How do we numerically estimate an integral of an arbitrary function $f(\mathbf{x})$?

$$
I=\int_{\Omega}d^{n}\mathbf{x}\,f(\mathbf{x})
$$

Simple discretization (Simpsons rule, Gaussian quadrature) can be extremely inefficient if

- \blacktriangleright *n* is large
- \blacktriangleright Ω is complicated
- \blacktriangleright $f(\boldsymbol{x})$ has peaks and divergencies.

[Importance sampling](#page-4-0) [Obtaining Suitable Random Distributions](#page-7-0) [Predicting an Observable](#page-10-0)

Importance sampling

Assume we are able to generate random variables *Xⁱ* such that

$$
P\left(x^{(j)} < x_i^{(j)} < x^{(j)} + dx^{(j)}\right) = p_X(\mathbf{x})
$$

if $p(x) > 0$, $\forall x \in \Omega$ and zero outside, we can rewrite our integral

$$
I=\int_{\Omega}d^{n}x\frac{f(x)}{p_{X}(x)}p_{X}(x).
$$

Now, for any random variable *Y* and any function *g*, we know that *N*

$$
\frac{1}{N}\sum_{i=1}^N g(Y_i) \approx \langle g(Y) \rangle = \int_{-\infty}^{\infty} dy \, p_Y(y) g(y)
$$

[Monte Carlo Integration](#page-3-0) [The Generic Event Generator](#page-15-0) [Matrix Element Generation](#page-30-0) [Importance sampling](#page-4-0) [Obtaining Suitable Random Distributions](#page-7-0) [Predicting an Observable](#page-10-0)

Hence

$$
\left\langle \frac{f(\boldsymbol{X})}{p_X(\boldsymbol{X})} \right\rangle = \int_{\Omega} d^n \boldsymbol{x} \frac{f(\boldsymbol{x})}{p_X(\boldsymbol{x})} p_X(\boldsymbol{x}) = I
$$

So, we can numerically estimate our integral by generating *N* points \boldsymbol{X}_i and take the average of $f(\boldsymbol{X})/p_{\boldsymbol{X}}(\boldsymbol{X})$.

In doing so we will get an error which we can estimate by

$$
\delta \approx \sigma \left(\frac{f(\mathbf{X})}{p_{\mathbf{X}}(\mathbf{X})} \right) / \sqrt{N}
$$

where the variance is given by $\sigma^2(Y) = \langle Y^2 \rangle - \langle Y \rangle^2$.

[Importance sampling](#page-4-0) [Obtaining Suitable Random Distributions](#page-7-0) [Predicting an Observable](#page-10-0)

Clearly if $p_X(x) = C|f(x)|$, we get the smallest possible error (if $f(x) > 0$ the error is zero).

However, with a bad choice of p_X , the variance and the error need not even be finite.

Numerically generating points directly according to $p_X(\mathbf{x}) = C|f(\mathbf{x})|$ is in general difficult, and typically involves analytically solving the integral we want to estimate. But there are some tricks. . .

[Importance sampling](#page-4-0) [Obtaining Suitable Random Distributions](#page-7-0) [Predicting an Observable](#page-10-0)

Normally we only have uniformly distributed (flat) random numbers available on the computer

$$
p_R(r) = \left\{ \begin{array}{ll} 1 & 0 < r < 1 \\ 0 & \text{otherwise} \end{array} \right.
$$

We can transform any distribution into any other by the a transformation using the cumulative distributions

$$
P_Y(y) = \int_{-\infty}^y dt \, p_Y(t) = \int_{-\infty}^r dt \, p_R(t) = P_R(r)
$$

as long as P_Y^{-1} *Y* (*PR*(*r*)) is a monotonically increasing function.

[Monte Carlo Integration](#page-3-0) [The Generic Event Generator](#page-15-0) [Matrix Element Generation](#page-30-0) [Importance sampling](#page-4-0) [Obtaining Suitable Random Distributions](#page-7-0) [Predicting an Observable](#page-10-0)

If $P_{\rm Y}^{-1}$ $V_Y^{-1}(P_R(r))$ is not monotonous, we can divide up in intervals. What if P_Y^{-1} V_Y^{-1} is hard to find \dots

4日 ト

The Accept/Reject Method

Assume we want to generate random variables, *Yⁱ* , according to some difficult distribution $p_Y(y)$. We already know how to generate according to some other distribution, $p_{Y}(y)$ such that $Cp_{y'}(y) \geq p_Y(y)$ everywhere.

- 1. Generate Y' according to $p_{Y}(y)$
- 2. Generate *R* according to a flat distribution

3. If
$$
\frac{p_Y(Y')}{Cp_{Y'}(Y')} > R
$$
 then accept $Y = Y'$

► otherwise reject Y' and goto 1

The accepted *Y* will be distributed according to $p_Y(y)$. We need 2*C* random numbers to get one *Y*.

4日)

Predicting an Observable

To calculate the expectation value of an observable, \mathcal{O} , in a $pp \rightarrow X$ collision we need to evaluate an integral looking like

$$
\langle \mathcal{O} \rangle = \sum_{n} \sum_{\mathbf{Q}} \int d^{4n} \mathbf{p} \, |\mathcal{M}_n(\mathbf{Q}, \mathbf{p})|^2 \, \mathcal{O}_n(\mathbf{Q}, \mathbf{p}) \, \Phi_n(\mathbf{p})
$$

- **► p** is the momenta of the n particles
- **Q** is their quantum numbers
- \blacktriangleright M is the matrix element
- \blacktriangleright Φ_n is the phase space density etc.

[Monte Carlo Integration](#page-3-0) [The Generic Event Generator](#page-15-0) [Matrix Element Generation](#page-30-0) [Importance sampling](#page-4-0) [Obtaining Suitable Random Distributions](#page-7-0) [Predicting an Observable](#page-10-0)

So now, all we need to do is to find a probability distribution $p(n, \mathbf{Q}, \mathbf{p})$ such that

$$
C p(n, \mathbf{Q}, \mathbf{p}) = |\mathcal{M}_n(\mathbf{Q}, \mathbf{p})|^2 \Phi_n(\mathbf{p})
$$

Then we generate N points, $(n_i, \boldsymbol{Q}_i, \boldsymbol{p}_i)$ according to this and get

$$
\langle \mathcal{O} \rangle = \frac{C}{N} \sum_{i}^{N} \mathcal{O}_n(\mathbf{Q}_i, \mathbf{p}_i)
$$

In the same way as we do when measuring the observable experimentally.

We are generating events. And we can measure several observables in one go. Life is simple!

[Importance sampling](#page-4-0) [Obtaining Suitable Random Distributions](#page-7-0) [Predicting an Observable](#page-10-0)

The First Commandment of Event Generation

Thou shalt never believe event generation is easy

4日下

[Importance sampling](#page-4-0) [Obtaining Suitable Random Distributions](#page-7-0) [Predicting an Observable](#page-10-0)

There are no free lunches

- \blacktriangleright M can typically only be calculated perturbatively to leading and maybe next-to-leading order for a small number of particles.
- \blacktriangleright Φ_n is not trivial
- ightharpoontal finding $p(n, \mathbf{Q}, \mathbf{p})$ may be very difficult

4日 ト

[Importance sampling](#page-4-0) [Obtaining Suitable Random Distributions](#page-7-0) [Predicting an Observable](#page-10-0)

Weighted vs. Unweighted Events

We can, of course use any probability distribution and get

$$
\langle \mathcal{O} \rangle = \frac{C}{N} \sum_{i}^{N} \frac{|\mathcal{M}_n(\mathbf{Q}_i, \mathbf{p}_i)|^2 \Phi_n(\mathbf{p}_i)}{p(n_i, \mathbf{Q}_i, \mathbf{p}_i)} \mathcal{O}_n(\mathbf{Q}_i, \mathbf{p}_i)
$$

which means we get weighted events.

This is OK as long as the variance is not too big.

[Factorization](#page-15-0) [The Generation Steps](#page-17-0) [Everything is QCD](#page-27-0)

$$
\begin{array}{lcl} \langle \mathcal{O} \rangle & = & \displaystyle \sum_{n_1, \mathbf{Q}_q} \int d^{4n_q} \bm{q} \, \left| \mathcal{M}_{n_q}(\bm{Q}_q, \bm{q}) \right|^2 \Phi_{n_q}(\bm{q}) \times \\ & & \left[\displaystyle \sum_{n_k, \mathbf{Q}_k} \int d^{4n_k} \bm{k} \, P S(\bm{Q}_q, \bm{q}; \bm{Q}_k, \bm{k}) \times \\ & & \left\{ \displaystyle \sum_{n_p, \mathbf{Q}_p} \int d^{4n_p} \bm{p} \, H(\bm{Q}_k, \bm{k}; \bm{Q}_p, \bm{p}) \mathcal{O}_{n_p}(\bm{Q}_p, \bm{p}) \right\} \end{array}
$$

- \blacktriangleright M now only gives a few partons
- ► PS is a parton shower giving more partons with unit probability
- \blacktriangleright *H* is hadronization and decays giving final state hadrons with unit probability

[Factorization](#page-15-0) [The Generation Steps](#page-17-0) [Everything is QCD](#page-27-0)

Factorization

Relies on the factorization ansatz.

The cross section and main structure of the event is determined by the hard partonic sub process.

Parton showers and hadronization happens at lower (softer) scales and *dresses* the events without influencing the cross section.

Everything at the LHC is QCD

- ► Any measurement at the LHC requires understanding of **QCD**
- ► Electro-weak processes or BSM processes are easy (although sometimes tedious)
- Even golden signals such as $H \rightarrow 4\mu$ are influenced by QCD
- ▶ Any observable prediction will have QCD corrections $\langle \mathcal{O} \rangle = \sigma_0 (1 + \alpha_s C_1 + \alpha_s^2 C_2 + ...)$
- ► Any signal will have a QCD background
- \triangleright QCD is difficult

[Factorization](#page-15-0) [The Generation Steps](#page-17-0) [Everything is QCD](#page-27-0)

- ► Any signal will have a QCD background
- \triangleright QCD is difficult

Event Generators are all about QCD.

[Factorization](#page-15-0) [The Generation Steps](#page-17-0) [Everything is QCD](#page-27-0)

Why is QCD difficult?

- ► α_s is not very small (\gtrsim 0.1)
- The gluon has a self-coupling and we get alot of gluons
- \blacktriangleright Even if α_{s} is small the phase space for emitting gluons is large. In any α_s expansion the coeficients may be large.
- \triangleright In the end we need hadrons, which are produced in a non-perturbative process.

We need models for parton showers and hadronization

Matrix Element Generation

We always need to start with a $2 \rightarrow n$ matrix element. This can in principle be obtained from the standard model (or BSM) Lagrange density in a straight-forward manner.

However,

- ► On tree-level we have divergencies if the scale ($\sim p_1$) is small. Soft or collinear partons.
- ◮ Beyond leading order we get nasty loops and infinities
- ► If *n* is large, the number of diagrams grows factorially
- ► If *n* is large, it is difficult to find a suitable probability distribution for the momenta

[Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

The Second Commandment of Event Generation

Thou shalt always cover the whole of phase space

4日下

[Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

Simple 2 → 2 **Matrix Elements**

Can in principle be written down by hand from relevant Feynman diagrams.

$$
\sigma = \int dx_1 dx_2 d\hat{t} f_i(x_1, Q^2) f_j(x_2, Q^2) \frac{d\hat{\sigma}_{ij}}{d\hat{t}}
$$

With the parton densities sampled at a scale $Q^2 \sim |\hat{t}| \sim$

2 ⊥ .

 \leftarrow

[Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

Also fairly easy to generate as the integrand is fairly flat in *d* $ln(x_1)$ *d* $ln(x_2)$ *d* $ln(p_\perp^2)$

Note however that $\hat{\sigma}$ is may be divergent as $\hat{t} \to 0$. Eg. Standard QCD ME:

$$
\frac{\partial g}{\partial \theta} = \frac{9\pi \alpha_s^2}{4\hat{s}^2} \left(\frac{\hat{s}^2}{\hat{t}^2} + 2\frac{\hat{s}}{\hat{t}} + 3 + 2\frac{\hat{t}}{\hat{s}} + \frac{\hat{t}^2}{\hat{s}^2} \n+ \frac{\hat{u}^2}{\hat{s}^2} + 2\frac{\hat{u}}{\hat{s}} + 3 + 2\frac{\hat{s}}{\hat{u}} + \frac{\hat{s}^2}{\hat{u}^2} \n+ \frac{\hat{t}^2}{\hat{u}^2} + 2\frac{\hat{t}}{\hat{u}} + 3 + 2\frac{\hat{u}}{\hat{t}} + \frac{\hat{u}^2}{\hat{t}^2} \right)
$$

ś

4日 8

We clearly need a cutoff.

Typically this is given as a jet resolution scale, which for this simple process typically means a *p*⊥-cut.

Eg. the k_{\perp} -algorithm:

Find the pair of particles with smallest

$$
k_{\perp ij} = \frac{\text{min}(k_{\perp i}, k_{\perp j})}{R} \sqrt{\Delta \phi_{ij}^2 + \Delta \eta_{ij}^2}
$$

and cluster them together into one. Or if any *k*⊥*ⁱ* is smaller cluster it to the beam.

Continue until all *clusters* have *k*⊥*ij* and *k*⊥*ⁱ* above some cut.

These remaining jets are then close to the original partons.

[Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

The Third Commandment of Event Generation

4日下

The Third Commandment of Event Generation

4日下

[Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

Higher Order Tree-Level Matrix Elements

We can go on to higher order $2 \rightarrow n$ Matrix Elements. This is in principle straight forward and can even be automated. However the number of diagrams grows ∝ *n*! which makes generation of events forbiddingly slow for *n* >[∼] 8.

Remember also the difficulty in constructing a reasonable probability distribution for the momenta to sample the phase space, especially since there are divergencies everywhere.

► MadGraph/MadEvent

<http://madgraph.hep.uiuc.edu>

 \blacktriangleright . . .

We can use a tree-level $2 \rightarrow 2$ ME to predict an observable such as the rapidity distribution of a jet in a *W*-event.

We can try to get a better estimate by going to higher order tree-level MEs

$$
\langle \mathcal{O} \rangle_{1j} = \sigma_{\rightarrow W+1j}(\mu) \otimes \mathcal{O}(W+j)
$$

$$
\langle \mathcal{O} \rangle_{2j} = \sigma_{\rightarrow W+2j}(\mu) \otimes \mathcal{O}(W+j)
$$

$$
\langle \mathcal{O} \rangle_{3j} = \sigma_{\rightarrow W+3j}(\mu) \otimes \mathcal{O}(W+j)
$$

Where we use some jet-resolution scale μ to cut off divergencies. ∢ □

. .

But we cannot simply add these together, since each cross section is inclusive

The tree-level $ab \rightarrow W + 1j$ matrix element gives the cross section for the production of a *W* plus at least one jet.

Hence it includes also a part of the tree-level $ab \rightarrow W + 2j$ matrix element.

4日 ト

[Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

The Fourth Commandment of Event Generation

Thou shalt never double-count emissions

4日下

[Monte Carlo Integration](#page-3-0) [Matrix Element Generation](#page-30-0) [Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

Next-to-Leading Order

To correctly sum $W + 1j$ and $W + 2j$ contributions to an observable, we need to add virtual contributions to the generated $W + 1j$ states. In that way we get a consistent expansion of the observable.

$$
\langle \mathcal{O} \rangle_{1j} = \alpha_{s} C_{11}(\mu) + \alpha_{s}^{2} C_{12}(\mu)
$$

$$
\langle \mathcal{O} \rangle_{2j} = \alpha_{s}^{2} C_{22}(\mu)
$$

$$
\langle \mathcal{O} \rangle_{\text{NLO}} = \langle \mathcal{O} \rangle_{1j} + \langle \mathcal{O} \rangle_{2j}
$$

4 0 8

[Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

Here the jet resolution scale μ is essential, since the virtual corrections are infinite and negative. But if we add together the 1*j* virtual terms and the unresolved 2*j* contributions, (the contributions below μ) the sum, $\alpha_{\mathrm{s}}^2 \mathcal{C}_{12}(\mu)$ is finite.

 \leftarrow

[Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

The Fifth Commandment of Event Generation

Thou shalt always remember that a NLO generator does not always produce NLO results

4日下

[Event Generators I](#page-0-0) 35 Leif Lönnblad Lund University

Today there are several NLO generators aviablable (cf. next lecture).

They produce few-parton events and you can measure jet observables

Clearly if you have a generator producing $W + 1j$ to NLO, any observable you measure which depends on two jets will only be predicted to leading order.

This can sometimes be tricky. . .

[Event Generators I](#page-0-0) 36 Leif Lönnblad Lund University

[Event Generators I](#page-0-0) 36 Leif Lönnblad Lund University

Today there are several NLO generators aviablable (cf. next lecture).

They produce few-parton events and you can measure jet observables (assuming a parton is a jet (which it isn't)).

Clearly if you have a generator producing $W + 1j$ to NLO, any observable you measure which depends on two jets will only be predicted to leading order.

This can sometimes be tricky. . .

[Event Generators I](#page-0-0) 36 Leif Lönnblad Lund University

[Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

Di-jet decorrelation

1 Measure the azimuthal angle between the two hardest jets. Clearly the 2-jet matrix element will only give back-to back jets, so the three-jet matrix element will give the leading order. And an NLO 3-jet generator will give us NLO.

But for $\phi_{jj} <$ 120°, the two hardest jets needs at least two softer jets to balance. So the NLO becomes LO here.

- Leading order is the first order in α_s which gives a non-zero result for a given observable.
- ► If NLO corrections are large, we need NNLO.
- \blacktriangleright However, chances are that we have a poorly converging series in $\alpha_{\rm s}.$

4日)

 \triangleright This means we need to resum.

All-Order Resummation

Rather than calculating a few terms in the α_s expansion exactly, we can try to approximate all terms.

It turns out that if we just consider the leading divergent part of the cross section, everything exponentiates

$$
\sigma_{0j} = C_{00} + \alpha_{s}C_{01} + \alpha_{s}^{2}C_{02} + \ldots \approx C_{00} \exp(\alpha_{s}C_{01}^{\prime}/C_{00})
$$

\n
$$
\sigma_{1j} = \alpha_{s}C_{11} + \alpha_{s}^{2}C_{12} + \alpha_{s}^{3}C_{13} + \ldots \approx \alpha_{s}C_{11} \exp(\alpha_{s}C_{12}^{\prime}/C_{11})
$$

\n
$$
\vdots
$$

Even if the coefficients diverge as $\mu \to 0$ the exponentiation is finite.

[Tree-Level Matrix Elements](#page-32-0) [Next-to-Leading Order](#page-42-0) [All-Order Resummation](#page-49-0)

The resummation corresponds to obtaining the leading logarithmic contributions to the coefficients

 $\propto \alpha_{\rm s}^{\prime n} \ln(\mu)^{2n}$

This can be done analytically even to next-to-leading log $\propto \alpha_s^n \ln(\mu)^{2n-1}$ and higher.

Or by using parton showers. . .
