Constraints on the  
Dark Matter, and  
Dark Energy

*Massey et al 2007*

# Tully-Fisher relation

Relation between maximum velocity  
and luminosity

$\Delta V$  corrected from inclination

Much less scatter in I or K-band  
(no extinction)

Correlation with  $V_{\text{flat}}$

Better than  $V_{\text{max}}$

Ursa cluster

*Verheijen 2001*

Tully-Fisher relation  
for gaseous galaxies  
works much better in  
adding gas mass

Relation  $M_{\text{baryons}}$   
with Rotational  $V$

$$M_b \sim V_c^4$$

McGaugh et al (2000) → **Baryonic Tully-Fisher**

# Baryonic Tully-Fisher relation

$f_b$  baryon fraction= 17%

**CDM:** Cold Dark Matter

$\Lambda$  dark energy

# Where are the baryons?

→ 6% in galaxies ; 3% in galaxy clusters as hot X-ray gas

→ <18% in the Lyman-alpha forest (cosmic filaments)

→ 5-10% in the WHIM (Warm-Hot Intergalactic Medium)  $10^5$ - $10^6$ K OVI lines

→ 65% are not yet identified or localised!

Most of them are not in galaxies

# Fraction of baryons detected

Fraction =  $M_b / (0.17 M_{500})$   $M_{500}$  dynamical mass within  $R_{500}$   
 $R_{500}$  radius where the density is 500 times the mean cosmic density

# Mass & Light Distribution Functions

$\Lambda$ CDM: Too many bright and too many faint galaxies

*Baugh 2006, Eke et al 2006, Jenkins et al 2001*

# Star Formation Feedback to fit faint end

Gas is heated in dwarfs, but falls in heavier haloes

➔ worsen the bright end problem

➔ Requires AGN feedback at the bright end

# Problems of the standard $\Lambda$ -CDM model

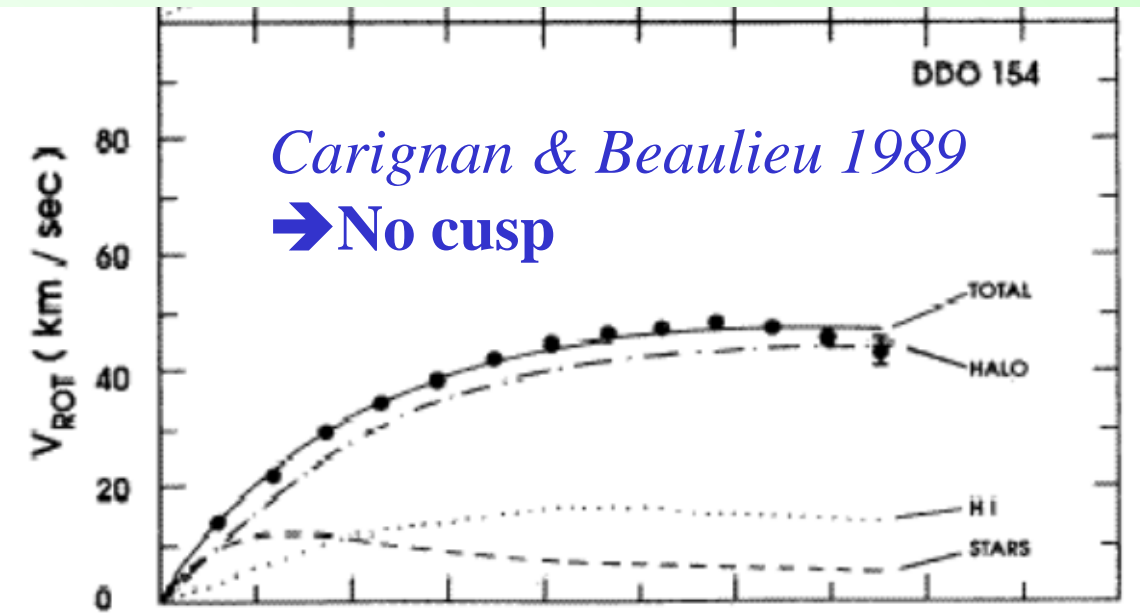

- Prediction of **cusps in galaxy center**, which are in particular absent in dw-Irr, dominated by dark matter
- Low angular momentum of baryons, and as a consequence **formation of much too small galaxy disks**
- Prediction of a **large number of small halos**, not observed

The solution to all these problems could come from some baryonic physics (SF, feedback?), or lack of spatial resolution in simulations, or wrong nature of dark matter?

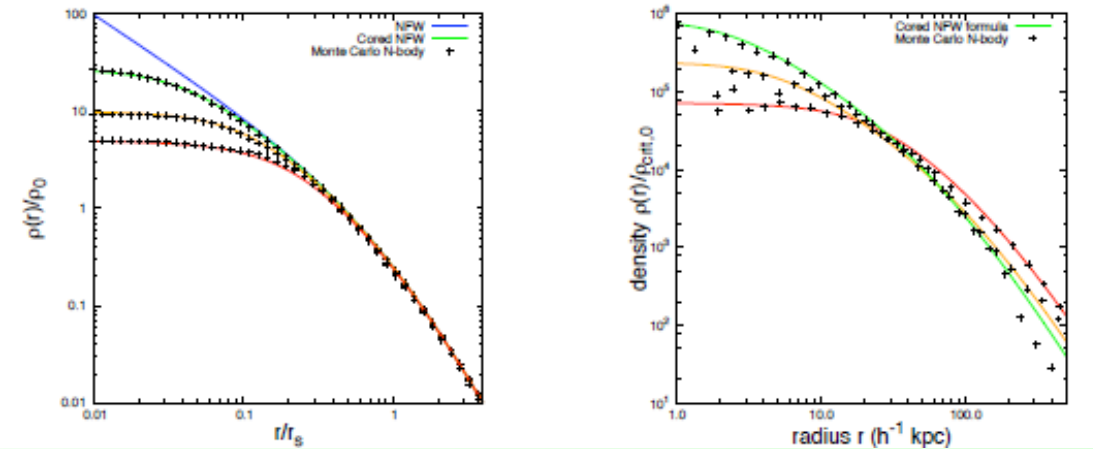

# Dwarf Irr : DDO154 the prototype

Low surface brightness galaxies are dominated by dark matter

# SIDM Self-interacting DM

Size of cusps depends on the galaxy. Dwarfs  $r_c \sim 10$  kpc  
**SIDM cross section is fit to galaxies, then too big for clusters.**

$$M_{200} = 1.7 \times 10^{14} M_{\odot}$$

Collisionless

SIDM simulations

*Koda et al 2011*

Velocity-dependent cross-sections?

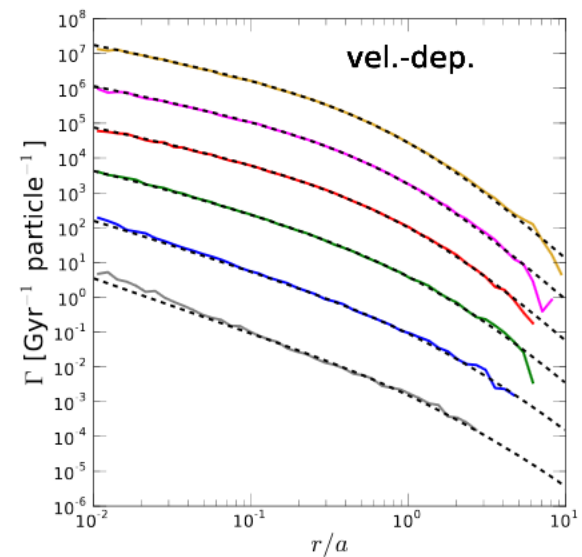

In  $v^{-\alpha}$

Or a Yukawa potential, instead  
(Loeb & Weiner 2011)

Dark force  $\rightarrow$  V-dependent scattering

# Self-interacting Dark matter vdSIDM

vdSIDM simulations, with the self-scattering  
mediated by a Yukawa field, gauge boson  $m_\phi$   
(//scattering in a Coulomb screened plasma)  
*Vogelsberger et al 2012*

# vdSIDM results

Elastic scattering: **missing satellites problem still there**

May be with energy exchange?

*Vogelsberger et al 2012*

# Problems of the WDM

To account for dwarf galaxy cores,  
 $m < \sim 0.1$  keV (Liouville theorem  $Q = \rho/\sigma^3$ )

But for large scales 3-10 keV  
is required (*Quantum mechanics effects  
intervene only at 0.1-1 pc for 2 keV*)

Dwarf galaxies have to be formed  
anyway, with a kpc scale cores.

But the  $m_{\text{WDM}}$  required for their core  
suppress the dwarf formation

*Maccio et al 2012, 13*

# Cusps and Warm DM (WDM)

The density profile is **universal**: NFW, for HDM, WDM and CDM  
(Wang & White 2009)

→ The universality is not due to mergers

In monolithic collapse, same features  
Concentrations, cusps, shapes of haloes  
Spins of haloes, kinematics

The only big difference is the power spectrum

→ Can be fitted, to limit small scales

Temperature at decoupling, could limit phase-space densities, but  $r_c/r_{200} < 10^{-3}$

Cores in galaxies  $r_c/r_{200} = 5\%$

*Villaescusa-Navarro, Dalal (2011)*

# Ly- $\alpha$ constraints on WDM

25 quasars  $z > 4$ : HIRES spectra from the Keck, *Viel et al 2013*  
+ MIKE (Magellan)

Lyman- $\alpha$  forest, compared with simulations predictions

$m_{\text{WDM}} > 3.3 \text{ keV} (2\sigma)$

1D power-spectrum, predicted  
By models

# Best fit CDM/WDM

Viel et al 2013

MIKE+  
HIRES+  
SDSS  
*Flux power spectrum*  
*Dim-less units*

Compared to  
models

# Constraints on mWDM

N(satellites)

## Two contradictory goals

1- Have a low mWDM to reduce the mass concentration (core/cusp pb)

*Low  $m$ , later formation, when the Universe density is low*

2- Have a high enough mWDM to have enough dwarfs (free-streaming)

# Structure formation in WDM

High resolution is needed  
Spurious fragmentations have been  
reported, below smoothing length

*Lovell et al 2013*

# Depends on the MW mass

If the MW mass  $< 1.2 \cdot 10^{12} M_\odot$ , WDM is ruled out

*Kennedy et al 2013*

# Missing satellites

Aquarius simulations of MW

**Predicted: Steep**

Springel et al. 2008

**Observed: flat**

Boylan-Kolchin et al. 2011

# Dwarf Spheroidals

Fornax, Leo I, Sculptor, Leo II, Sextans, Carina, Ursa Minor, Canes Venatici I, Draco

$L_v > 10^5 L_o$   
Boylan-Kolchin et al 2011

Very low surface brightness  
and dominated by dark matter

These dSph are not obtained  
In CDM simulations

# Abundance matching for satellites

## Stellar mass matching

Springel et al. 2008

Boylan-Kolchin et al. 2011

# Misfits of satellites

*Boylan-Kolchin et al 2012*

From halo abundance matching,  
the efficiency to form stars is derived,  
→ must peak at 20% of baryons in stars  
at  $M_{\text{tot}} \sim 10^{12} M_{\odot}$  (MW-type galaxies)

9-10 satellites  
with  $L_v > 10^5 L_{\odot}$

$$\frac{M_{*}}{f_b M_{\text{DM}}}$$

# Too Big To Fail (TBTf) problem

## Dwarf Spheroidals of the Local Group, $M_* \sim 10^6$ Mo, $V_{\text{cir}}$ vs $R$

Numerical simulations predict dense cusps, which cannot correspond to any of the dSph observed (*Boylan-Kolchin et al 2012*)

Repeated blow-out due to supernovae  
have been simulated, to destroy the haloes

A single burst of the same total mass is better

But 40 000 SN are required with 100% efficiency

→ SF feedback cannot solve the problem

*Garrison-Kimmel et al 2013*

## Modification at weak acceleration

$$a = (a_0 a_N)^{1/2}$$

$$a_N \sim 1/r^2 \rightarrow a \sim 1/r \rightarrow V^2 = \text{cste}$$

$$\nabla \cdot [\mu(|\nabla\phi|/a_0)\nabla\phi] = 4\pi G\rho$$

$$\rightarrow a^2 \sim V^4/R^2 \sim GM/R^2 \text{ (TF)} \quad (\text{Milgrom 1983})$$

$$a_N = a \mu(x)$$

$$x = a/a_0 \quad a_0 = 1.2 \cdot 10^{-10} \text{ m/s}^2 \quad \text{or} \quad 1 \text{ Angstroms/s}^2$$

$$x \ll 1 \text{ Mondian regime} \quad \mu(x) \rightarrow x$$

$$x \gg 1 \text{ Newtonian} \quad \mu(x) \rightarrow 1$$

Covariant theory: TeVeS

Account for lensing

# Dynamic Mass / Visible Mass

The ratio remarkably depends on acceleration,

→ The only variable controlling the gravity regime universally

Radius

Velocity

Acceleration

# Tully-Fisher relation

$$g_M^2 = a_0 g_N = a_0 GM/r^2 = V^4/r^2$$

$$\rightarrow V^4 = a_0 GM$$

Rotation curves are fit for all types  
(dwarfs **LSB**, giant **HSB**)

**LSB N1560**

**HSB N2903**

# Pressure-supported systems

Sanders & McGaugh 2002

From GC to galaxies  
and clusters

$$\sigma_l^2 / r = a_0$$

# Multiple rotation curves..

All types, all masses, with the same parameter  $a_0$ ,  
universal for  $\sim 1000$  curves *Sanders & Verheijen 1998*

# Problems of MOND in galaxy clusters

Inside galaxy clusters, there still exists some missing mass, which cannot be explained by MOND, since **the cluster center** is only moderately in the MOND regime ( $\sim 0.5 a_0$ )

Observations in X-rays: hot gas in hydrostatic equilibrium, and weak gravitational lenses (shear)

MOND reduces by a factor 2 the missing mass

➔ It remains another component, which could be neutrinos....  
(plus baryons)

The baryon fraction is not the universal one in clusters  
(so baryons could still exist in the standard  $\Lambda$ CDM model)

But if CDM does not exist, there is no limiting fraction

# MOND & galaxy clusters

According to baryon physics, cold gas could accumulate at the cluster centers

Alternatively, neutrinos could represent 2x more mass than the baryons

# The bullet cluster

X-ray gas

Proof of the existence of non-baryonic matter

Total mass

Accounted for in MOND + neutrinos (2eV, Angus et al 2006) <sup>37</sup>

# CDM simulation

Collision velocity from the bow-shock =  $4700 \pm 500 \text{ km/s}$  (Mach 3)

Hayashi & White 2006 Farrar & Rosen 2007

→ impossible to reconcile with CDM

Milosavljevic et al 2007, Springel & Farrar 2007

CDM can only

$V < 3500 \text{ km/s}$

MOND  $> 4500 \text{ km/s}$

Relative velocities  
between halos

4 times higher in MOND

Linares et al 2009

Collision by 16%  
over-estimated?

$V_{\text{gas}}$  could be higher  
than  $V_{\text{CDM}}$

Mahdavi et al 2007

# Abell 520

$z=0.201$

Red= X-ray gas  
Contours= lensing  
→ Massive DM core  
Coinciding with X gas  
but devoid of galaxies

Cosmic train wreck

Opposite case!

# Abell 520 merging clusters

Contours=total mass

Contours = X-ray gas

How are the galaxies ejected from the CDM peak??

# A520: Dark core with X-ray

Jee et al 2012

Dark core at  $10\sigma$   
Contours of DM  
(weak lensing HST)  
on X-ray (red)

B-band CFH (blue)

Collisional dark matter?  $\sigma_{\text{DM}}/m_{\text{DM}} \sim 3.8 \text{ cm}^2/\text{g}$   
Real counter-example of the bullet  
where  $\sigma_{\text{DM}}/m_{\text{DM}} < 1 \text{ cm}^2/\text{g}$

# **Constraints from galaxy dynamics and observations**

**Are the stability, evolution & formation of  
galaxies stringent tests of the theory?**

- Galaxy interactions**
- Bars and their pattern speeds**
- Different dynamical friction**

# Influence of DM halo

With DM halo

Without DM (MOND)

# Bar strength and pattern speed with and w/o DM

With DM, the bar appears later, and can reform after the peanut weakening through halo AM exchange,  $\rightarrow$  But  $\Omega_b$  falls off

# Interactions of galaxies: the Antennae: MOND versus CDM

Dynamical friction is much lower with MOND: mergers last much longer

Also much longer time-scale for merging of dissipationless galaxies (Nipoti et al 2007)

# Simulations of the Antennae

# Dynamical friction

Analytically, the dynamical friction is **predicted stronger** with MOND than in the equivalent Newtonian system with dark matter

*Ciotti & Binney 2004 (CB04), Nipoti et al 2008*

However simulations show DF **less efficient** in galaxy interactions

In CDM, a lot of particles acquire E and AM, and **DF concept applicable**

➔ In MOND, a small number of particles in the outer parts acquire big quantities (no analytical treatment)

*Nipoti et al 2007, Tiret & Combes 2007*

# Merger induced starbursts degeneracy

**CDM:** dynamical friction on DM particles very efficient  
→ mergers in one passage

**MOND:** with the same angular momentum, merger will require many passages

Starburst at each passage when minimal approach

→ Number of "merger/SB" can be explained both ways

# Formation of Tidal Dwarf Galaxies

Exchange of AM is within the disk: ➔ much easier with MOND to form TDG

In DM, requires very extended DM distribution (Bournaud et al 03)

# TDG in N5291 HI ring

# Dynamics of the TDGs

With MOND, *Gentile et al 2007*

All inclinations =  $45^\circ$ , from simulations (Bournaud et al 07)  $\rightarrow$  dark  $H_2$

# MOND and the dark baryons

Is MOND compatible with the existence of dark gas in galaxies? What fraction provides the best fit to the rotation curves?

Fit of  $\sim 50$  rotation curves,  $c = M(\text{dark})/M_{\text{HI}}$

# Combination with MOND

NGC 1560: fits with variation of  $a_0 \sim 1/(\text{gas}/\text{HI})$

$$V^4 = a_0 \text{ GM}$$

*Tiret & Combes 2008*

# Dark matter in Ellipticals

Planetary Nebulae: Romanowsky et al 2003

Dearth of dark matter??

..... Visible matter (isotropic)

- - - isothermal (isotropic)

# Anisotropy of velocities

$$\beta = 1 - \sigma_{\theta}^2 / \sigma_r^2, \quad -\infty, 0, 1$$

$\beta$  circular, isotropic and radial orbits

When galaxy form by mergers,  
orbits in the outer parts are  
strongly radial, which could explain  
the low projected dispersion  
(Dekel et al 2005)

The observation of the velocity profile is somewhat degenerate  
and cannot lead to the dark matter content univocally

Young stars are  
in yellow contours

Comparison with data for  
N821 (green), N3379(violet)  
N4494 (brown), N4697 (blue)

# DM profile from satellites

SDSS, 2500 deg<sup>2</sup>, 3000 satellites  $M_b = -16, -18$  (galaxies  $-14$ )

Removal of interlopers

$\sigma_v = 120 \text{ km/s}$  at 20kpc and 60km/s at 350kpc (Prada et al 2003)

→ Declines agree with  $\rho \sim r^{-3}$  of NFW (CDM profile)

$\sigma_v$  within 100kpc varies as  $L^{0.3}$ , quite close to TF relation

In average 2 satellites per galaxy, and 0.2 interlopers

See also McKay et al (2002)  $\sigma \sim L^{0.5}$  from 1225 SDSS satellites  
 $M_{260}$  in agreement with lensing results

**But flat velocity dispersion recovered (as if  $\rho \sim r^{-2}$ )**

# Satellites in SDSS

Klypin &  
Prada 2009

Statistical  
satellites

Only 1 or 0  
for each galaxy

# Test of the SDSS satellites

2 types of CDM **CDM1: NFW cusp**

CDM2: as required by rotation curves

*Tiret et al 2007*

# Tully Fisher Equivalent

Asterisk: Lenses  
(Hoekstra et al 2002)

--- TF normal  
spirals  
(Verheijen 2001)

Prada et al (2003)

# Polar rings from cosmic gas accretion

Also Snaith et al 2012

→ After 1.5 Gyr, interaction between the two disks destroys the PRG

→ Velocity curve about the same in both equatorial and polar planes

Brook et al 2008

# The TF of Polar Ring Galaxies

Iodice et al 2003  
Combes et al 2013

# Polar Ring Galaxies with MOND

Map of the phantom  
dark matter

*Lüghausen et al 2013*

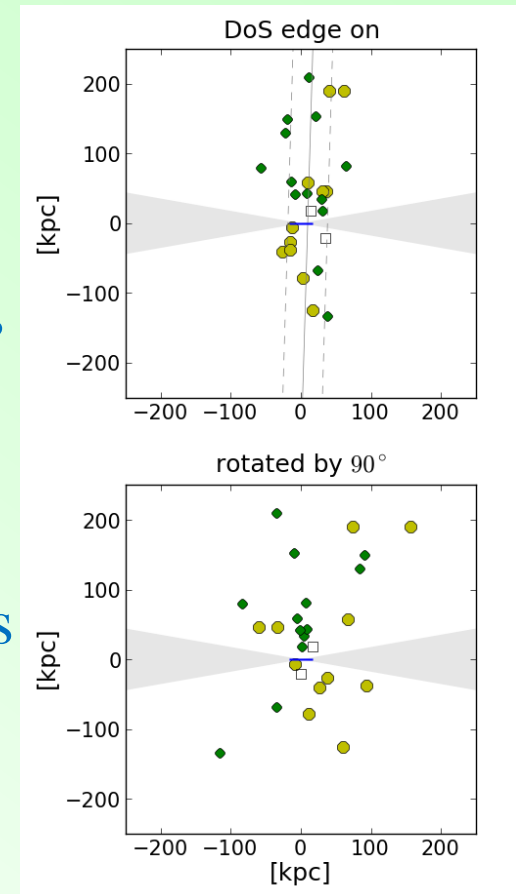

# Disks of Satellites, MW, M31

Ibata et al 2013, Nature

Pawlowski et al 2012

Rotationally  
supported  
plane of satellites

Never found in  
CDM simulations

Metz et al 2008 64

# Are all these satellites Tidal dwarfs (TDG)?

When 2 spiral galaxies merge, the tidal tails follow the initial plane orientations

→ Explain the alignment

However, the TDG formed have no dark matter

In the MW, M31, these dwarfs are dominated by dark matter

# MOND cosmological simulations

Starting  $z=50$ , dissipationless matter, 2 low  $\Omega$  models +  $\Lambda$ CDM

Easier to form large masses early

Llinares et al 2009

$z=2$

$z=5$

# Evolution with time

Does the critical acceleration vary?

$$a_0 \sim c H_0, \text{ or also } a_0 \sim c (\Lambda/3)^{1/2}$$

Possible to imagine variations, in either way (more or less MOND in the early universe)

Open question, as is the evolution of  $\Omega_\Lambda$

# Fit of CMB data, Planck coll

**Challenge for MOND: must include massive neutrinos 1-2eV**

$$\Omega_\Lambda=78\% \quad \Omega_\nu=17\% \quad \Omega_b=5\%$$

# TeVSe: CMB and LSS

Skordis 2009

Growth of structures due to the vector field  
Scalar field  $\rightarrow$  acceleration of expansion, DE

# WMAP-5 + ACBAR

The 3rd peak is not lower (damped) than the 2<sup>nd</sup> peak  
There must exist something else: sterile neutrinos,  
or other terms in relativistic theory (BSTV)

Angus (2011)

# Conclusion: Success and Problems of each model

**CDM:** great success at large scale, but problems at galaxy scales

**WDM:** does not solve the cusps, not enough small-scale power

**MOND** solves the problems of galaxies,

but has to solve its own problem at group and cluster scales  
(neutrinos, baryons..)

→ More tuned SN and AGN feedback, to solve CDM models

Numerical simulations with improved physics, resolution

→ Lorentz covariant theory, TeVeS (Bekenstein 2004) with  
a lot of varieties (GEA, BSTV, k-essence..)

→ Different metric (BIMOND), still free parameters to explore

Other propositions? Modif of inertia?, non-local? Dipolar DM..

Acceleration parameter  $a \sim V_f^4/M_b$

Famaey & McGaugh 2012
