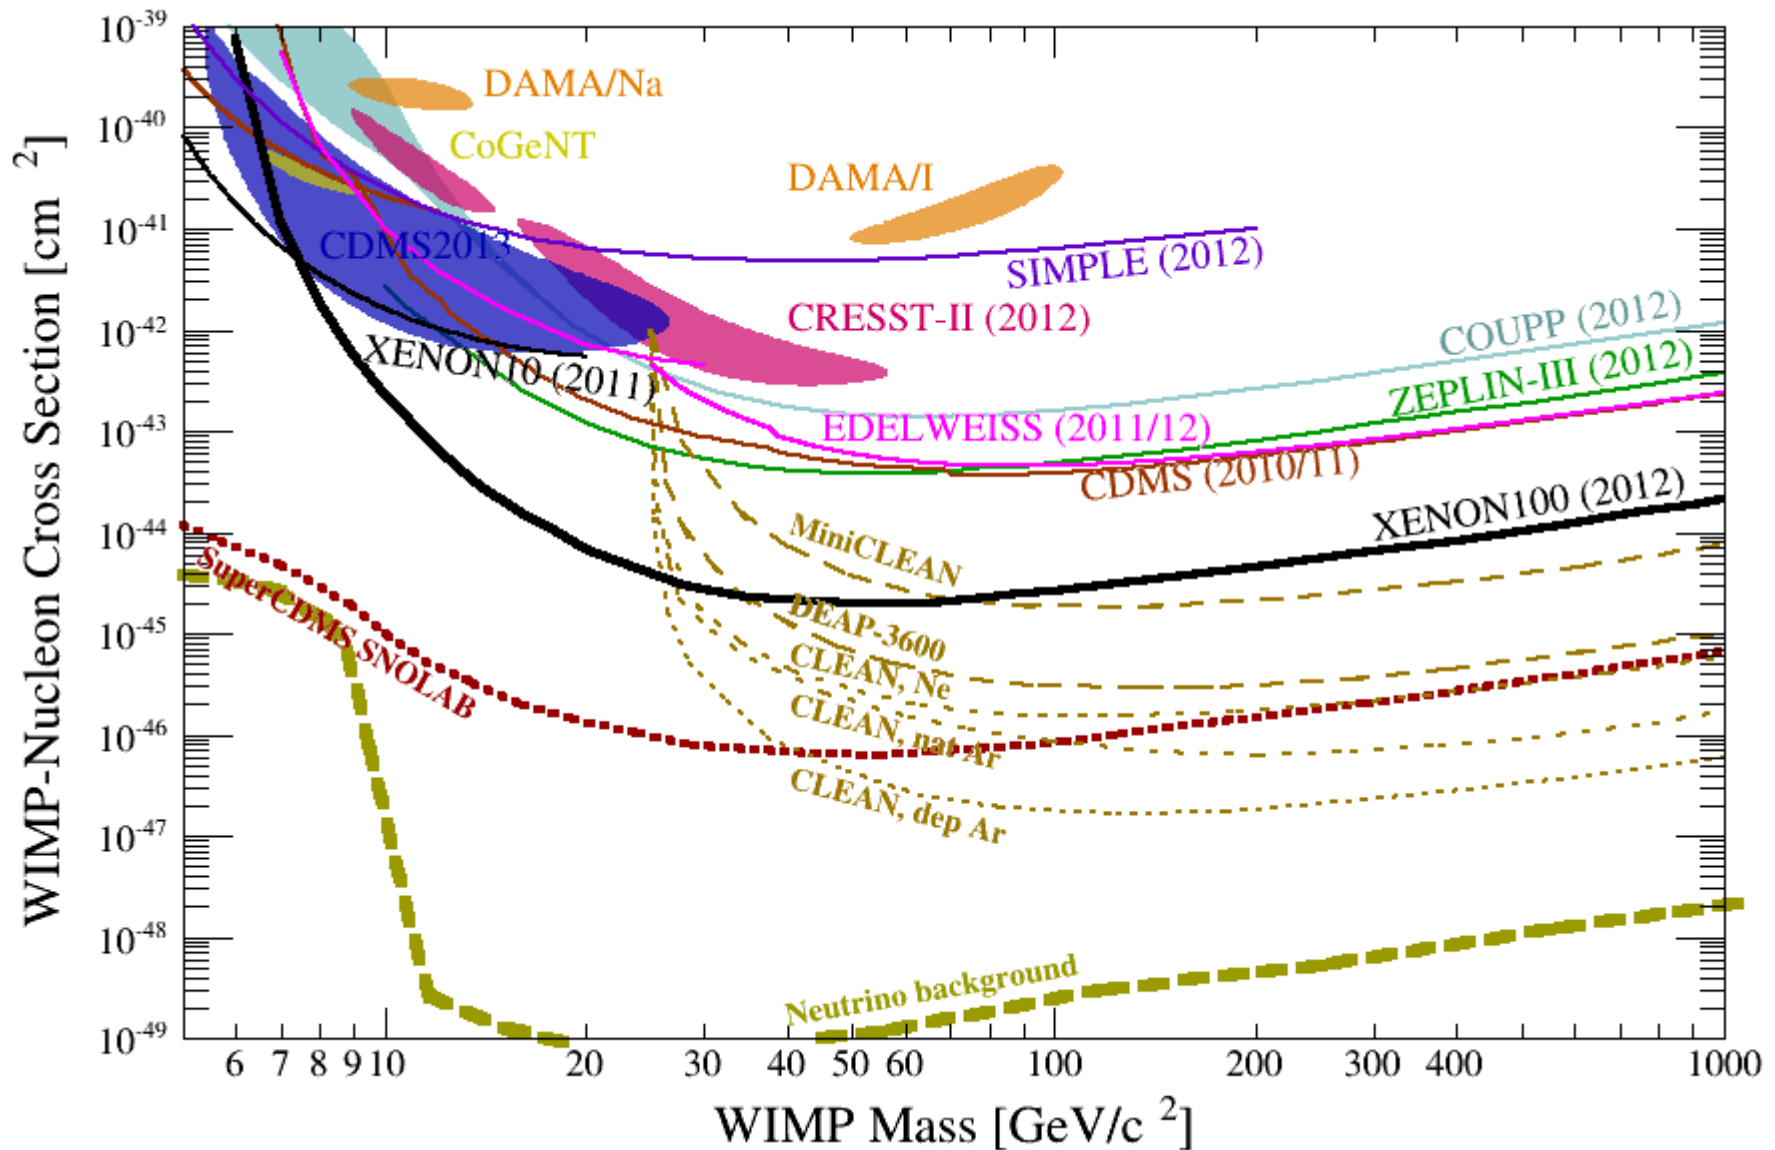

- picoCLEAN (R&D)
- microCLEAN : 4kg Lar or LNe, 2 PMTs (tests at Yale)
- MiniCLEAN (from 2011)
- Future: 50 tons

# WIMP hunting...

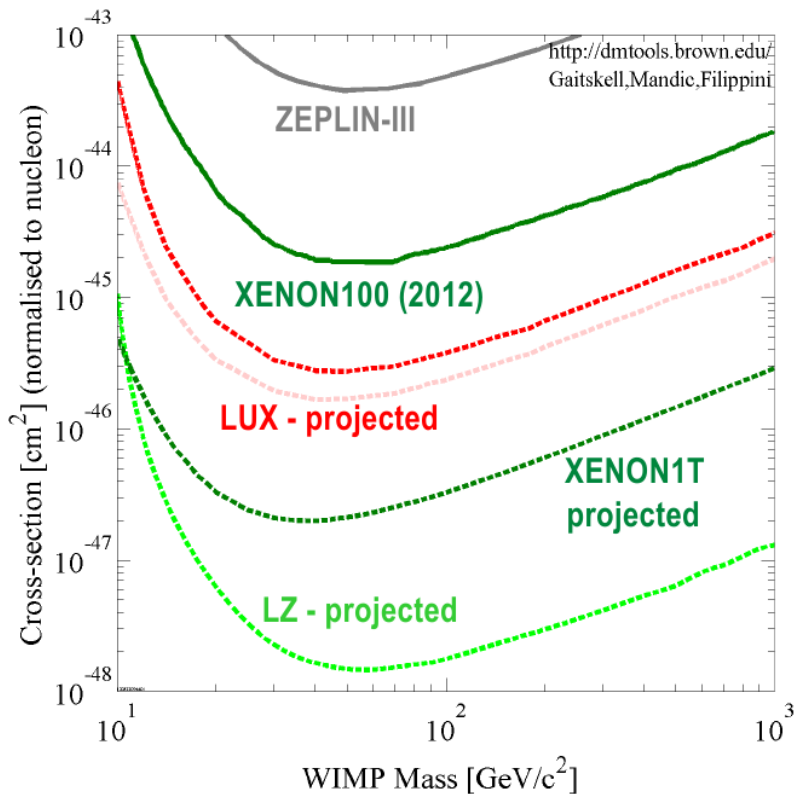

# WIMP hunting : DEAP/CLEAN

# Ultimate WIMP facilities: DARWIN, LZ, ...

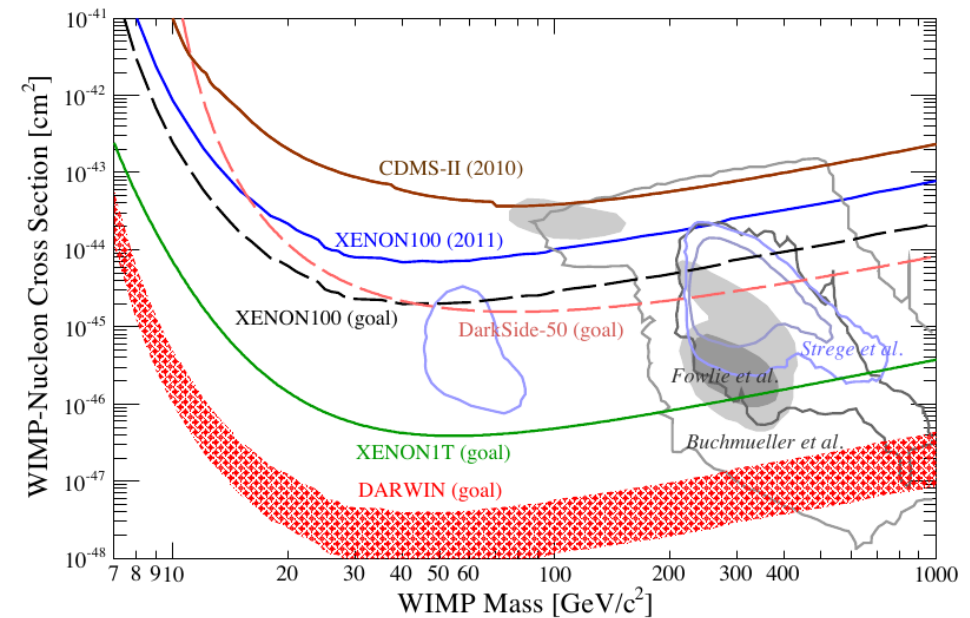

## Beyond LUX : LZ = LUX + ZEPLIN

- 7 tons of LXe (6tons fiducial)
- 500 3" PMTs (@1 mBq level)
- liquid scintillator veto
- construction 2015 - 2016
- operation 2016 – 2019...

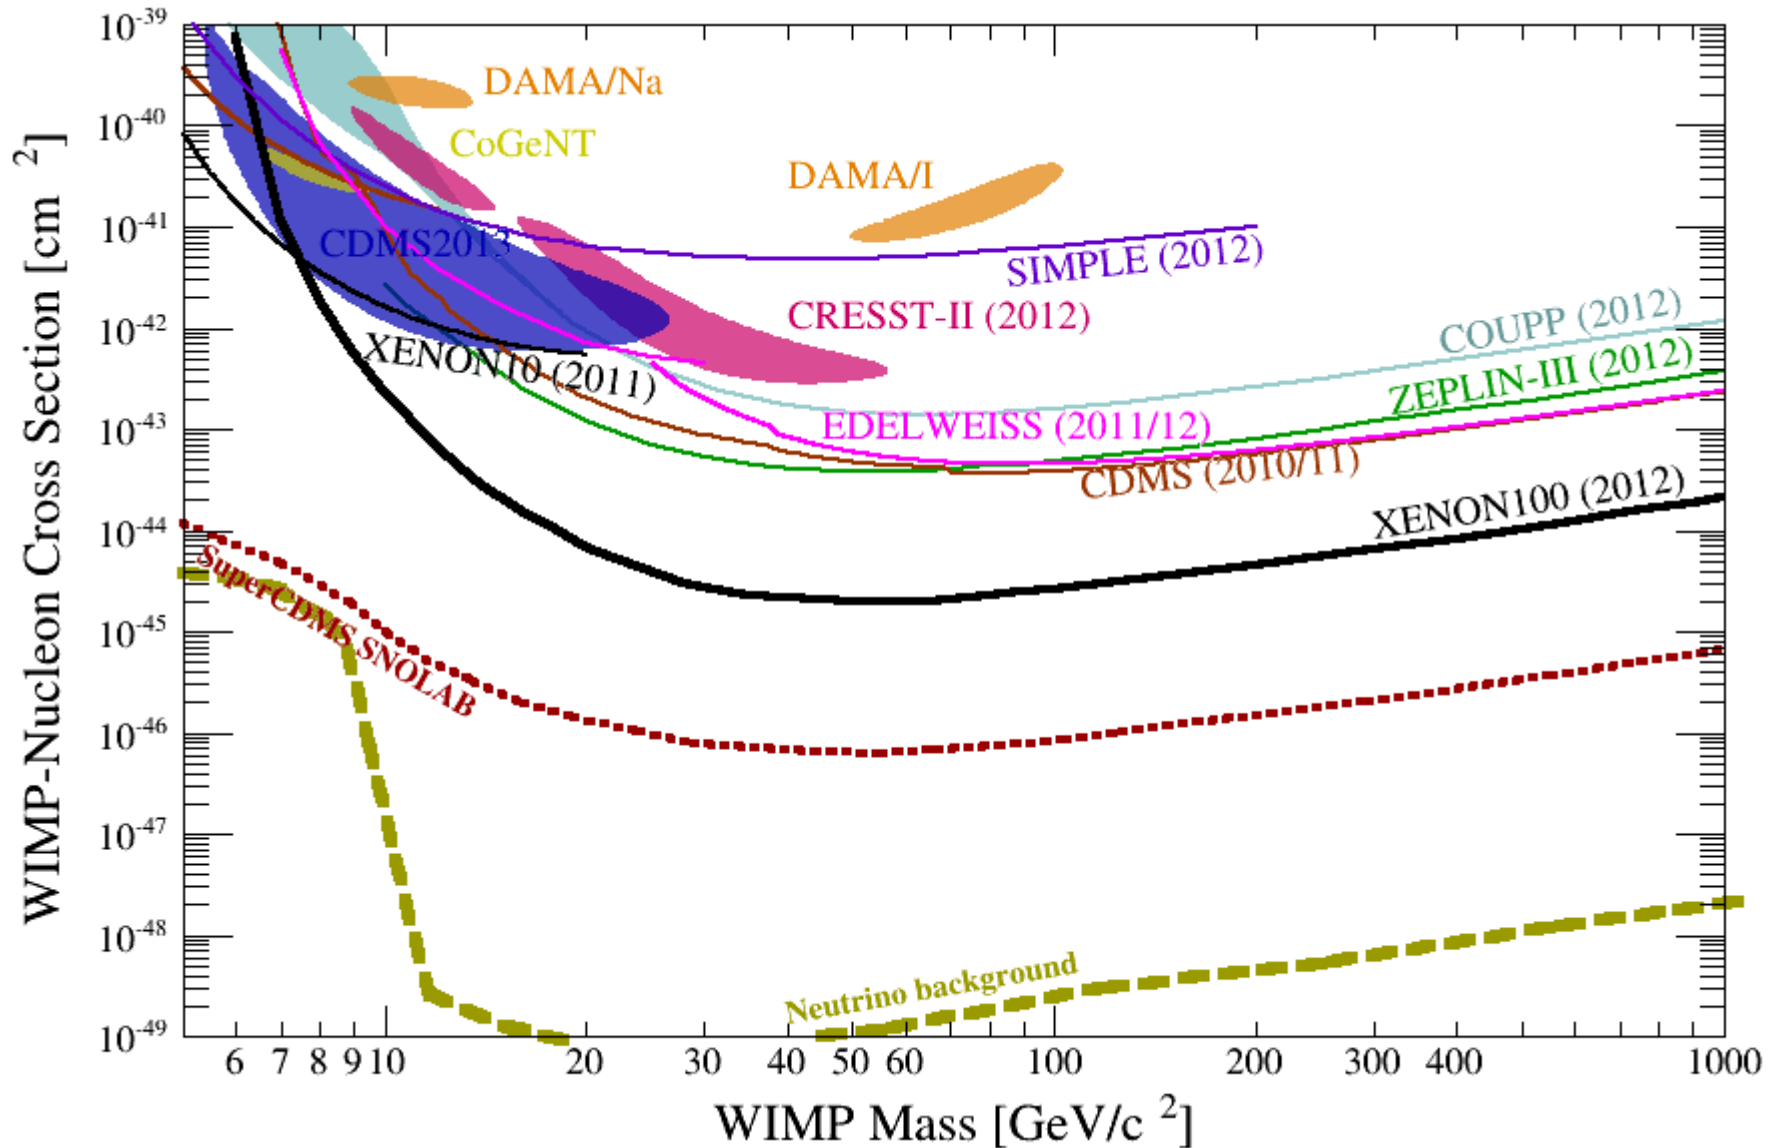

## Beyond XENON and DarkSide : DARWIN

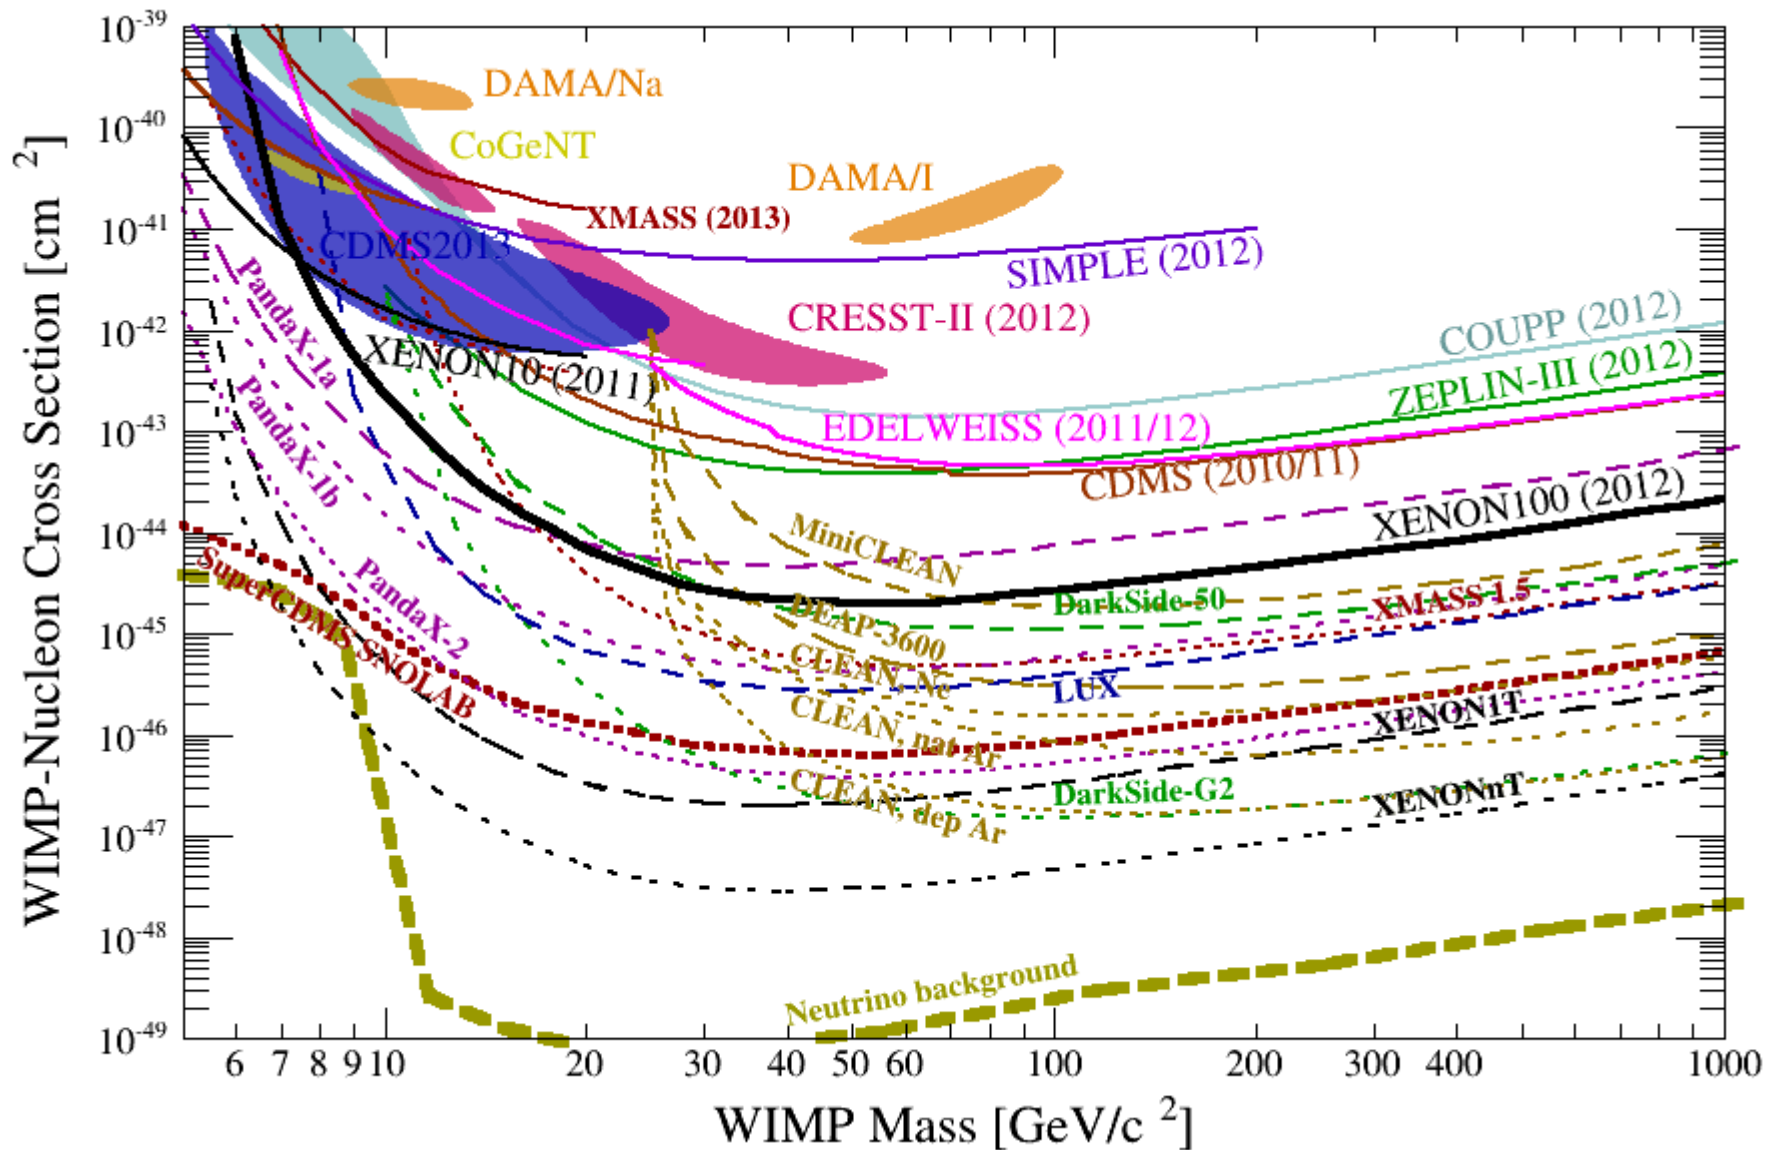

- Baseline scenario:
  - 20 t (10 t) total (fiducial) LAr/LXe mass
- Supported by ASPERA

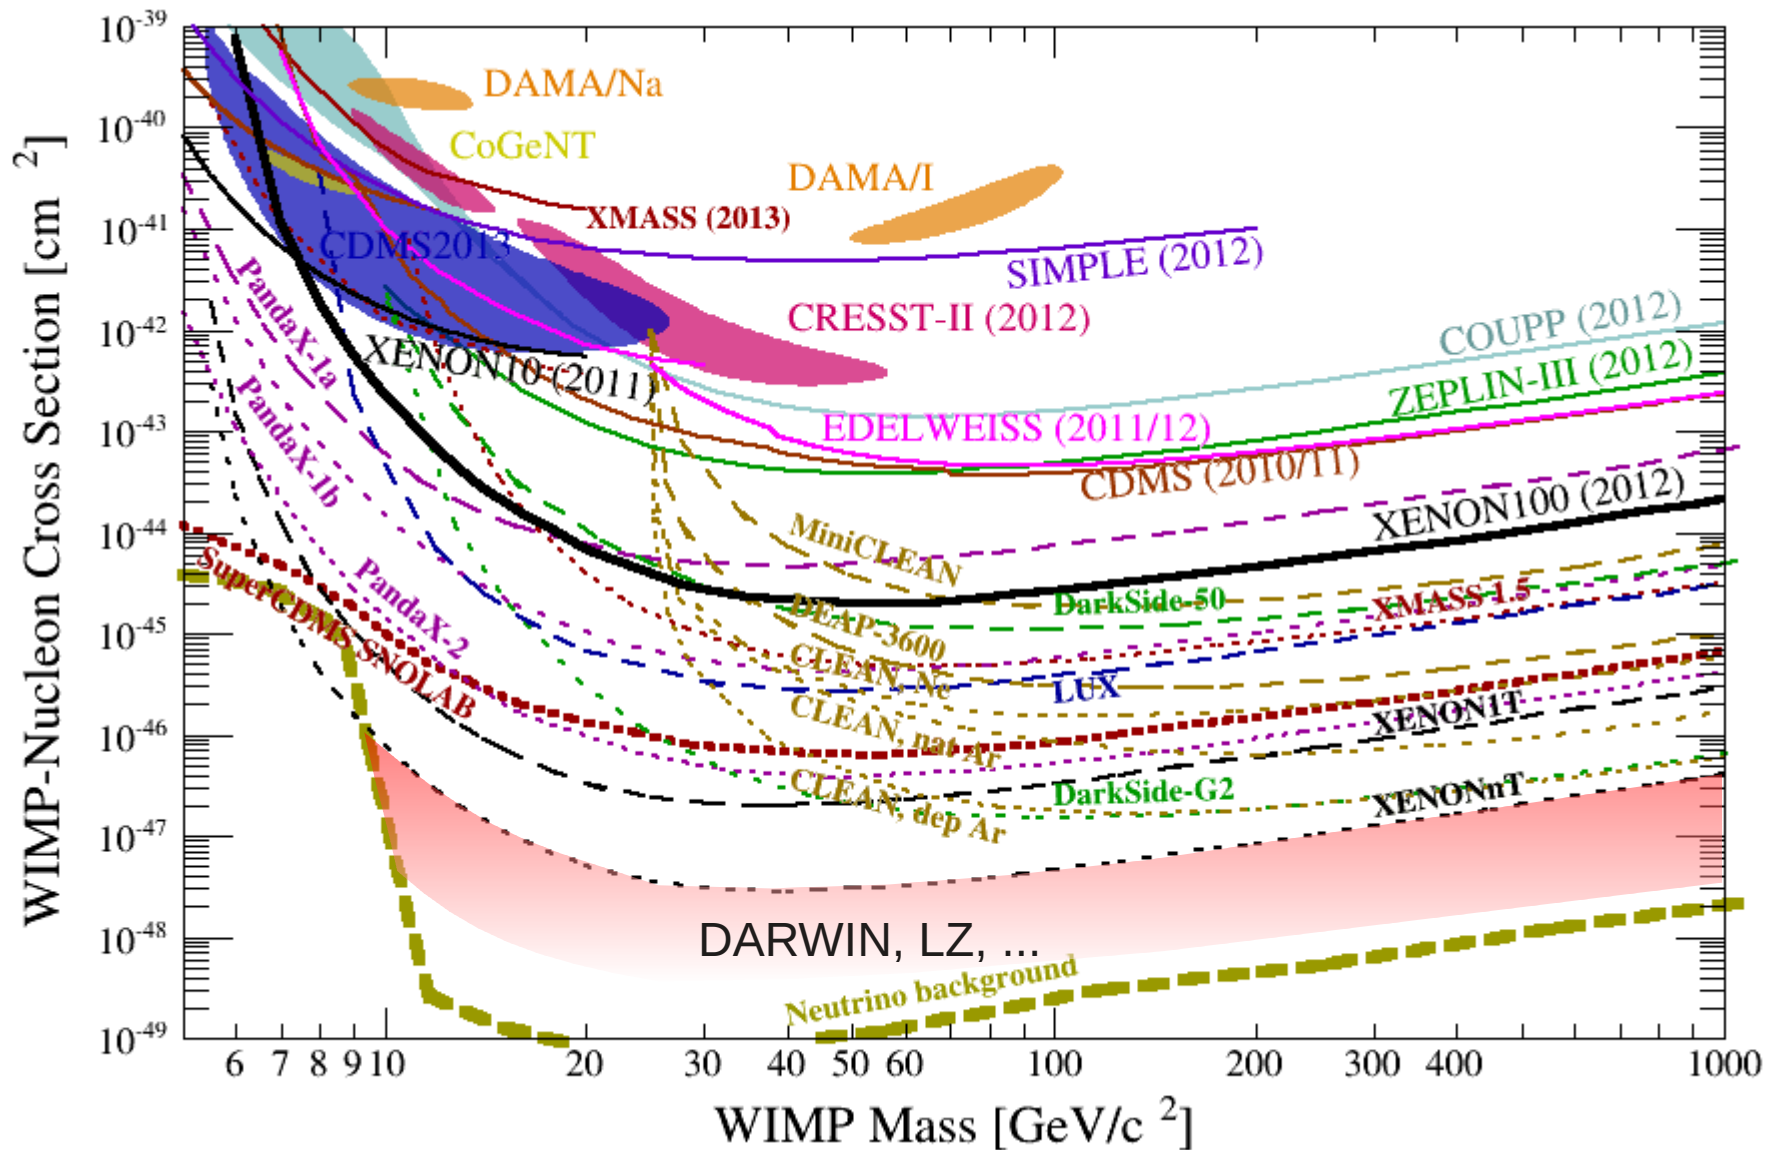

# WIMP hunting...

WIMP hunting : huge activity and competition within next decade . . .

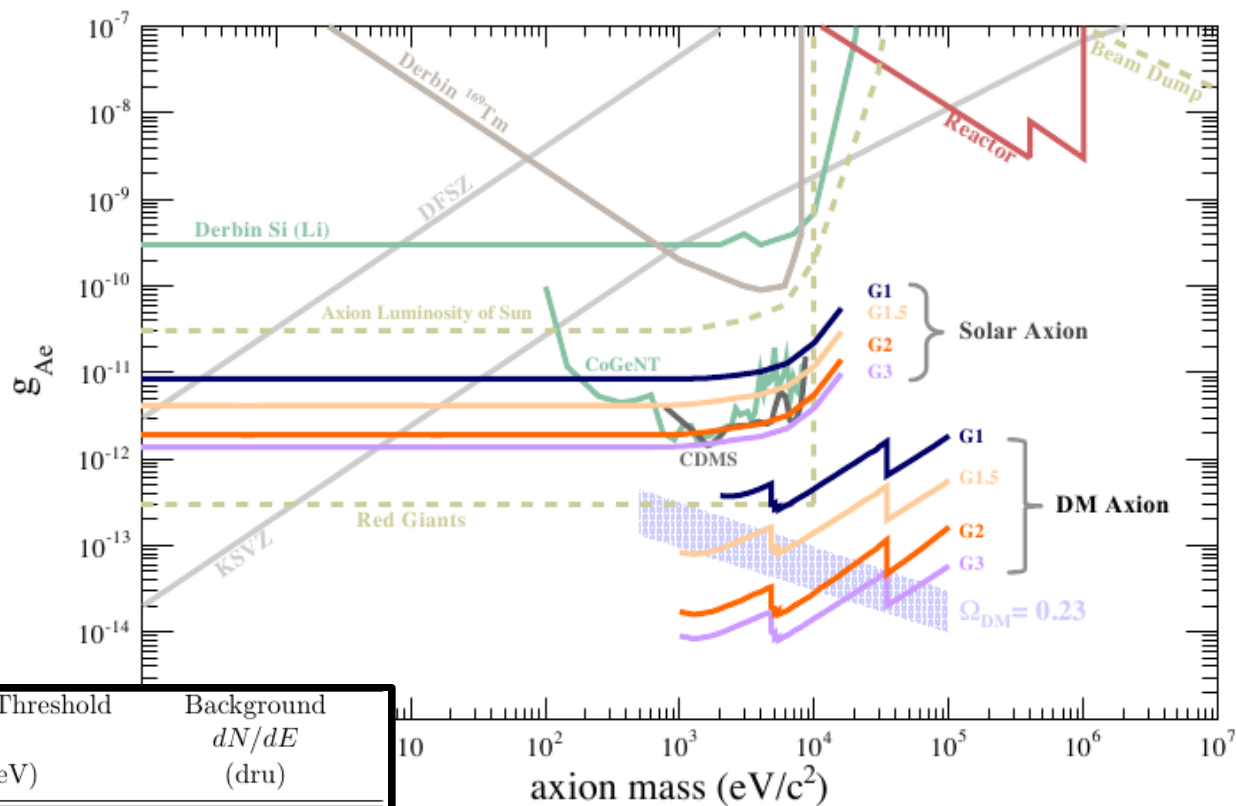

# WIMP hunting : ultimate detectors?

# Search for axions with present and future liquid xenon detectors

- Search for the existence of axions or axions-like-particles (ALPs) through their coupling to electrons  $g_{Ae}$  (axio-electric effect)
- Dual phase xenon TPCs have good potentiality for this search, as described in:  
*K. Arisaka et al. Astropart.Phys. 44 (2013) 59-67*

The potentiality of four LXe detector generations are studied, with different target masses and with an assumed level of expected background

		Weight $W$ (kg)	Live Time $T$ (years)	Resolution $b$ ( $\sqrt{\text{keV}}$ )	Energy Threshold (keV)	Background $dN/dE$ (dru)
G1	XENON100	34	$\frac{1}{2}$	0.6	2	0.01
G1.5	LUX/XMASS	100	1	0.4	1	$5 \times 10^{-4}$
G2	XENON1T	1000	2	0.4	1	$(1.4 \pm .07E) \times 10^{-5*}$
G3	XAX	10000	2	0.4	1	$1.4 \times 10^{-5\dagger}$

## Summarising

Liquid noble gas detectors currently dominate the field  
on direct dark matter searches (XENON100)

About 7 Collaborations are presently engaged in 7 long term LXe and LAr projects

Most of the projects are based on scalable detectors with increasing sensitivity.  
For all of them, the technology is mature and the background sources are taken under control

Very few “ultimate” WIMP detectors (i.e. close to the neutrino background limit) are planned
