HEP Seminar, CPPM, Marseille, May 26, 2014

Probing the Higgs Sector from the Top

Aurelio Juste ICREA/IFAE, Barcelona

Today's Presentation

- Motivation for top-Higgs Yukawa coupling measurement
- Light overview of t̄H production at colliders
- Review of ttH searches at LHC Run 1
 - H→bb/ττ
 - Multileptons
 - H→γγ
- ttH Prospects at the LHC and the LC
- Summary

Motivation

- After the discovery of h(125), the focus is on the precise measurement of its properties, in particular couplings to fermions and gauge bosons.
- The top quark is the most strongly-coupled SM particle to the Higgs boson.

For $m_t=173$ GeV:

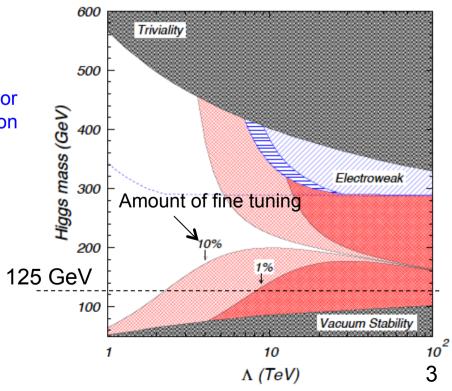

The particle to the Higgs boson. For
$$m_t$$
=173 GeV:
$$\lambda_t = \frac{\sqrt{2}m_t}{v} = 0.996 \pm 0.005$$

$$(125 \, \text{GeV})^2 = m_{H0}^2 + \left[-(2 \, \text{TeV})^2 + (700 \, \text{GeV})^2 + (500 \, \text{GeV})^2 \right] \left(\frac{\Lambda}{10 \, \text{TeV}} \right)^2$$

- → Only quark with a "natural mass".
- → Main responsible for instability of Higgs mass against radiative corrections.

Either New Physics appears at a scale Λ or there has to be a very delicate cancellation

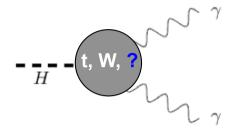

- → May either play a key role in EWSB, or serve as a window to New Physics related to EWSB which might be preferentially coupled to it.
- Big incentive to measure top Yukawa coupling as precisely as possible!

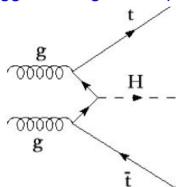

Motivation

Higgs production p

Higgs decay to photons

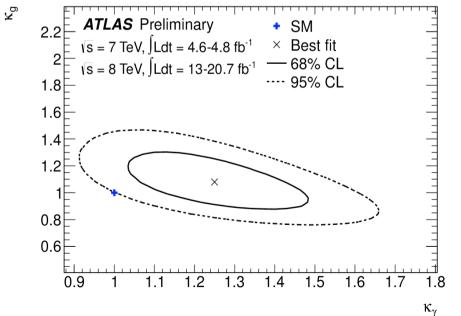

Higgstrahlung from top quark

H

- Indirect constraints on the top-Higgs Yukawa coupling can be extracted from channels involving the ggH and γγH vertices
 - → assumes no new particles.
- Top-Higgs only Yukawa coupling that can be measured directly:

$$\sigma(t\bar{t}H) \propto g_{_{HH}}^2$$

 \rightarrow allows probing for NP contributions in the ggH and $\gamma\gamma$ H vertices.

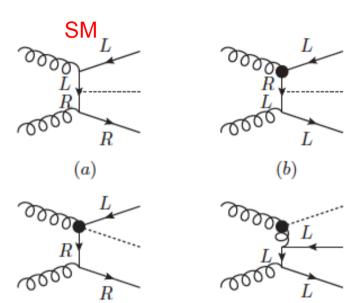

Motivation

- Higher-dimension operators that involve the top and Higgs fields:
 - are little tested so far, and
 - are particularly sensitive to New Physics associated with EWSB.
- Effective top-Higgs Yukawa coupling can deviate from SM prediction due to contributions from dimension-6 operators.

Example: $\sigma(ttH)$ at $\sqrt{s}=14$ TeV:

$$\frac{\sigma\left(pp \to t\bar{t}h\right)}{\text{fb}} = \begin{pmatrix} 611_{-110}^{+92} + \left[457_{-91}^{+127}\Re c_{hg} - 49_{-10}^{+15}c_{G}\right] \\ + 147_{-32}^{+55}c_{HG} - 67_{-16}^{+23}c_{y}\right] \left(\frac{\text{TeV}}{\Lambda}\right)^{2} \\ + \left[543_{-123}^{+143}(\Re c_{hg})^{2} + 1132_{-232}^{+323}c_{G}^{2} \\ + 85.5_{-21}^{+73}c_{HG}^{2} + 2_{-0.5}^{+0.7}c_{y}^{2} \\ + 233_{-144}^{+81}\Re c_{hg}c_{HG} - 50_{-14}^{+16}\Re c_{hg}c_{y} \\ - 3.2_{-8}^{+8}\Re c_{Hy}c_{HG} - 1.2_{-8}^{+8}c_{H}c_{HG}\right] \left(\frac{\text{TeV}}{\Lambda}\right)^{4}$$

arXiv:1205.1065

Complementary to gg→H and tt̄ cross section measurements, which are sensitive to a different combination of operators.

ttH Production in pp Collisions

- ttH production has the lowest cross section for a SM-like Higgs boson at LHC.
- Interestingly, the phase-space suppression effect is overcome at √s>30-40 TeV, where t̄tH becomes the 3rd most important production mechanism.

For M_H =125 GeV:

 \sqrt{s} =7 TeV: $\sigma(t\bar{t}H)$ =86 fb

 \sqrt{s} =8 TeV: $\sigma(t\bar{t}H)$ =130 fb

 \sqrt{s} =14 TeV: $\sigma(t\bar{t}H)$ =611 fb

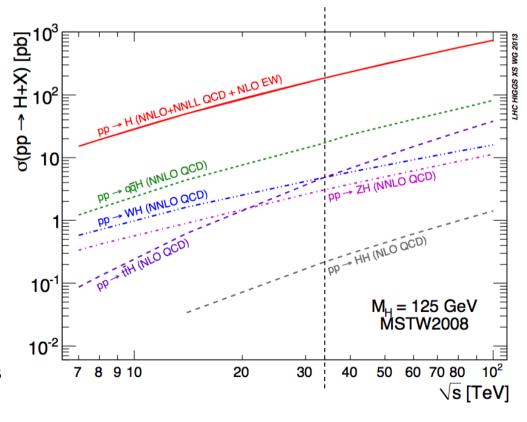

(~x5 wrt \sqrt{s} =8 TeV)

Uncertainties:

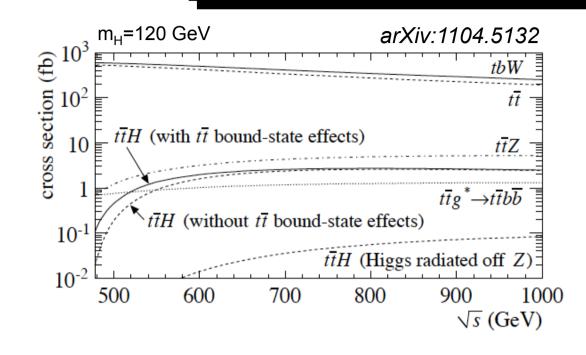

+5.9%/-9.3% (scale), ±8.9% (PDF)

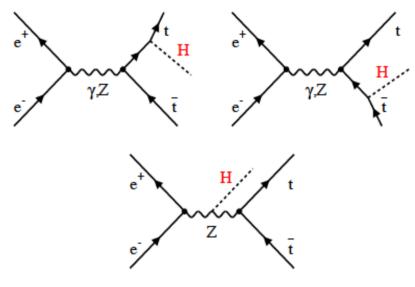

Adds a ~8% uncertainty to the top-Higgs Yukawa. Will need to be improved!

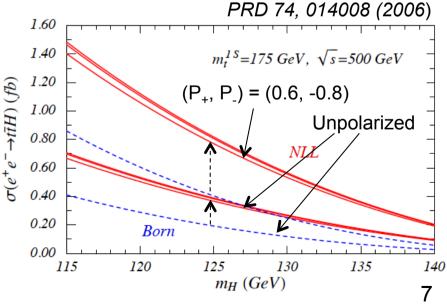

ttH Production in e⁺e⁻ Collisions

- The optimal √s to extract the top-Higgs Yukawa coupling at an e⁺e⁻ collider is ~800 GeV.
- At \sqrt{s} =500 GeV, barely enough phase-space and $\sigma(t\bar{t}H)$ significantly reduced by radiative effects in initial state (ISR, beamstrahlung).

 Fortunately, there are a couple of x2 gains possible
- - tt bound-state effects near threshold
 - beam polarization
- Still, challenging: $\sigma(t\bar{t}H) \le 1$ fb for M_H=125 GeV.

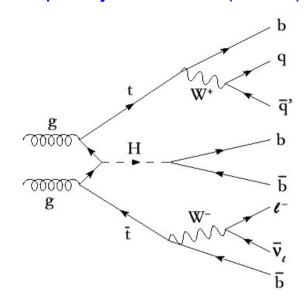

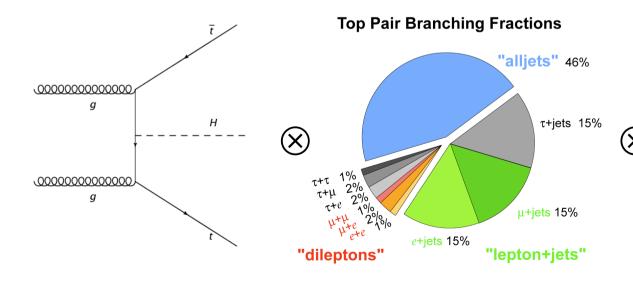

Direct Searches for ttH Production

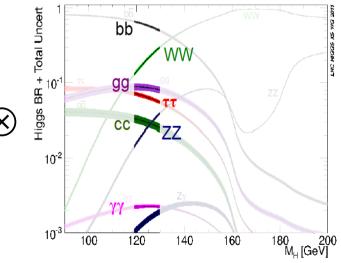

Virtues:

- Distinctive final states with high jet/b-tag multiplicity and multiple heavy resonances
 - A priori many handles against backgrounds!
- For M_H=125 GeV, H \rightarrow b \bar{b} dominates, although other decay modes can also be exploited: H \rightarrow $\tau^+\tau^-$, W⁺W⁻, ZZ, and even $\gamma\gamma$!
- Many possible final states to consider!
 Need to find the best combinations of top and Higgs decays to isolate the signal.

Lepton+jets channel (H→bb̄)

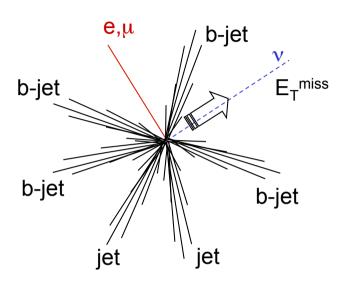

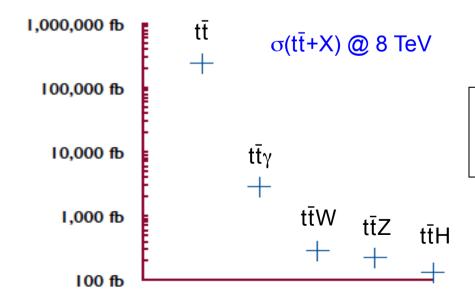

Direct Searches for ttH Production

Challenges:

- Low production cross section.
- H→bb̄, τ⁺τ⁻: large combinatorial and physics backgrounds (mainly t̄t+jets), affected by large systematic uncertainties.
- H→W⁺W⁻, ZZ: typically focus on multilepton final states, which have smaller backgrounds but also small signal rate.
- H→γγ: small signal rate.

Lepton+jets channel (H→bb̄)

Cross section ratio for M_H =125 GeV:

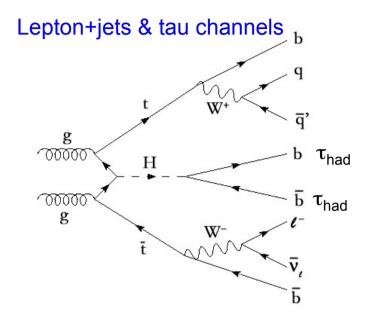

LHC: $\sigma(t\bar{t})/\sigma(t\bar{t}H)\sim 2000(1500)$ for $\sqrt{s}=7$ TeV(14 TeV)

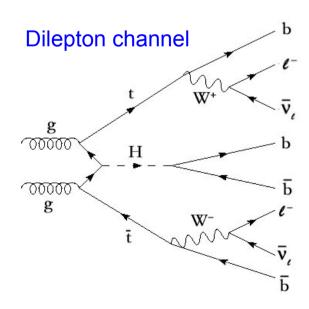

LC: $\sigma(t\bar{t})/\sigma(t\bar{t}H)\sim 500(100)$ for $\sqrt{s}=500$ GeV(1 TeV)

ttH, H→bb/ττ

Basic Analysis Strategy

- Select tt-enriched samples:
 - Lepton+jets and OS dilepton (ATLAS, CMS)
- Pick signals being targeted:
 - $H \rightarrow b\bar{b}$ (ATLAS, CMS), $H \rightarrow \tau\tau$ (CMS).
- Categorize events by jet and b-tag multiplicities:
 - Improve sensitivity by keeping separate high and low S/√B channels.
 - Signal-depleted channels will be exploited to constrain systematic uncertainties.
- For each analysis channel, choose a discriminant variable:
 - ATLAS: single kinematic variable or multivariate discriminant
 - CMS: multivariate discriminant
- Hypothesis testing including in-situ constraining of systematic uncertainties.

Event Selections

"Signal-rich" categories

Lepton+jets channel

=1 isolated e or μ , $p_T>25$ GeV

 \geq 4 jets, p_T>25 GeV (anti-k_T R=0.4)

≥ 2 b-tags

No E_T^{miss} or $m_{T,W}$ requirements

=1 isolated e or μ , $p_T>30$ GeV

 \geq 4 jets, p_T>30 GeV (anti-k_T R=0.5)

 \geq 3 jets, p_T>40 GeV

≥ 2 b-tags

No E_T^{miss} or m_{T,W} requirements

Divide into 9 categories:

4 jets (2, 3, ≥ 4 b-tags),

5 jets (2, 3, ≥ 4 b-tags)

≥ 6 jets (2, <mark>3, ≥ 4 b-tags</mark>)

Divide into 7 categories:

4 jets (3, ≥ 4 b-tags)

5 jets ((3, ≥ 4 b-tags)

≥ 6 jets (2, <mark>3, ≥ 4 b-tags</mark>)

Event Selections

Dileptons channel

"Signal-rich" categories

ee, $\mu\mu$, e μ final states lepton p_T>25/15 GeV

 \geq 2 jets, p_T>25 GeV (anti-k_T R=0.4)

≥ 2 b-tags

ee, μμ, eμ final states tight/loose lepton, p_T>20/10 GeV

 \geq 2 jets, p_T>30 GeV (anti-k_T R=0.5)

≥ 2 b-tags

Divide into 6 categories:

2 jets (2 b-tags)

3 jets (2, 3 b-tags)

≥ 4 jets (2, 3, ≥ 4 b-tags)/

Divide into 3 categories:

3 jets (2 b-tags)

≥ 4 jets (2 b-tags) √

≥ 3 jets (≥ 3 b-tags)

Tau channel

=1 isolated e or μ , $p_T>30$ GeV and

 \geq 2 1-prong τ_{had} , p_T>20 GeV

 \geq 2 jets, p_T>30 GeV (anti-k_T R=0.5)

1 or 2 b-tags

Divide into 6 categories:

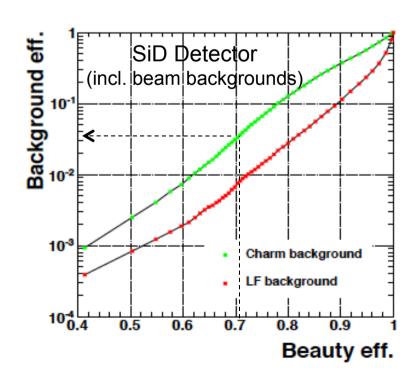

2 jets (1, 2 b-tags)

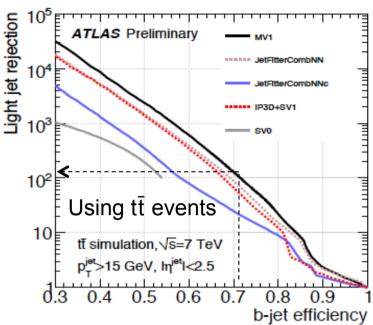

3 jets (1, 2 b-tags)

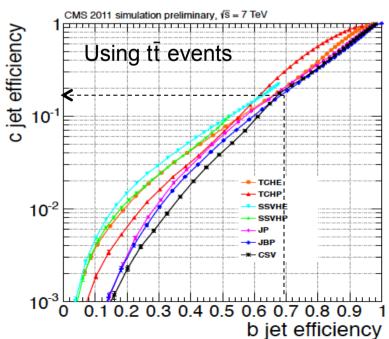

≥ 4 jets (1, 2 b-tags)

B-Jet Identification

- Using multivariate techniques combining information from:
 - Lifetime: displaced tracks and/or vertices
 - Mass: secondary vertex mass
 - Decay chain reconstruction and calibrated in data control samples.
- Performance at LHC: $\varepsilon_b \sim 70\%$, $\varepsilon_c \sim 20\%$, $\varepsilon_{light} \sim 1\%$.
- Much better b-to-c discrimination at a LC.
 - → Important to suppress non-tt̄bb̄ background!

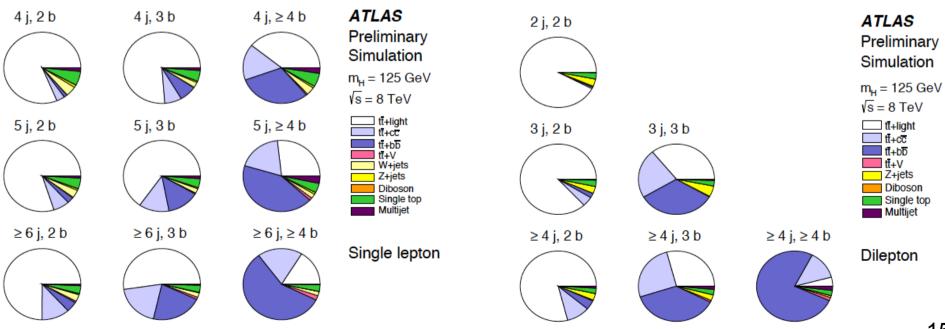

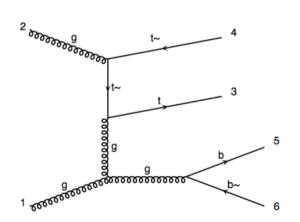

Signal and Background Modeling

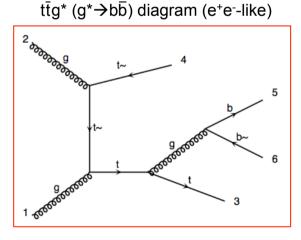

- ttH Signal: POWHEL+PYTHIA (ATLAS), PYTHIA (CMS)
- Backgrounds:
 - tt+jets: POWHEG+PYTHIA (ATLAS), MADGRAPH+PYTHIA (CMS)
 - ttW, ttZ: MADGRAPH+PYTHIA
 - W/Z/γ*+jets: ALPGEN+PYTHIA (ATLAS), MADGRAPH+PYTHIA (CMS)
 - Single top: POWHEG+PYTHIA/AcerMC+PYTHIA (ATLAS), POWHEG+PYTHIA (CMS)
 - Dibosons: *ALPGEN+H*(ATLAS), *PYTHIA* (CMS)
 - Multijets: normalization and shape data-driven
- After requiring ≥1 b-tag background dominated by tt̄.

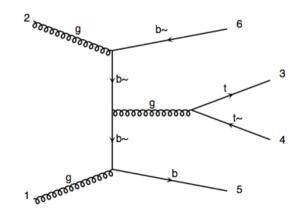

tī+jets Modeling

- Based on matrix element (ME)+parton shower (PS) MCs.
 Inclusive tt+jets samples normalized to approx NNLO cross section.
- MADGRAPH+PYTHIA → used by CMS
 - Separate samples for tt+n partons (n≤3), including heavy quarks (5F scheme).
 - Matched samples. Heavy-flavor overlap removal automatically handled.
- POWHEG+PYTHIA → used by ATLAS
 - Good modeling of tt+jets production, including jet multiplicity and kinematics.
 - Modeling of tt+HF comparable (in normalization and kinematics) to MADGRAPH.
- Even at LO, tt̄bb̄ has many diagrams (36 diags for gg→tt̄bb̄, 7 diags for qq→tt̄bb̄)!
 Examples:

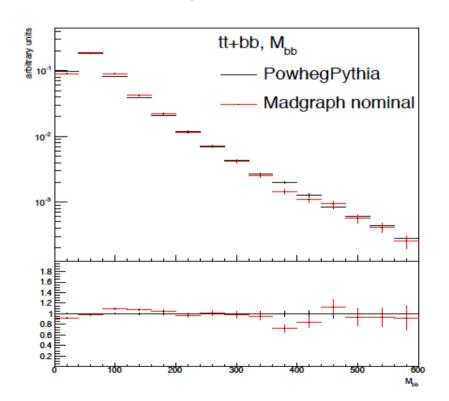

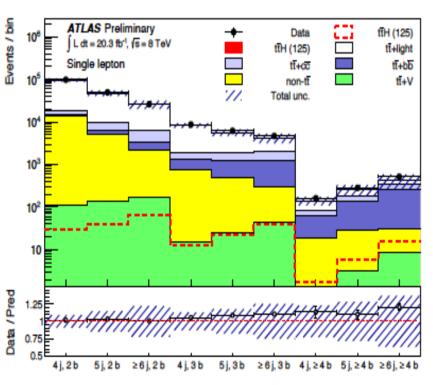

In comparison, only 8 diagrams for e⁺e⁻→tt̄bb̄.

Expect tt̄bb̄ fraction in tt̄+jets to be larger at the LHC!

tī+jets Modeling

- Based on matrix element (ME)+parton shower (PS) MCs.
 Inclusive tt+jets samples normalized to approx NNLO cross section.
- MADGRAPH+PYTHIA → used by CMS
 - Separate samples for tt+n partons (n≤3), including heavy quarks (5F scheme).
 - Matched samples. Heavy-flavor overlap removal automatically handled.
- POWHEG+PYTHIA → used by ATLAS
 - Good modeling of tt+jets production, including jet multiplicity and kinematics.
 - Modeling of tt+HF comparable (in normalization and kinematics) to MADGRAPH.

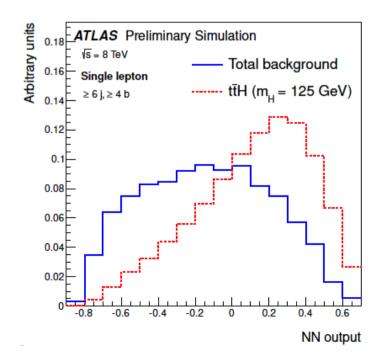

tī+jets Modeling

- Based on matrix element (ME)+parton shower (PS) MCs.
 Inclusive tt+jets samples normalized to approx NNLO cross section.
- MADGRAPH+PYTHIA → used by CMS
 - Separate samples for tt+n partons (n≤3), including heavy quarks (5F scheme).
 - Matched samples. Heavy-flavor overlap removal automatically handled.
- POWHEG+PYTHIA → used by ATLAS
 - Good modeling of tt+jets production, including jet multiplicity and kinematics.
 - Modeling of tt+HF comparable (in normalization and kinematics) to MADGRAPH.
- Modeling further improved by applying MC corrections based on differential cross section measurements (e.g. ATLAS: as a function of top p_T and $t\bar{t}$ p_T ; ATL-CONF-2013-099).
- Overall rate of tt+bb and tt+cc calibrated to data using background-enriched bins in signal-rich regions.

Signal-to-Background Discrimination

- Signal-depleted regions: use $H_T^{had} = \sum p_T^{jets}$ for $\ell+$ jets and $H_T = \sum p_T^{jets} + \sum p_T^{\ell}$ for dilepton
- ℓ +jets, 5 jets, 3 b-tags region: use NN trained to separate $t\bar{t} + b\bar{b}/c\bar{c}$ from $t\bar{t}$ +light jets
- Signal-rich regions: use NN trained to separate $t\bar{t}H$ from $t\bar{t}+{\rm jets}$ in each of the region

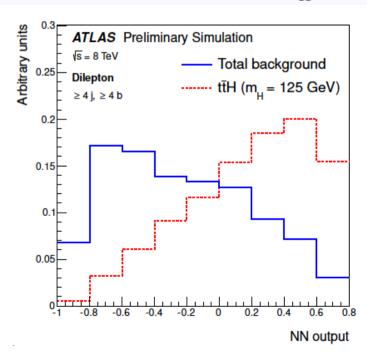

Lepton+iets ATLAS-CONF-2014-011

	2 <i>b</i> -tags	3 <i>b</i> -tags	≥ 4 <i>b</i> -tags
4 jets	H_T^{had}	H_T^{had}	H_T^{had}
5 jets	H_T^{had}	NN	NN

CMS H→bb/ττ Results (8 TeV)

95% CL limit on $\sigma\!/\sigma_{_{\rm SM}}$

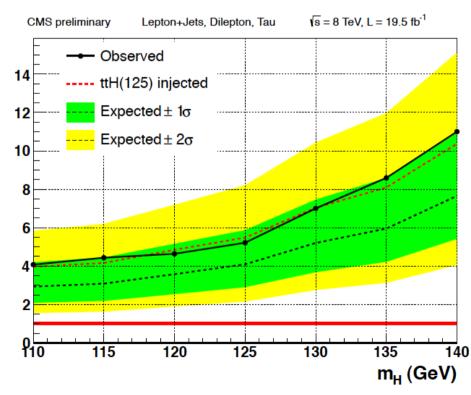

CMS PAS HIG-13-019

- Combination of lepton+jets, dileptons and tau:
 Observed (expected) limit @ M_H=125 GeV:
 5.2xSM (4.1xSM)
- Addition of dilepton and tau channels improves sensitivity by ~15%.

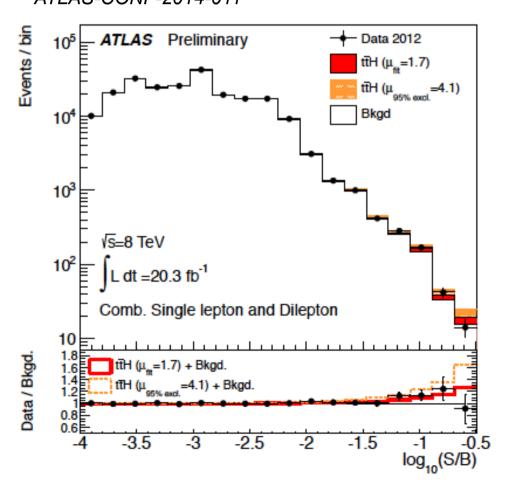

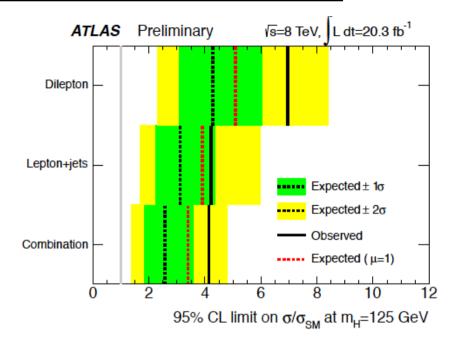

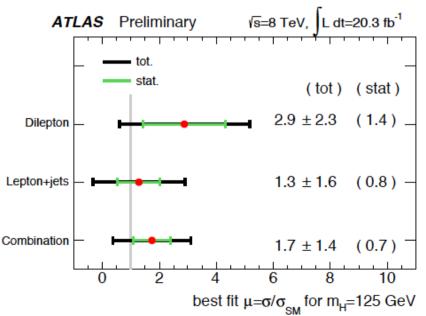

ATLAS H→bb Result (8 TeV)

- Combination of lepton+jets and dileptons:
 Observed (expected) limit @ M_H=125 GeV:
 4.1xSM (2.6xSM)
- Best-fit signal strength: $\mu_{comb} = 1.7 \pm 1.4$

ATLAS-CONF-2014-011

tī+jets Modeling: A Long Road Ahead

<u>Disclaimer:</u> this is my personal view

- The Problem:
 - No good feeling for how accurate current tt+jets/HF ME+PS MCs are.
 - Assigned systematic uncertainties are "ad-hoc". No good understanding for what normalization and shape systematics should be considered and correlations among topologies. Unclear whether we are being too conservative or too aggressive.
 - We'll need a solid quantitative understanding before we can confidently establish a signal in this channel.
- S. Pozzorini: "What's needed to quantify $t\bar{t}$ +jets/HF systematics in a meaningful way and reduce it to a decent (say 10-30%) level is MEPS@NLO $t\bar{t}$ +0,1,2 jets (plus extra LO MEs up to 4,5 jets)."

Current state-of-art

	matrix elements	0j	1j	2j	3j	$\geq 4j$
LO+PS	$t\bar{t} + 2$ jets	-	-	LO	PS	PS
MEPS@LO	$t\bar{t}+0,1,2,3$ jets	LO	LO	LO	LO	PS
MC@NLO	$t\bar{t}+2$ jets	-	-	NLO	LO	PS
MEPS@NLO	$t\bar{t}+0,1,2 \text{ jets}$	NLO	NLO	NLO	LO	PS

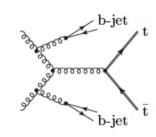

tt+jets Modeling: A Long Road Ahead

 As a first step towads MEPS@NLO, it'd be quite important to perform detailed comparisons of various LO and NLO accurate simulations (w/ PS).

Recent progress:

- First complete MC@NLO simulation (within Sherpa/OpenLoops) for ttbb at the LHC, including mass effects.
- Allows covering the full ttbb phase space at NLO accuracy including collinear g→bb̄ splitting.

Parton-level jets: p_T >25 GeV, $|\eta|$ <2.5, Anti-kT R=0.4 No hadronization. no underlying event

Significant contribution from double collinear $g \rightarrow b\bar{b}$ splitting at high m_{bb} (one of them from the parton shower)

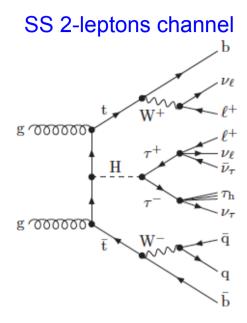

ttH, Multileptons

Basic Analysis Strategy

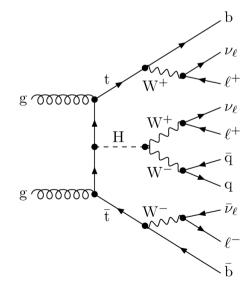

- Mainly probe $H \rightarrow WW$, but also non-negligible contributions from $H \rightarrow \tau\tau$ and $H \rightarrow ZZ$.
- Categorize channels by number of leptons.
 Ideal signatures for H→WW:
 - SS 2-leptons + 6 jets (2 b jets)
 - 3-leptons + 4 jets (2 b jets)
 - 4-leptons + 2 jets (2 b jets)

as leptons.

- Low signal rate but also low background, dominated by t̄tW/Z/γ*.
 Additional contributions from WZ and ZZ.
 For SS 2-lepton and 3-lepton analyses, sizable contribution from t̄t+jets, with jets misidentified
- Use multivariate discriminants to separate signal from backgrounds.

3-leptons channel

Event Selections

SS 2-leptons channel

 $e^{\pm}e^{\pm}$, $\mu^{\pm}\mu^{\pm}$, $e^{\pm}\mu^{\pm}$ final states

2 tight e/μ , $p_T>20$ GeV; Z veto

 \geq 4 jets, p_T>25 GeV (anti-k_T R=0.5)

≥ 2 b-tags

≥ 2 b-tags

E_T^{miss} LD cut if SF/OS pair and <4 jets

4-leptons channel

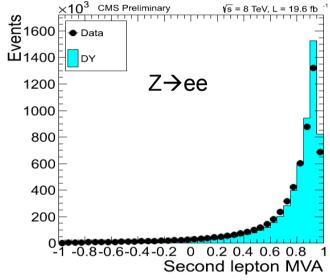

4 loose e/μ , $p_T>20/10/10/10$ GeV; Z veto

 \geq 2 jets, p_T>25 GeV (anti-k_T R=0.5)

≥ 2 b-tags

 MVA-based lepton identification (trained on ttH vs tt+jets MC):

CMS PAS HIG-13-020

Background Estimation

ttV+jets (V=W, Z, WW)

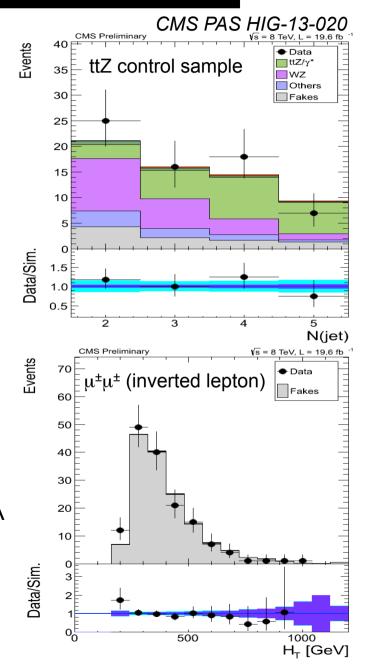

- Predicted using Madgraph+Pythia MC normalized to NLO cros section (~13% uncertainty). Additional uncertainties from varying scale choices in the MC.
- ttZ prediction validated in data control sample (~35% statistical uncertainty).

Dibosons+jets (WZ,ZZ)

- Predicted using Madgraph+Pythia MC calibrated in data control samples (WZ+≥2+non-b jets and ZZ+≥1+non-b jets).
- Total uncertainty ~20% (includes uncertainty in extrapolation from control to signal region).

tt+jets instrumental

- Fake leptons: data events with inverted lepton MVA corrected with per-lepton fake rate. Uncert. ~50%.
- Charge misID (SS 2-leptons): OS 2-leptons data events corrected with per-lepton charged misID rate. Uncert. ~30%.

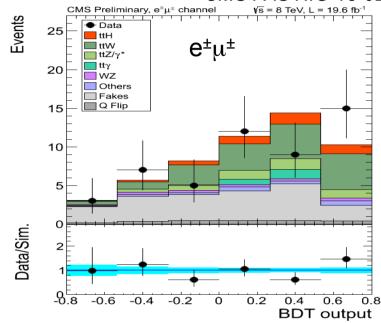

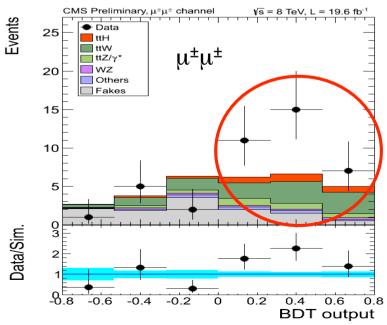

SS 2-Leptons

CMS PAS HIG-13-020

- Analyze separately e[±]e[±], μ[±]μ[±], e[±]μ[±] events.
- Events categorized according to lepton charge sum (exploit charge correlation in ttW).
- BDT trained between ttH signal and tt+jets background MC (6 vars: e.g. H_T).
- ~3σ excess (wrt SM) in μ[±]μ[±] channel.
 Cross-checks performed show no issues with data quality or background mismodeling.

CMS Multilepton Result

CMS PAS HIG-13-020

- Excellent sensitivity of SS 2-leptons and 3-lepton channels!
- Combination of multilepton analyses:

Observed (expected) limit @ M_H=125 GeV: 6.6xSM (2.4xSM)

ttH, H $\rightarrow \gamma \gamma$

Basic Analysis Strategy

- Small BR(H→γγ) is compensated by the much smaller backgrounds and the good diphoton mass resolution.
- Capitalize on well-understood H→γγ analyses.
- Categorize signal events according to the tt
 decay mode (leptonic or hadronic).
 Exploit high jet multiplicity and b-jet content
 of signal to optimize sensitivity.
- Discriminant variable: m_{γγ}
 No need (for now) to estimate complicated background composition. Can perform sideband analysis as in standard H→γγ analyses.

t̄tH, H→γγ Candidate

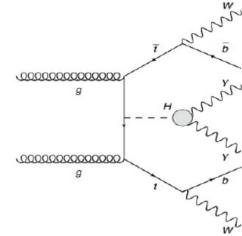

```
2 photons, p_{T1}=61 GeV, p_{T2}=39 GeV

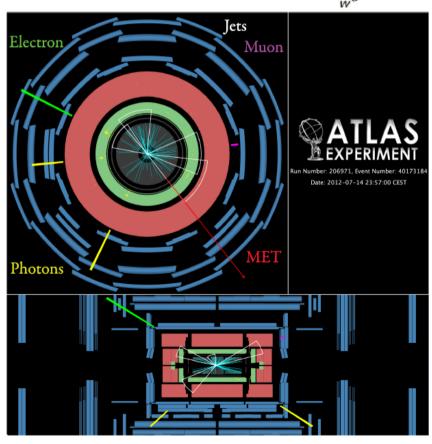

m_{\gamma\gamma}=126.6 GeV

1 electron, p_{T}=90 GeV

E_{T}^{miss} = 43 GeV

4 jets, p_{T}=75, 71, 50, 39 GeV, 1 muon-tagged jet
```

Event Selections

Leptonic channel

2 photons, $p_T>40 / 30 \text{ GeV}$

≥ 1 e/µ, p_T>15/10 GeV

E_Tmiss>20 GeV

≥ 1 jets, p_T>25 GeV

≥ 1 b-tags (80% efficiency)

 \geq 1 e or μ , $p_T>20$ GeV

No E_Tmiss cut

≥ 1 jets, p_T>25 GeV

≥ 1 b-tags (70% efficiency)

Hadronic channel

2 photons, p_T>40/30 GeV

0 leptons

≥ 6 jets, p_T>25 GeV

≥ 2 b-tags (80% efficiency)

2 photons, $p_T > 0.5 m_{yy}/25 \text{ GeV}$

0 leptons

≥ 4 jets, p_T>25 GeV

≥ 1 b-tags (80% efficiency)

High ttH purity selections

			VBF(%)	WH(%)			
Leptonic	0.55	0.6	0.3	7.7	2.4	6.1	82.8
Leptonic Hadronic	0.36	5.3	1.1	1.1	1.3	_	82.8 91.2

Process	Hadronic Channel	Leptonic Channel
$\overline{t}\overline{t}H$	0.567 (87%)	0.429 (97%)
gg o H	0.059~(9%)	0 (0%)
$\mathrm{VBF}\ H$	0.006~(1%)	0 (0%)
WH/ZH	0.019~(3%)	0.013~(3%)
Total signal	0.65	0.44

Background Estimation

- ATLAS: exponential fit to both signal region and control regions with relaxed cuts.
- CMS: exponential (leptonic channel) or 2nd order polynomial (hadronic channel) fit in signal region.

ATLAS H→γγ Result

 Observed (expected) limit @ M_H=126.8 GeV: 5.3xSM (6.4xSM) Limits @ M_H=126.8 GeV

•	Search statistically-limited.
	Small impact from systematic uncertainties,
	in contrast with ttH, H→bb.

	Observed limit	Expected limit
Combined (with systematics)	5.3	6.4
Combined (statistics only)	5.0	6.0
Leptonic (with systematics)	9.0	8.4
Leptonic (statistics only)	8.5	8.0
Hadronic (with systematics)	8.4	13.6
Hadronic (statistics only)	7.9	12.6

• Good signal-to-background:

Channel	N_S	N_B	N_S/N_B
Leptonic	0.55	$1.2^{+0.6}_{-0.5}$	0.45
Hadronic	0.36	$1.9^{+0.7}_{-0.5}$	0.19

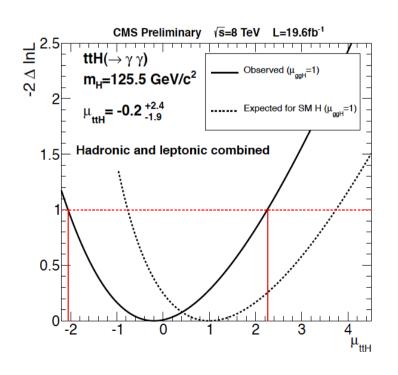

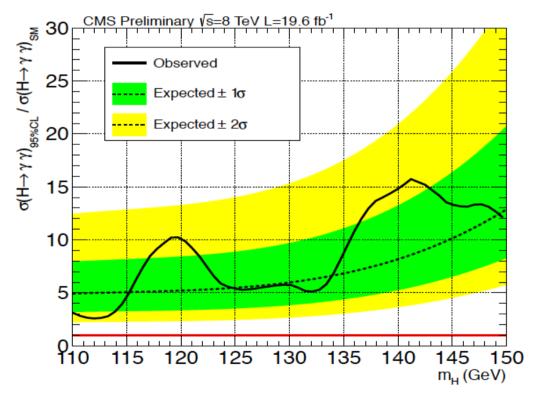

CMS H→γγ Result

 Observed (expected) limit @ M_H=125 GeV: 5.4xSM (5.3xSM) Limits @ M_H=125 GeV

•	Search statistically-limited.
	Small impact from systematic uncertainties,
	in contrast with ttH H→bb

	Observed	Expected	Expected (No Syst.)
Hadronic Channel	6.8	9.2	8.8
Leptonic Channel	10.7	8.0	7.7
Combined	5.4	5.3	5.1

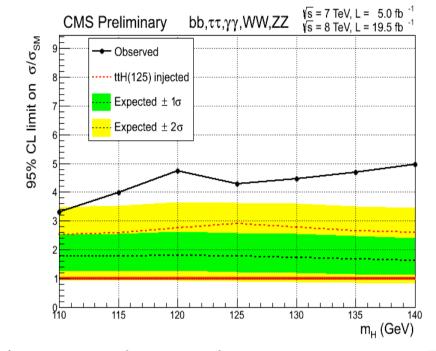

CMS Grand Combination

- Combination of CMS results:
 - H→bb (7 TeV pub + 8 TeV prelim)
 - H $\rightarrow \tau\tau$ (8 TeV prelim)
 - SS 2-lep, 3-lep, 4-lep (8 TeV prelim)
 - $H \rightarrow \gamma \gamma$ (8 TeV prelim)
- Obs (exp) limit @ M_H=125 GeV:
 4.3xSM (1.8xSM).

	Observed	Median Signal Injected	Median
$\gamma\gamma$	5.4	6.7	5.5
$b\bar{b}$	4.5	5.2	$\left \begin{array}{c} \left(3.7 \right) \end{array} \right $
$\tau\tau$	12.9	16.2	14.2
41	6.8	11.9	8.8
31	6.7	4.7	3.8
Same-sign 2l	9.1	3.6	3.4
Combined	4.3	2.9	1.8

Comparable sensitivity of H→bb̄ and multilepton channels!

Prospects

• Feasibility studies at the LC have shown that a precision on the top Yukawa coupling of 10%(5%) can be achieved at $\sqrt{s}=500$ GeV (1 TeV) with 1 ab⁻¹.

However:

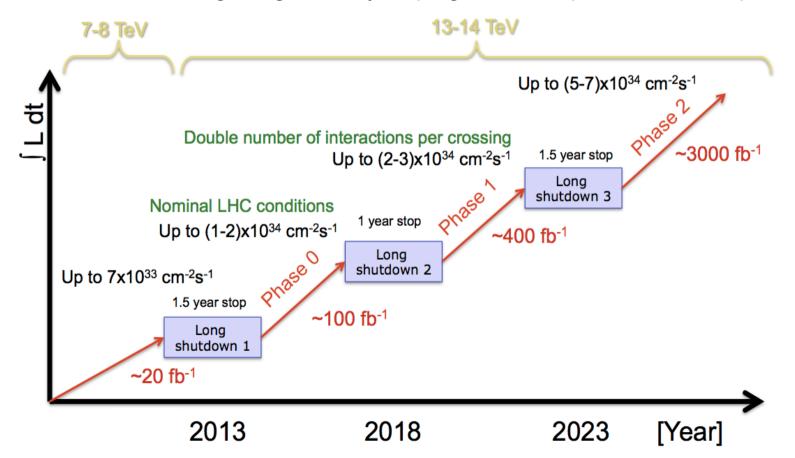

- Studies were largely based on fast simulation and not using ME+PS MCs to predict tt+jets background
- In the best case scenario ad-hoc uncertainties on the background of 5-10% were assigned. Are those justified?

On the bright side, much of the experience and developments necessary to carry out this measurement at the LHC will be beneficial to the ILC:

- Precise theoretical predictions for signal and backgrounds via e.g. MEPS@NLO.
- Profiling of systematic uncertainties.

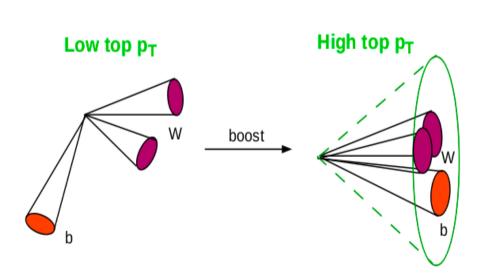

- Can the LHC measure the top-Higgs Yukawa coupling to ~10% or better?
 - A 10% measurement means ~5σ significance.
 - Advanced analysis techniques may resurrect H→bb as a discovery mode.
 - New channels not considered before ($H \rightarrow \gamma \gamma$, multileptons), have irrupted into the scene with surprisingly good sensitivity and have great potential.

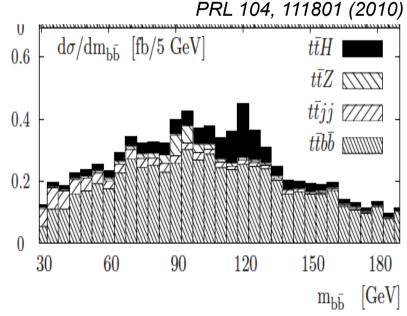

- Short term:
 - ATLAS searches using full Run 1 dataset ongoing in similar channels as for CMS.
 Expect results to be available during Summer 2014.
 - Combination of ATLAS+CMS Run 1 results should be close to SM sensitivity!
- Longer term:
 - We are at the beginning of a 20-year program! Much potential to be exploited.

H→bb

- It has been pointed out that $\sqrt{s}=14$ TeV "boosted" analyses can potentially achieve $\sim 5\sigma$ significance with 100 fb⁻¹.
 - Requiring high enough p_T for hadronic top quark and/or Higgs boson allows to significantly reduce both physics and combinatorial backgrounds.
 - These techniques have by now become "standard" at the LHC experiments in searches for boosted bosons and top quarks.
 - Experimental searches for boosted ttH just starting. "Resolved" and "boosted" analyses will likely co-exists and be combined at the end.

Multilepton (3-leptons and 4-leptons)

- Recently studied in the context of the European Strategy and Snowmass.
- Analysis still statistically limited with 300 fb⁻¹.
- At very high-luminosity (and pileup), sensitivity may be dominated by 4-leptons due to significant contribution from fake leptons in 3-leptons analysis.
- For 3000 fb⁻¹, experimental uncertainty on top Yukawa ~5%.
- Theoretical uncertainty on $\sigma(ttH)$ adds 8% in quadrature!

$H \rightarrow \gamma \gamma$

- Recently studied in the context of the European Strategy and Snowmass.
- Analysis statistically limited.

For 3000 fb⁻¹ at \sqrt{s} =14 TeV:

Expected uncertainty on signal strength ~20%

→ 10% uncertainty on top Yukawa coupling

arXiv:1307.7280

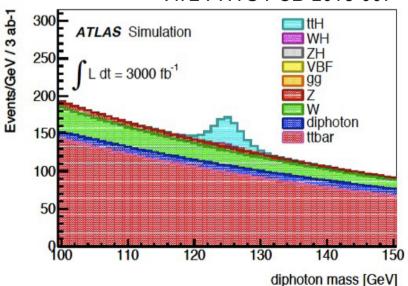

Stat. uncert. on $\sigma(ttH)$

		(/
Channel	300 fb^{-1}	3000 fb^{-1}
3ℓ only	25%	%
4ℓ only	34%	12%
Combined	21%	9%

Syst. uncert. on $\sigma(ttH)$

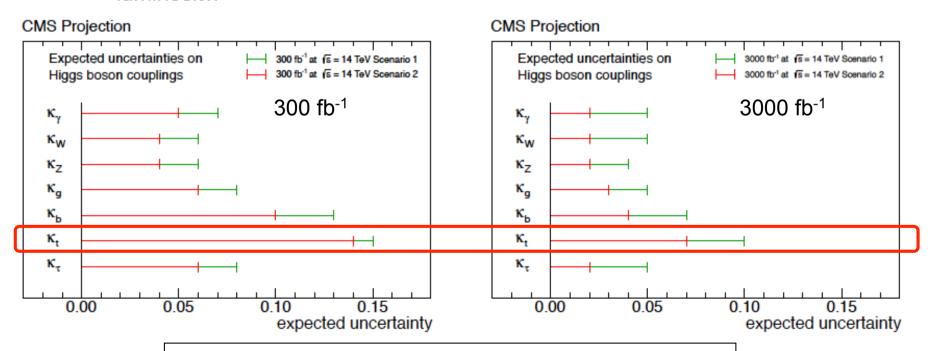

Channel	300 fb ⁻¹	3000 fb ⁻¹			
Top fake rate	17%	2%			
$\sigma(t\bar{t}H)_{\rm SM}$	16%	16%			
Other cross-section systematics	8%	3%			
All systematics	27%	17%			
Systematics without $\sigma(t\bar{t}H)_{\rm SM}$	18%	4%			

ATL-PHYS-PUB-2013-007

Global Fit Analysis arXiv:1307.7135

- Extrapolation of global fit to Higgs couplings based on existing CMS Higgs analyses.
 - ttH: only considering $H \rightarrow \gamma \gamma$ and $H \rightarrow$ bb. Will get better after including multileptons.
- Consider two scenarios:
 - Scenario 1: all systematic uncertainties are left unchanged.
 - Scenario 2: theoretical uncertainties are scaled by a factor of 1/2, while other systematic uncertainties are scaled by the square root of the integrated luminosity.

Tentative conclusion: a ~5-10% uncertainty on the top Yukawa coupling at the LHC may be realistic!

Summary

- The precise measurement of the top Yukawa coupling may provide insights on the underlying mechanism for EWSB and whether or not the top quark plays a role in it.
- The program of searches for t̄tH production at the LHC is well underway, with all main decay modes being explored (H→bb̄, ττ, WW and ZZ).
- H→bb has turned out to be just as challenging as anticipated. Much experience has been gained on how to reduce the impact from systematic uncertainties that led to abandon this channel in the past, by exploiting high-statistics data samples.
 However, further progress is needed on the theoretical description of the dominant tt+jets background. Jet substructure techniques hold great promise in this channel.
- At the same time, searches for ttH in diphoton and multilepton final states are showing interesting sensitivity that can be competitive with (or even exceed) that of H→bb.
- A LHC combination could in principle approach SM sensitivity with the Run 1 datasets.

Exciting prospects for the $\sqrt{s}=13/14$ TeV run!

- Many systematic uncertainties, both theoretical and experimental.
- Background systematics much larger than expected signal yield!

Total background uncertainty: ~37% Expected S/B: ~3.3%

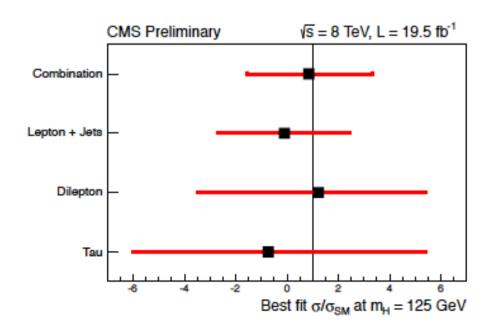

CMS H→bb/ττ Results (7+8 TeV)

95% CL limit on $\sigma\!/\sigma_{_{\rm SM}}$

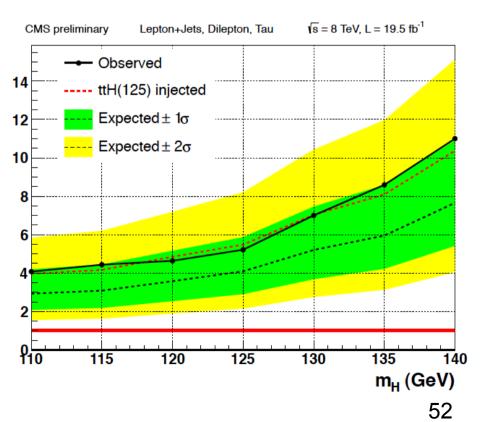

- Observed (expected) limit @ M_H=125 GeV: 5.2xSM (4.1xSM)
- Addition of dilepton and tau channels improves sensitivity by ~15%.
- Analysis not scaling as 1/√L (dominated by tt̄+HF syst., revisited since the previous publication result; arXiv:1303.0763):

Exp. Limit (7 TeV, 5.0 fb⁻¹): 6.9xSM Exp. Limit (8 TeV, 5.1 fb⁻¹): 5.7xSM

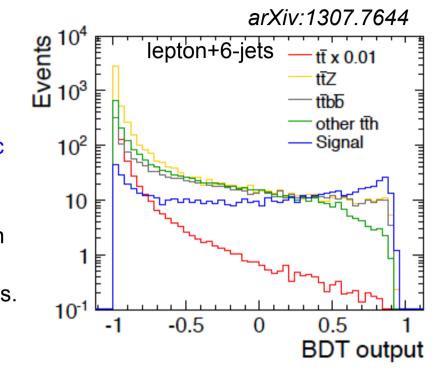

CMS PAS HIG-13-019

ttH decay mode	Ехр	ОЬ
H→bb, tt→lepton+jets	4.7	4.9
H→bb ₁ , tt→dilepton	8.2	9.1
H→tautau, tt→ljets or dilepton	14.2	13.2
Combination	4.1	5.2

- The precise measurement of the top Yukawa coupling has traditionally been considered as something that only the LC could do.
- The most recent feasibility studies are finally based on full simulation and employing realistic reconstruction algorithms.
- Example: ttH, H→bb
 - $\sqrt{s}=1$ TeV, and 1 ab⁻¹ equally split between $(P_{e-}, P_{e+})=(-0.8, +0.2)$ and (+0.8, -0.2)
 - Consider lepton+6-jets and 8-jets channels.
 - Train BDT to separate signal from background.
 - Apply BDT cut to maximize S/√S+B.
 - → Expected stat. error on top Yukawa: 4.5%
- At √s=500 GeV it becomes more challenging:
 - $\sigma(t\bar{t}H)$ down by x10, $\sigma(t\bar{t})$ up by x2.5
 - However, ttH is enhanced by x2 due to tt
 bound effects, and ttH and tt another x2 if
 using beam polarization.
 - → Expected stat. error on top Yukawa: ~10%

After BDT cut	arXiv:1307.7644
Final state	BDT trained to select 6 jets
$t\overline{t}H, H \rightarrow b\overline{b}$ (6 jets)	264.9
$t\overline{t}H, H \rightarrow b\overline{b}$ (8 jets)	72.6
$t\bar{t}H$, H not $b\bar{b}$ (6 jets)	11.7
$t\overline{t}H$, H not $b\overline{b}$ (8 jets)	4.3
ttH (4 jets)	32.8
$t\bar{t}Z$	188.4
