Triumph of the Standard Model

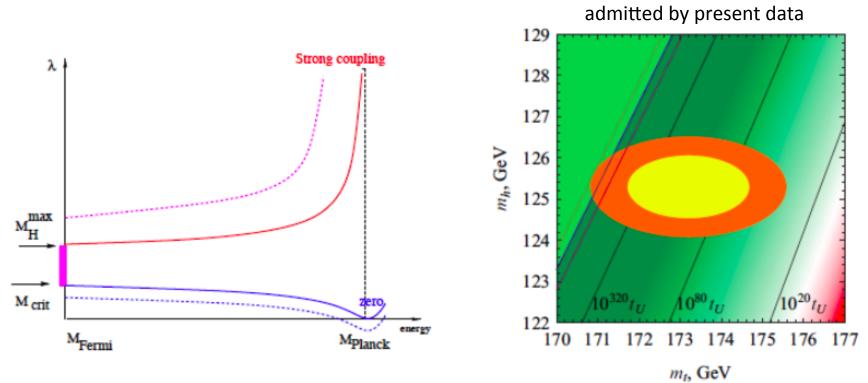

Theoretical motivation

- Discovery of the 126 GeV Higgs boson → Triumph of the Standard Model The SM may work successfully up to Planck scale !
- SM is unable to explain:
 - Neutrino masses
 - Excess of matter over antimatter in the Universe
 - The nature of non-baryonic Dark Matter
- All three issues can be solved by adding three new fundamental fermions, right-handed Majorana Heavy Neutral Leptons (HNL): N₁, N₂ and N₃

SM may well be a consistent effective theory all the way up to the Plank scale

- ✓ M_H < 175 GeV → SM is a weakly coupled theory up to the Plank energies !
- ✓ M_H > 111 GeV → EW vacuum is stable or metastable with a lifetime greatly exceeding the age of our Universe (Espinosa et al)

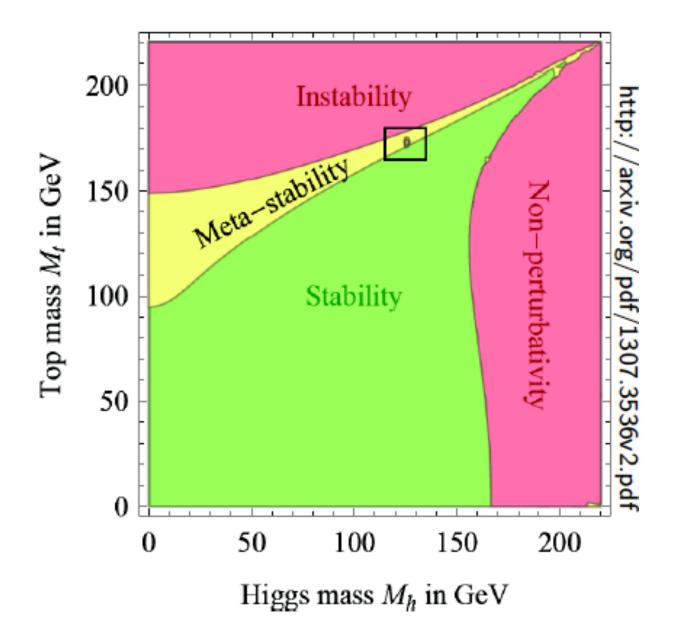

✓ No sign of New Physics seen

4

Stable vacuum is perfectly

Hard to believe that this is a pure coincidence !

No sign of New Physics seen What is not found..

Summary of CMS RPV SUSY Results*

EPSHEP 2013

Bounds on the scale of New Physics

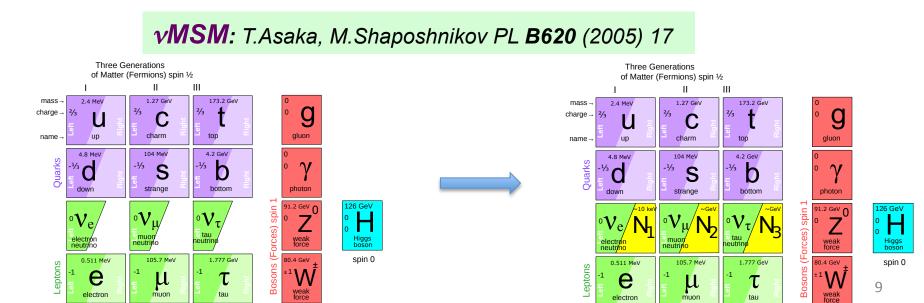

Most stringent limits come from observables in BB mixing

8

Theoretical motivation

- Discovery of the 126 GeV Higgs boson → Triumph of the Standard Model The SM may work successfully up to Planck scale !
- SM is unable to explain:
 - Neutrino masses & oscillations
 - Excess of matter over antimatter in the Universe
 - The nature of non-baryonic Dark Matter
- All three issues can be solved by adding three new fundamental fermions, right-handed Majorana Heavy Neutral Leptons (HNL): N₁, N₂ and N₃

See-saw generation of neutrino masses

Most general renormalisable Lagrangian of all SM particles (+3 singlets wrt the SM gauge group):

$$L_{\text{singlet}} = i\bar{N}_I\partial_\mu\gamma^\mu N_I - Y_{I\alpha}\bar{N}_I^c\tilde{H}L^c_\alpha - M_I\bar{N}_I^cN_I + \text{h.c.}$$

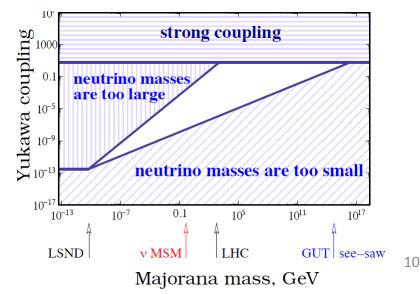

Yukawa term: mixing of N_I with active neutrinos to explain oscillations

Majorana term which carries no gauge charge

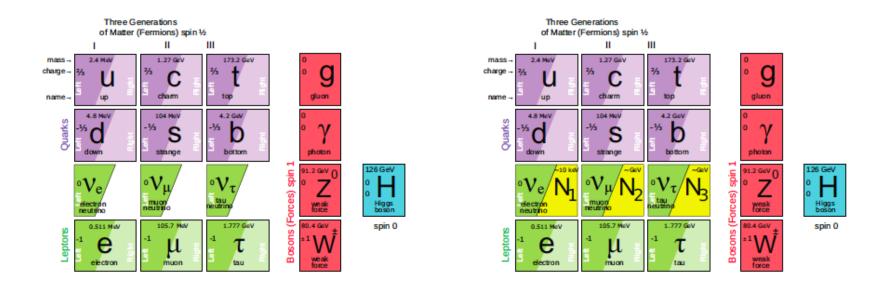

The scale of the active neutrino mass is given by the see-saw formula: $m_{\nu} \sim where m_D \sim Y_{I\alpha}v$ - typical value of the Dirac mass term

Example:

For $M \sim 1$ GeV and $m_v \sim 0.05$ eV it results in $m_D \sim 10$ keV and Yukawa coupling $\sim 10^{-7}$

The vMSM model

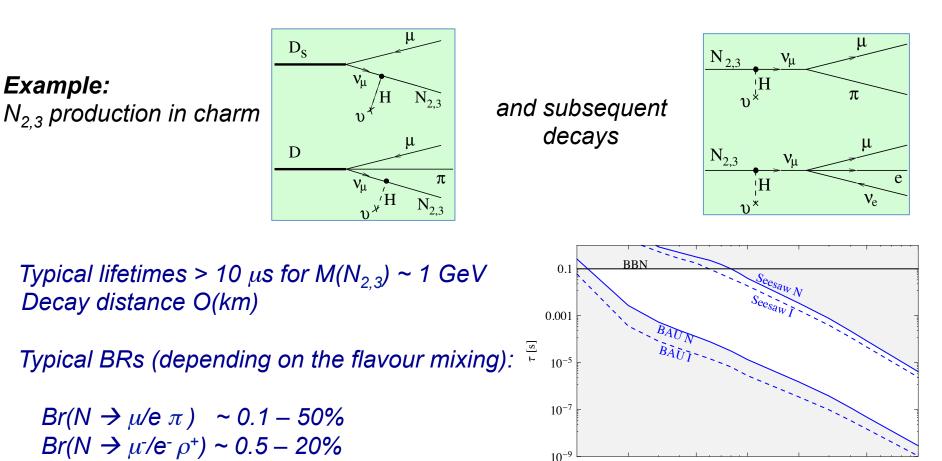

N = Heavy Neutral Lepton - HNL

Role of N_1 with mass in keV region: dark matter Role of N_2 , N_3 with mass in 100 MeV – GeV region: "give" masses to neutrinos and produce baryon asymmetry of the Universe Role of the Higgs: give masses to quarks, leptons, Z and W and inflate the Universe.

Masses and couplings of HNLs

- N_1 can be sufficiently stable to be a DM candidate, $M(N_1) \sim 10 \text{ keV}$
- M(N₂) ≈ M(N₃) ~ a few GeV → CPV can be increased dramatically to explain Baryon Asymmetry of the Universe (BAU)

Very weak $N_{2,3}$ -to-v mixing (~ U^2) $\rightarrow N_{2,3}$ are much longer-lived than the SM particles

10.0

 $Br(N \rightarrow v\mu e) \sim 1 - 10\%$

•

Dark Matter candidate HNL N₁

Yukawa couplings are small \rightarrow *N* can be very stable.

Main decay mode: $N \rightarrow 3\nu$. Subdominant radiative decay channel: $N \rightarrow \nu\gamma$. For one flavour:

$$au_{N_1} = 10^{14}\, ext{years} \left(rac{10\ ext{keV}}{M_N}
ight)^5 \left(rac{10^{-8}}{ heta_1^2}
ight)$$

$$heta_1 = rac{m_D}{M_N}$$

Dark Matter candidate HNL N₁

DM particle is not stable. Main decay mode $N_1 \rightarrow 3\nu$ is not observable. Subdominant radiative decay channel: $N \rightarrow \nu\gamma$. Photon energy: $E_{\gamma} = \frac{M}{2}$

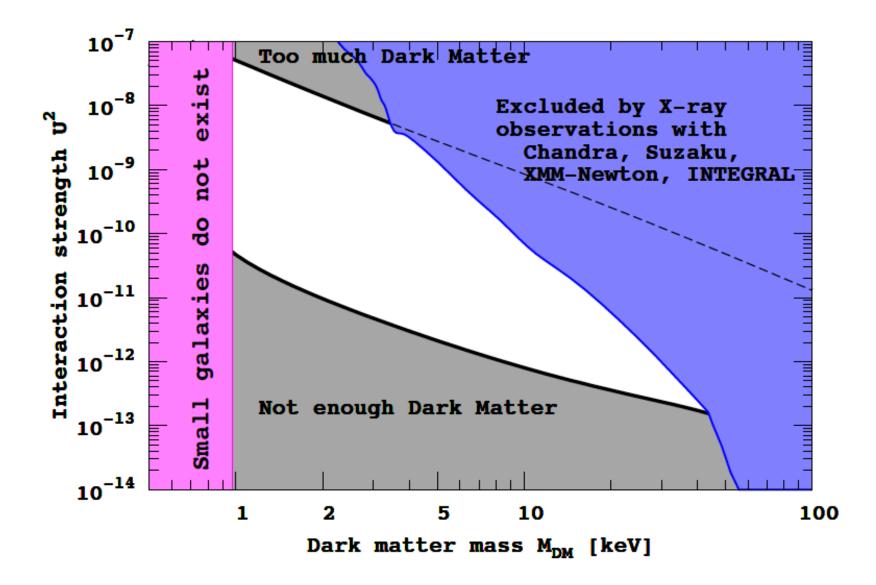

Radiative decay width:

$$\Gamma_{
m rad} = rac{9\,lpha_{ extsf{EM}}\,G_F^2}{256\cdot 4\pi^4}\,\sin^2(2 heta)\,{M_{ extsf{N}}}^5$$

Constraints on DM HNL N₁

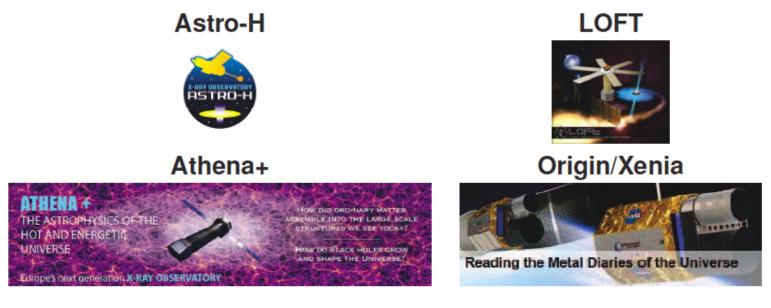

- ✓ **Stability** → N_1 must have a lifetime larger than that of the Universe
- ✓ **Production** → N_1 are created in the early Universe in reactions $l\bar{l} \rightarrow vN_1$, $q\bar{q} \rightarrow vN_1$ etc. Need to provide correct DM abundance
- ✓ Structure formation → N_1 should be heavy enough ! Otherwise its free streaming length would erase structure non-uniformities at small scales (Lyman- α forest spectra of distant quasars and structure of dwarf galaxies)
- ✓ X-ray spectra → Radiative decays N₁→_γv produce a mono-line in photon galaxies spectrum. This line has not yet been seen by X-ray telescopes (such as Chandra or XMM-Newton)

Allowed parameter space for DM HNL N₁

Searches for DM HNL N₁ in space

- Has been previously searched with XMM-Newton, Chandra, Suzaku, INTEGRAL
- Spectral resolution is not enough (required $\Delta E/E \sim 10^{-3}$)
- Proposed/planned X-ray missions with sufficient spectral resolution:

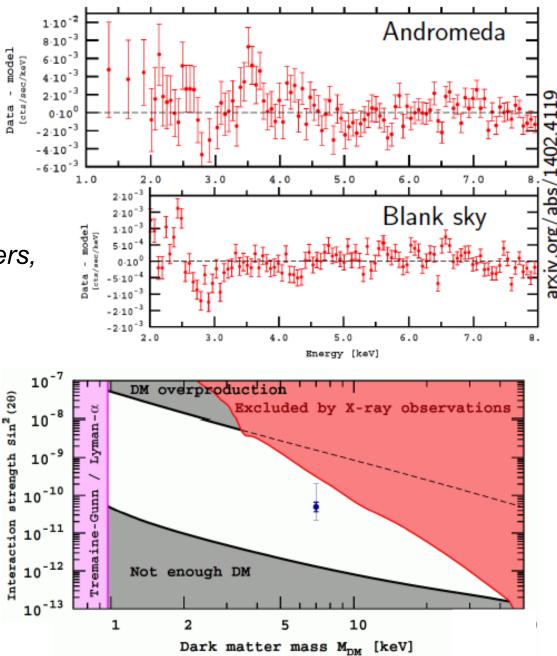

New line in photon galaxy spectrum ???

Two recent publications in arXiv:

- arXiv 1402.2301 Detection of an unidentified emission line in the stacked X-ray spectrum of Galaxy Clusters, $E_{\gamma} \sim 3.56 \text{ keV}$
- arXiv 1402.4119 An unidentified line in X-ray spectra of the Andromeda galaxy and Perseus galaxy cluster, $E_{\gamma} \sim 3.5 \text{ keV}$

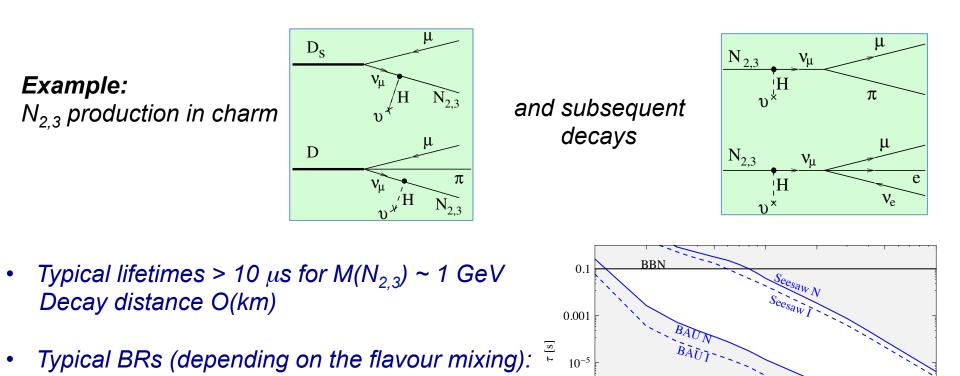

Will soon be checked by Astro-H with better energy resolution

Masses and couplings of HNLs

 M(N₂) ≈ M(N₃) ~ a few GeV → CPV can be increased dramatically to explain Baryon Asymmetry of the Universe (BAU)

Very weak $N_{2,3}$ -to-v mixing (~ U^2) $\rightarrow N_{2,3}$ are much longer-lived than the SM particles

 10^{-7}

 10^{-9}

0.2

0.5

2.0

5.09

10.0

Br(N → μ/e π) ~ 0.1 - 50% Br(N → μ⁻/e⁻ ρ⁺) ~ 0.5 - 20% Br(N → νμe) ~ 1 - 10%

Baryon asymmetry

Sakharov conditions:

• CP is not conserved in vMSM

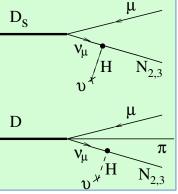

6 CPV phases in the lepton sector and 1 CKM phase in the quark sector (to be compared with only one CKM phase in the SM)

- Deviations from thermal equilibrium
- ✓ HNL are created in the early Universe
- ✓ CPV in the interference of HNL mixing and decay
- ✓ Lepton number goes from HNL to active neutrinos
- Then lepton number transfers to baryons in the equilibrium sphaleron processes
 - **PS** Explanation of DM with N_1 reduces a number of free parameters \rightarrow Degeneracy of $N_{2,3}$ masses is required to ensure sufficient CPV

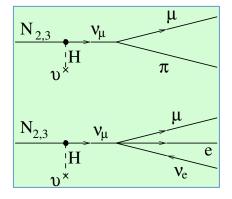

Masses and couplings of HNLs

Very weak $N_{2,3}$ -to-v mixing (~ U^2) $\rightarrow N_{2,3}$ are much longer-lived than the SM particles

Example: N_{2,3} production in charm

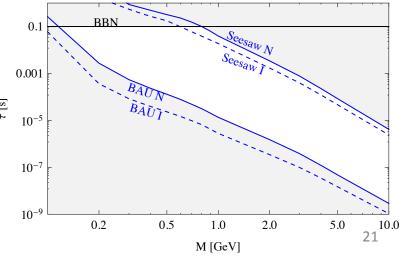

and subsequent decays

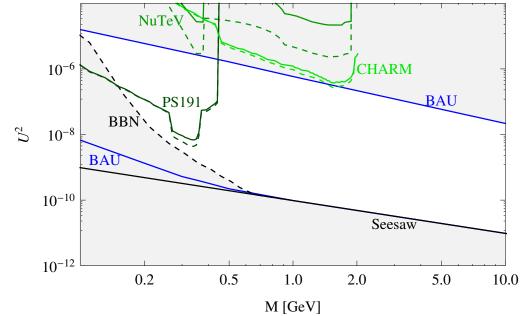

- Typical lifetimes > 10 μ s for $M(N_{2,3}) \sim 1 \text{ GeV}$ Decay distance O(km)
- Typical BRs (depending on the flavour mixing): [™]

Br(N → μ/e π) ~ 0.1 - 50% Br(N → μ⁻/e⁻ ρ⁺) ~ 0.5 - 20% Br(N → νμe) ~ 1 - 10%

Experimental and cosmological constraints

- Recent progress in cosmology

 The sensitivity of previous experiments did not probe the interesting region for HNL masses above the kaon mass

Strong motivation to explore cosmologically allowed parameter space

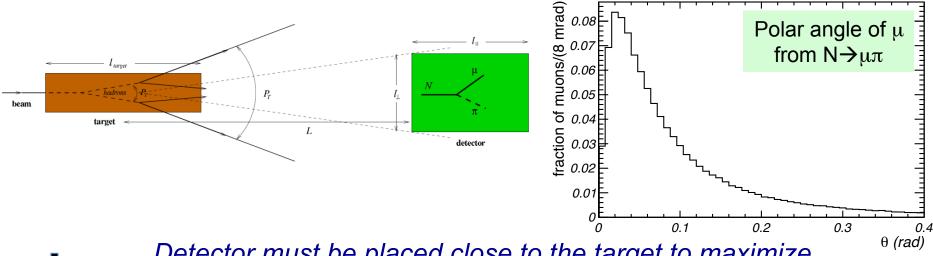

Proposal for a new experiment at the SPS, SHIP to search for new long-lived particles produced in charm decays (more details can be found at <u>http://ship.web.cern.ch/ship</u>) Experimentally this domain has not been very well explored ! 22

Experimental requirements

• Search for HNL in Heavy Flavour decays

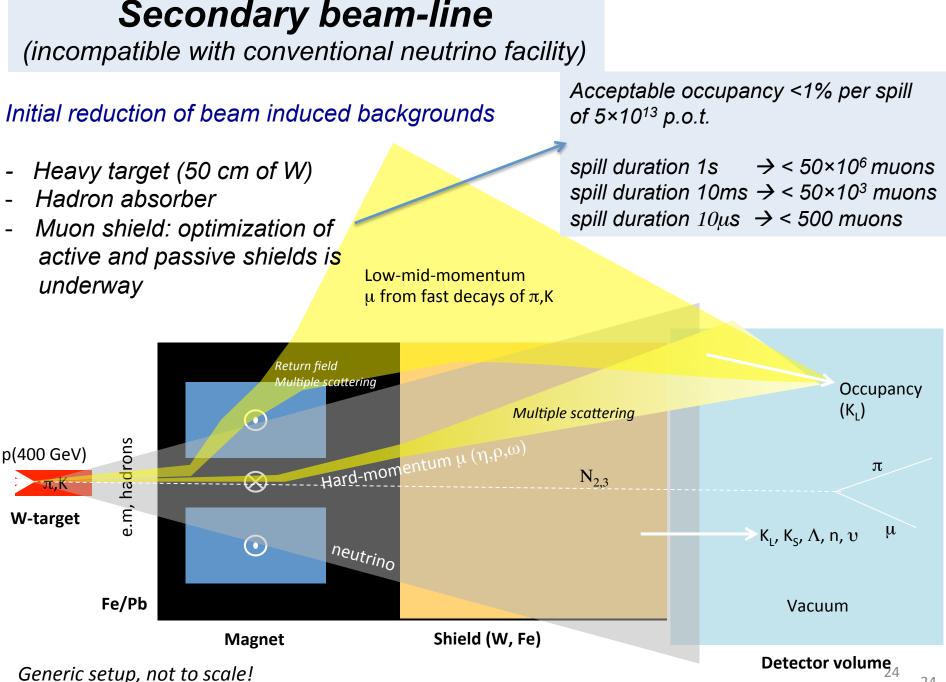

Beam dump experiment at the SPS with a total of 2×10²⁰ protons on target (pot) to produce large number of charm mesons

• HNLs produced in charm decays have significant P_{T}

Detector must be placed close to the target to maximize geometrical acceptance

Effective (and "short") muon shield is essential to reduce
 muon-induced backgrounds (mainly from short-lived resonances accompanying charm production)

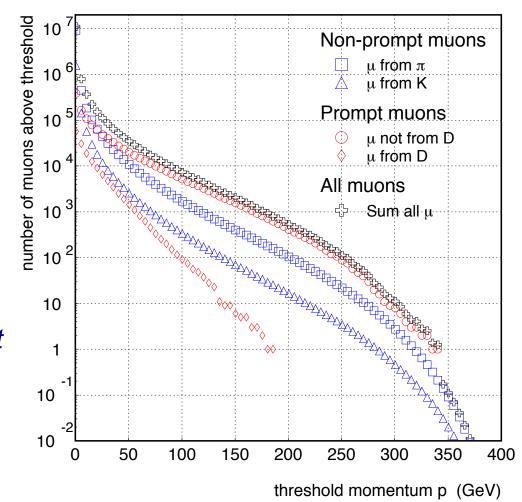

Secondary beam-line (cont.)

Muon shield

Main sources of the muon flux (estimated using PYTHIA with 10⁹ protons of 400 GeV energy)

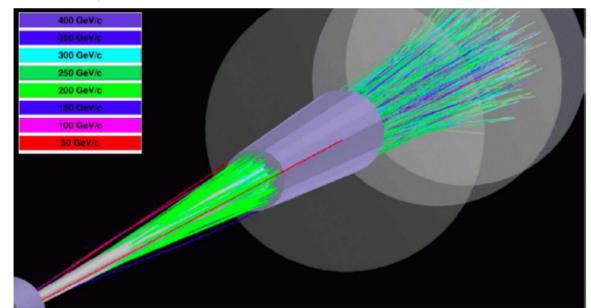

- A muon shield made of ~55 m W(U) should stop muons with energies up to 400 GeV
- Cross-checked with results from CHARM beam-dump experiment
- Detailed simulations will define the exact length and radial extent of the shield

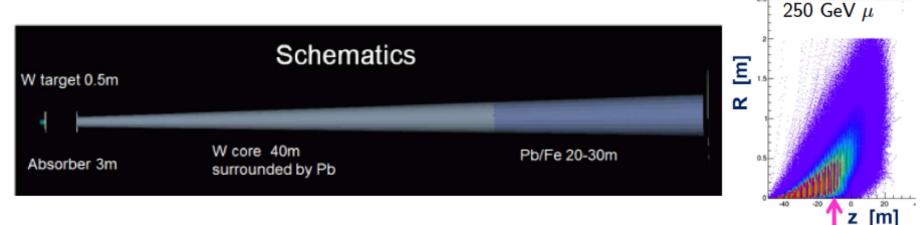

Muon shield optimization

Passive μ -filter

- Geant studies to estimate flux.
- MS and €: limit W-length to 40 m.
- High-p at small θ : WØ12-50 cm
- +20-30 m of Pb/Fe :
- reduction of 10^7 possible
- Robust/easy to operate

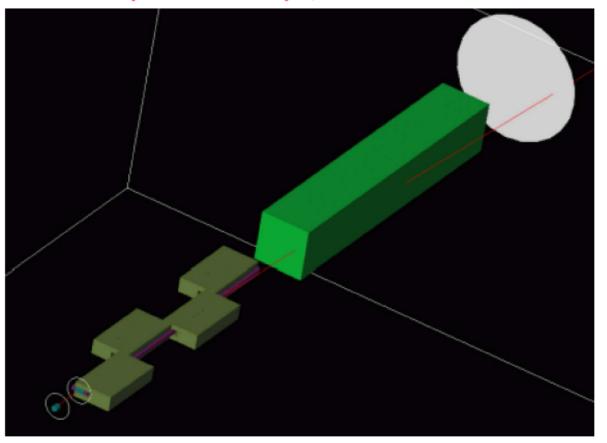

Muon shield optimization

Alternative: Active (+passive) μ -filter

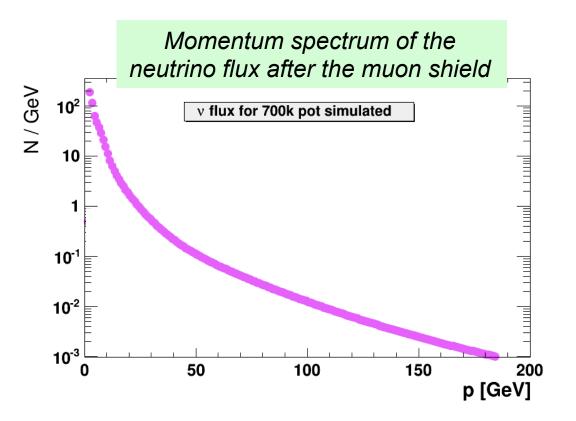

- Use 6 m long C-shaped magnets.
- Produces 40 Tm total field with 4 magnets: high-p swept out.
- Problem: return-B of low-p μ :
- alternate return-B left/right
- Add passive Fe-shield
- reduction of $10^7\ {\rm possible}$

Work in progress, need to optimize together with SPS-spill length, and induced background.

Experimental requirements (cont.)

- Minimize background from interactions of active neutrinos in the detector decay volume
 - Requires evacuation of the detector volume

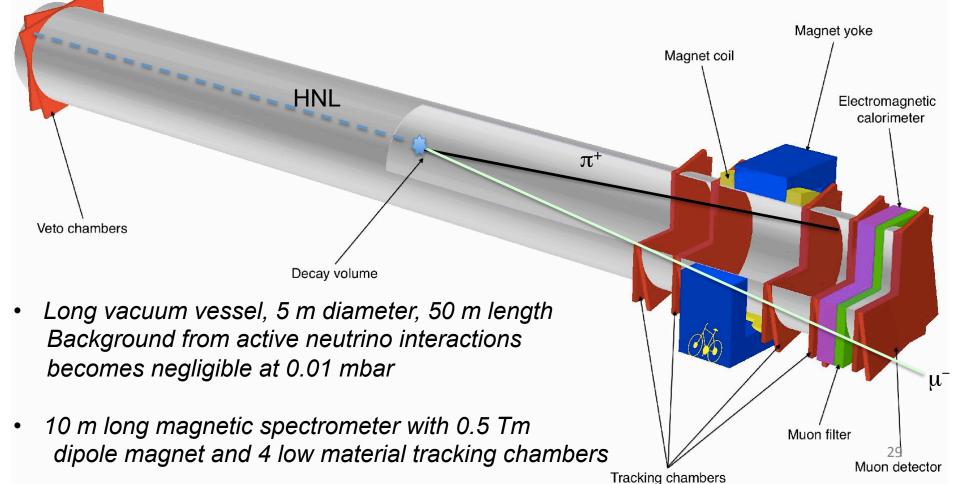

2×10⁴ neutrino interactions per 2×10²⁰ pot in the decay volume at atmospheric pressure \rightarrow becomes negligible at 0.01 mbar

Detector concept (based on existing technologies)

• Reconstruction of the HNL decays in the final states: $\mu^-\pi^+$, $\mu^-\rho^+$ & $e^-\pi^+$

Requires long decay volume, magnetic spectrometer, muon detector and electromagnetic calorimeter, preferably in surface building

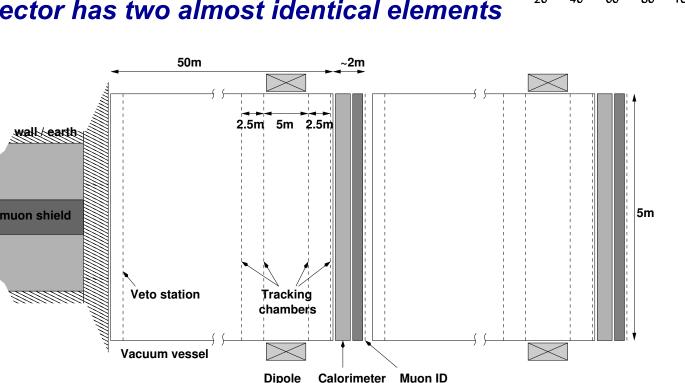

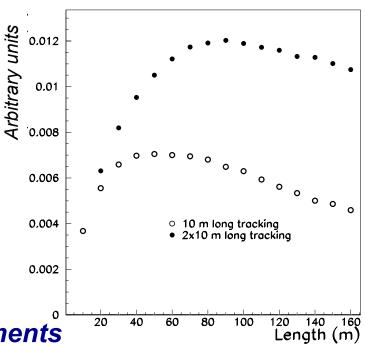

Detector concept (cont.)

Geometrical acceptance

- Saturates for a given HNL lifetime as a • function of detector length
- The use of two magnetic spectrometers • increases the acceptance by 70%

Detector has two almost identical elements

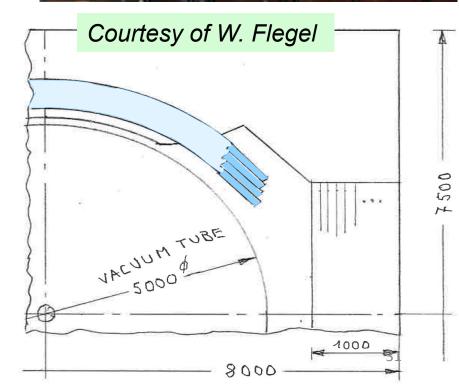

Detector apparatus based on existing technologies

- Experiment requires a dipole magnet similar to LHCb design, but with ~40% less iron and three times less dissipated power
- Free aperture of ~ 16 m² and field integral of ~ 0.5 Tm
 - Yoke outer dimension: 8.0×7.5×2.5 m³
 - Two Al-99.7 coils
 - Peak field ~ 0.2 T
 - Field integral ~ 0.5 Tm over 5 m length

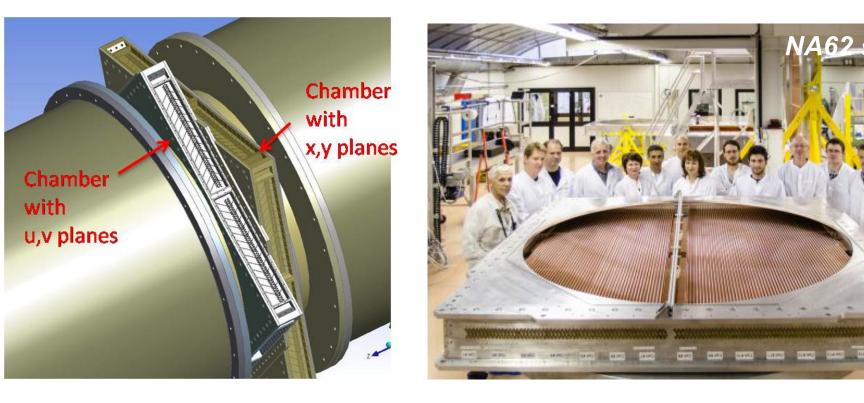

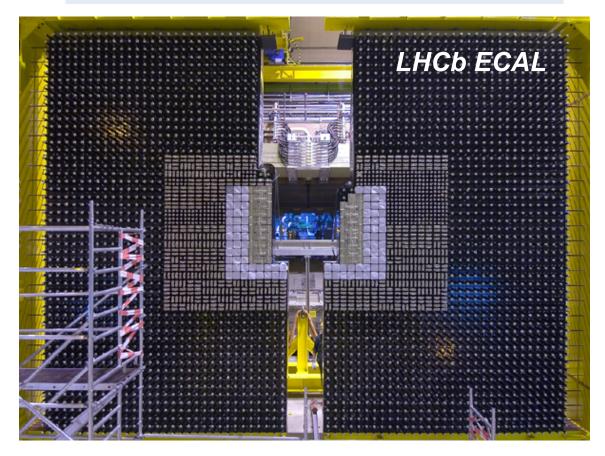

Detector apparatus (cont.) based on existing technologies

NA62 vacuum tank and straw tracker

- < 10⁻⁵ mbar pressure in NA62 tank
- Straw tubes with 120 μm spatial resolution and 0.5% X₀/X material budget Gas tightness of NA62 straw tubes demonstrated in long term tests

Detector apparatus (cont.) based on existing technologies

LHCb electromagnetic calorimeter

- Shashlik technology provides economical solution with good energy and time resolution

Residual backgrounds

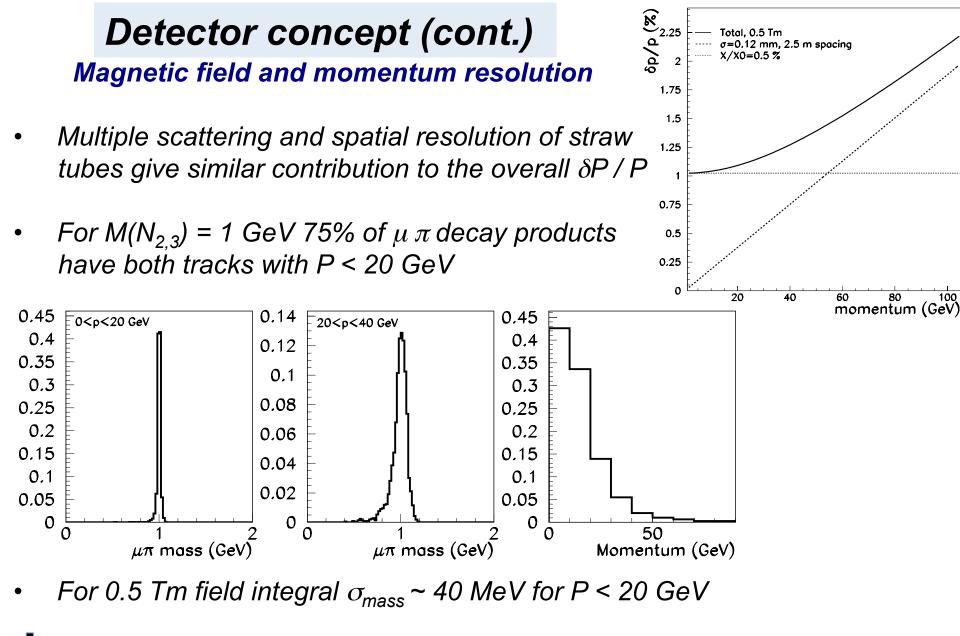

Use a combination of GEANT and GENIE to simulate the Charged Current and Neutral Current neutrino interaction in the final part of the muon shield (cross-checked with CHARM measurement)

yields CC(NC) rate of ~6(2)×10⁵ per int. length per 2×10²⁰ pot

Instrumentation of the end-part of the muon shield would allow the rate of CC + NC to be measured and neutrino interactions to be tagged

- ~10% of neutrino interactions in the muon shield just upstream of the decay volume produce Λ or K⁰ (as follows from GEANT+GENIE and NOMAD measurement)
- *Majority of decays occur in the first 5 m of the decay volume*
- Requiring μ -id. for one of the two decay products

 \rightarrow 150 two-prong vertices in 2×10²⁰ pot

Ample discrimination between high mass tail from small number of residual $K_{I} \rightarrow \pi^{+}\mu^{-}v$ and 1 GeV HNL

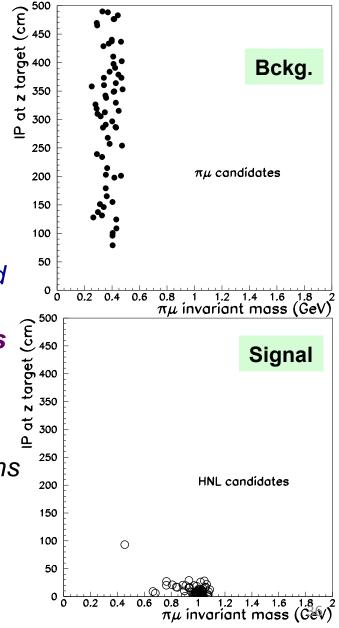

Detector concept (cont.)

Impact Parameter resolution

K_L produced in the final part of the muon shield have very different pointing to the target compared to the signal events

> Use Impact Parameter (IP) to further suppress K_L background

- IP < 1 m is 100% eff. for signal and leaves only a handful of background events
- The IP cut will also be used to reject backgrounds induced in neutrino interactions in the material surrounding the detector

Expected event yield

- Integral mixing angle U^2 is given by $U^2 = U_e^2 + U_{\mu}^2 + U_{\tau}^2$
- A conservative estimate of the sensitivity is obtained by considering only the decay $N_{2,3} \rightarrow \mu^- \pi^+$ with production mechanism $D \rightarrow \mu^+ NX$, which probes U_{μ}^{2}
- $U^2 \longleftrightarrow U_{\mu}^2$ depends on flavour mixing
- Expected number of signal events:

 $N_{signal} = n_{pot} \times 2\chi_{cc} \times BR(U_{\mu}^{2}) \times \varepsilon_{det}(U_{\mu}^{2})$

$$n_{pot} = 2 \times 10^{20}$$

 $\chi_{cc} = 0.45 \times 10^{-3}$

 $BR(U_{\mu}^{2}) = BR(D \rightarrow N_{2,3}X) \times BR(N_{2,3} \rightarrow \mu\pi)$ BR(N_{2,3} $\rightarrow \mu^{-}\pi^{+}$) is assumed to be 20%

 ε_{det} (U_{μ}^{2}) is the probability of the $N_{2,3}$ to decay in the fiducial volume and μ , π are reconstructed in the spectrometer

Expected event yield (cont.)

Assuming $U_{\mu}^{2} = 10^{-7}$ (corresponding to the strongest experimental limit currently for $M_{N} \sim 1$ GeV) and $\tau_{N} = 1.8 \times 10^{-5}$ s

~12k fully reconstructed N $\rightarrow \mu^{-}\pi^{+}$ events are expected for M_{N} = 1 GeV

120 events for cosmologically favoured region: $U_{\mu}^{2} = 10^{-8} \& \tau_{N} = 1.8 \times 10^{-4} s_{38}$

Expected event yield (cont.)

- ECAL will allow the reconstruction of decay modes with π^0 such as $N \rightarrow \mu^- \rho^+$ with $\rho^+ \rightarrow \pi^+ \pi^0$, doubling the signal yield
- Study of decay channels with electrons such as $N \rightarrow e\pi$ would further increase the signal yield and constrain U_e^2

In summary, for $M_N < 2$ GeV the proposed experiment has discovery potential for the cosmologically favoured region with $10^{-7} < U_{\mu}^{2} < a$ few × 10⁻⁹

Status of the SPSC review

- Oct 2013: submitted our EOI: CERN-SPSC-2013-024 ; arXiv:1310.1762 ; SPSC-EOI-010. 2013
- SPSC assigned 4 referees, who came with a list of questions.
- 3/1/2014: answers to questions: snoopy.web.cern.ch/snoopy/EOI/SPSC-EOI-010_ResponseToReferees.pdf
- 15/1/2014: SPSC discussed our proposal.

17/1/2014: The official feedback from the Committee is as follows :

"The Committee received with interest the response of the proponents to the questions raised in its review of EOI010.

The SPSC **recognises** the interesting physics potential of searching for heavy neutral leptons and investigating the properties of neutrinos.

Considering the large cost and complexity of the required beam infrastructure as well as the significant associated beam intensity, such a project should be designed as a general purpose beam dump facility with the broadest possible physics programme, including maximum reach in the investigation of the hidden sector.

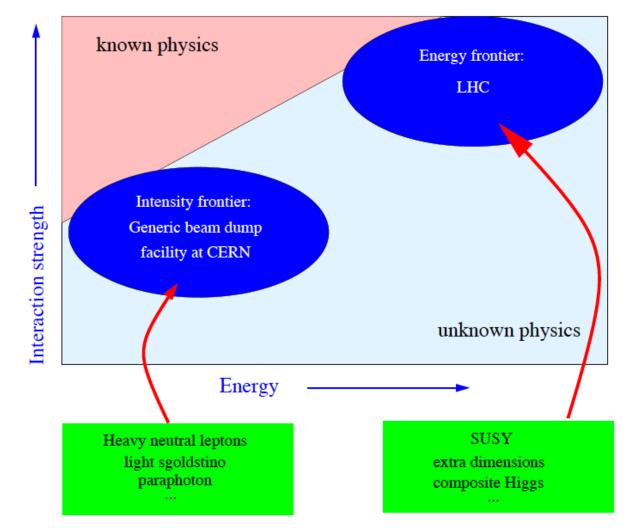

To further review the project the Committee **would need** an extended proposal with further developed physics goals, a more detailed technical design and a stronger collaboration."

Cheers,

Gavin, Lau, Matthew and Thierry

(for the SPS Committee).

Widen physics case at general beam dump facility

Widen physics case at general beam dump facility

✓ Study of v_{τ} interactions

Ideally suited since v_{τ} is produced in $D_s \rightarrow \tau v_{\tau}$ with similar to HNL kinematics

 Search for any weakly interacting yet unstable particles produced in very rare charm (or hyperon) decays such as low mass SUSY or paraphotons or ...

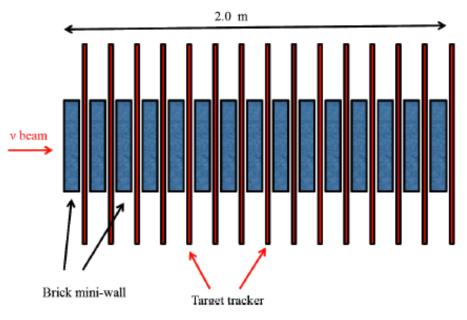

Review of models with hidden sectors is currently underway

We are preparing MC simulations for evaluation of sensitivities for various models

SM physics

 ν_{τ} Physics with 2×10^{20} pot

- Scaling from DONUT: 20 times more CC with same ν -target mass.
- But can increase u-target mass "easily", lets say to 3~% of OPERA emulsion surface:

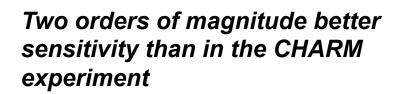

- Only requires limited space along beam-line, hence "no" loss for HNL acceptance.
- HNL spectrometer is forward spectrometer of ν -physics program.
- ν -target allows to tag K_L which coincide with ν -interactions.
- Expect 1500-2000 CC ν_{τ} interactions.
- In addition: $5 \times \nu_{\mu}$ CC charm production than CHORUS (2k).

Examples of BSM physics

Search for light, very weakly interacting, yet unstable New Particles

Massive paraphotons, p (in secluded Dark Matter models), e.g. $\Sigma \rightarrow pV$ with $V \rightarrow \mu\mu$

M. Pospelov, A. Ritz, M.B. Voloshin (2008)

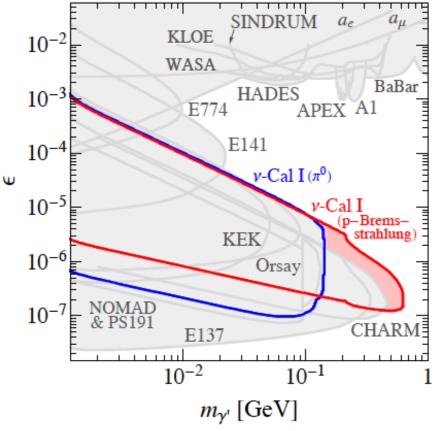

Figure 1: Present direct limits on the model parameter space $(\epsilon, m_{\gamma'})$, for details and original references see [36].

Examples of BSM physics

Search for light, very weakly interacting, yet unstable New Particles

Light s-goldstinos (super-partners of SUSY goldstinos), e.g. $D \rightarrow \pi X$ with $X \rightarrow \mu \mu$

D.S. Gorbunov (2001)

$$N_{\pi^+\pi^-} \simeq 2 \times \left(\frac{1000 \text{ TeV}}{\sqrt{F}}\right)^8 \left(\frac{M_{\lambda_g}}{3 \text{ TeV}}\right)^4 \left(\frac{m_X}{1 \text{ GeV}}\right)^2$$

R-parity violating neutralinos in SUSY goldstinos, e.g. $D \rightarrow \mu \bar{\chi}_0$ with $\bar{\chi}_0 \rightarrow \mu^+ \mu^- \nu$

A. Dedes, H.K. Dreiner, P. Richardson (2001)

$$N \simeq 20 \times \left(\frac{m_{\chi_0}}{1 \text{ GeV}}\right)^6 \left(\frac{\lambda}{10^{-8}}\right)^2 \left(\frac{\text{Br}\left(D \to \chi_0 + \ldots\right)}{10^{-10}}\right)$$

Tracking chambers

Experiment to search for Heavy Neutral Leptons at the SPS

We propose a new fixed-target experiment at the CERN SPS accelerator to search for *hidden particles*. In particular, to search for Heavy Neutral Leptons (HNLs) produced in charm decays. HNLs are right-handed partners of the Standard Model neutrinos. The existence of such particles is strongly motivated by theory, as they can simultaneously explain the baryon asymmetry of the Universe, account for the pattern of neutrino masses and oscillations, and provide a Dark Matter candidate.

SHIP is a collaboration of six institutes: CERN, Universität Zürich, École Polytechnique Fédérale de Lausanne, INFN Sezione di Cagliari, Università Federico II and INFN Napoli, Imperial College London. Groups interested in joining should contact <u>Andrey Golutvin</u> and <u>Jaap Panman</u>. The extension of the collaboration will be discussed at the <u>First SHIP Workshop</u> that will be take place in **Zürich the 10-12 June 2014**.

First SHIP Workshop, 10-12 June 2014, Zürich

Day 1-2	Day 1-2 (Tuesday 10 June)			Objectives of the meeting:	
Status of SM and BSM physics Overview of possible general SPS fixed target	proportioe	 Session 4: Higgs, axion and vector portals Overview of portals to hidden sectors Scalars and pseudoscalars Dark photons 19:00: Dinner 21:00 - : Bar- storming discussion 	Day 2 (We	 Overview of NP within the reach of SHIP Discussion on the detector requirements and technologies

Collaboration matters Summary and next steps

Conclusion and Next steps

- The proposed experiment will search for NP in the largely unexplored domain of new, very weakly interacting particles with masses below the Fermi scale
- Detector is based on existing technologies Ongoing discussions of the beam lines with experts
- The impact of HNL discovery on particle physics is difficult to overestimate !
- The proposed experiment perfectly complements the searches for NP at the LHC and in neutrino physics

A collaboration is currently being setup with aim for the first collaboration meeting in June. Let us know if you are interested to join !
